12001-12026: *One book to rule them (almost) all!*

Science reveals to us the origin of the Universe and its mechanisms. It shows us the condition of humans (and other species of the animal world to which we belong), why they have so many cognitive and biological (genetic) defects and limitations, how their condition can be improved (or vice versa!) and it also shows us the fate of those who lose themselves in ignorance and in the beliefs of those who base themselves on the facts and the real multifactorial complexity of our environment. Science is not dogmatic, it self-corrects and continually questions itself, it admits to being imperfect by definition, seeks to find fault and establishes that there is very likely no "absolute truths" and that complex systems are rarely dichotomously categorizable. Its precepts are constraining, its stories are verifiable by multiple independent sources and its decisions are always revocable because only the idiots are full of certainties and the wise full of doubts. Study reproducible, peer reviewed Science published in non-predatory journals to gain wisdom, follow its evidence to accept the inevitability of probabilities and causal chains, and apply what it teaches to live a more serene life, be more tolerant of differences and unforeseen events and other probabilistic fatalities. Science contains the light that will guide you in the darkness and comfort you during the manipulation attempts of multiple religions and pseudo-sciences and other charlatans who play on rhetoric monologues and with your feelings to sell you goods, services or ask you for donations and who take advantage of your intellectual weaknesses. Science is the universal traveller's guide, the pilgrim's staff, the sailor's compass, the rationalist's weapon and the sage's charter. Through it, life and its unpredictable, sometimes painful events are relativized and accepted and obscurantism returns to obscurity.

Science is the main subject of this textbook, our good is its main purpose, and the glory of Nature its aim. It should fill our memory and guide our steps through the only, fragile and short life we have. Study it carefully, often, in a spirit of understanding and endless curiosity about complexity. It is a mine of wealth, a subject of exchanges and a river of intellectual delights. It is given to you during your short lifespan and you will take it with you to do as little harm as possible around you until your last moment, hoping that you will transmit its values to your descendants and entourage for the best possible living together. It involves the highest responsibility, will reward the greatest efforts and will condemn to ignorance, intolerance and stupidity all those who will make fun of it.

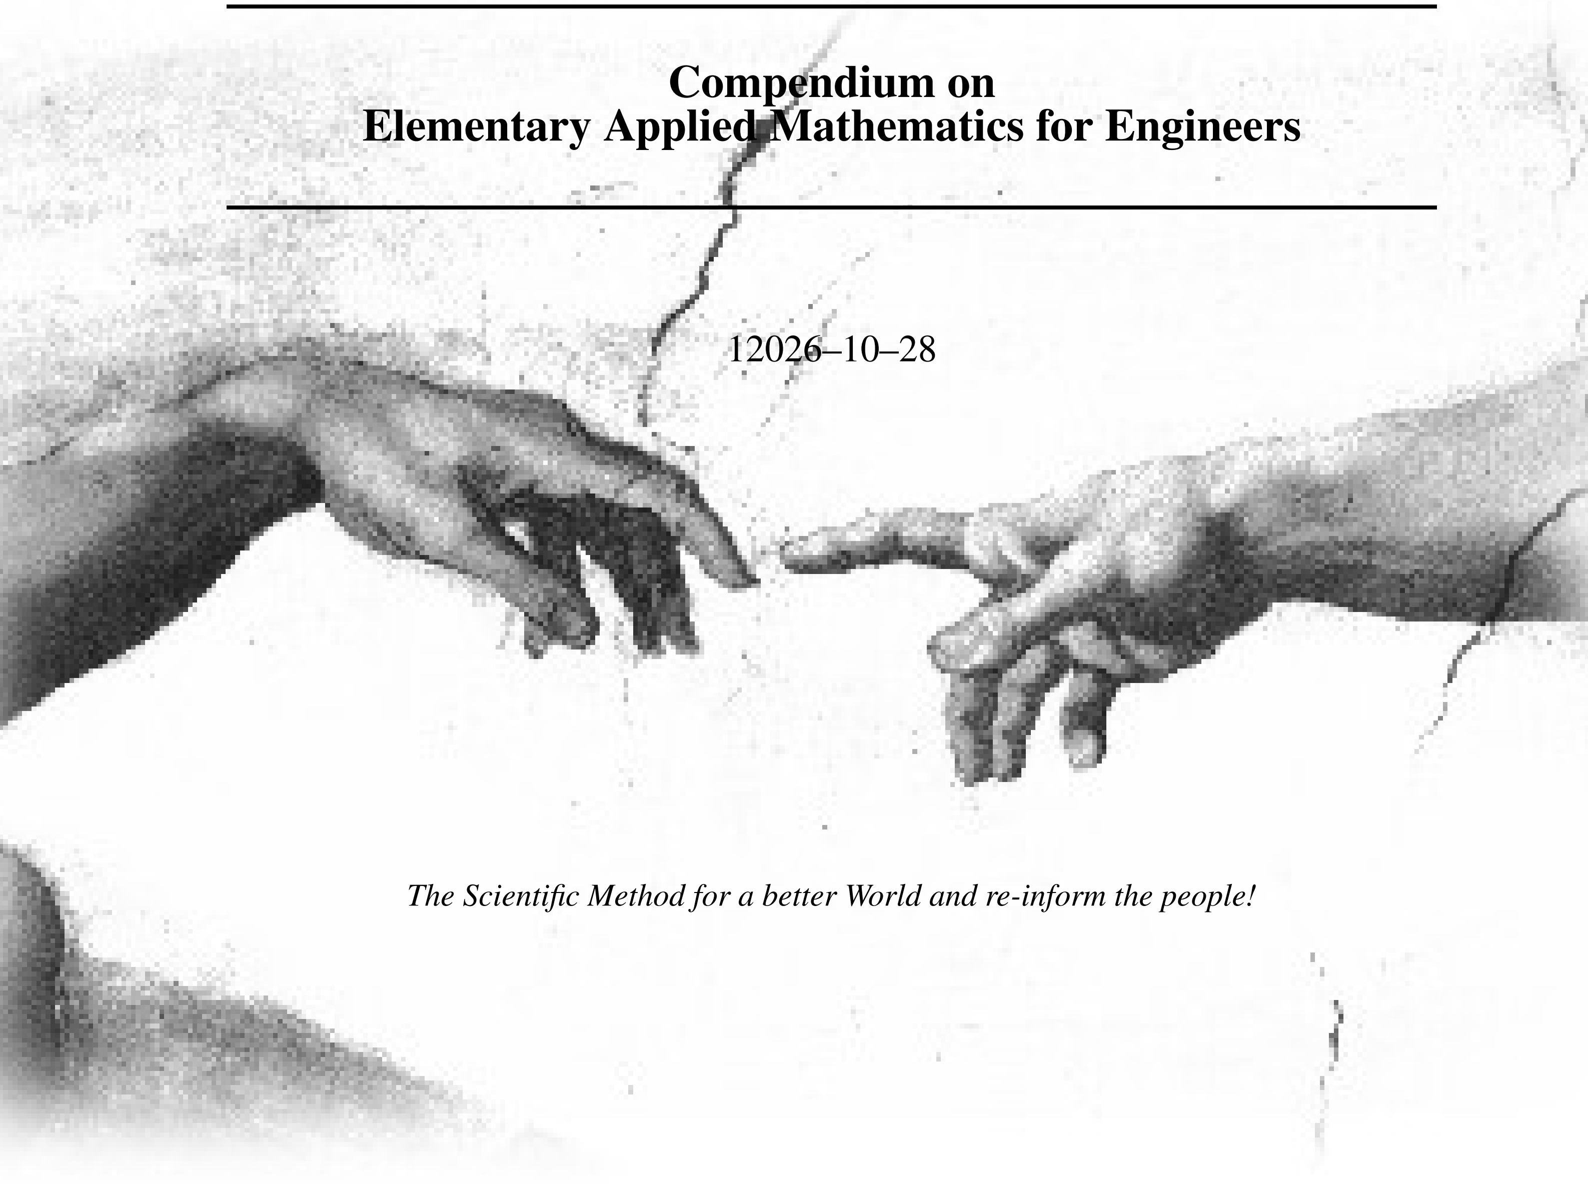
4TH EDITION



Compendium on Elementary Applied Mathematics for Engineers

12026–10–28

The Scientific Method for a better World and re-inform the people!

1

Revision History

The reader will notice that the years are given on the basis of the Holocene calendar for obvious scientific reasons.

Version	Date	Redactor(s)	Description
4.6	12026-06-01	VI	New topics and some small corrections (see changelog at page 9347)
4.5	12025-10-17	VI	New topics and some small corrections (see changelog at page 9347)
4.4	12025-06-06	VI	New topics and some small corrections (see changelog at page 9347)
4.3	12025-05-01	VI	New topics and some small corrections (see changelog at page 9347)
4.2	12024-07-10	VI	New topics and changes in headers and footers (see changelog at page 9347)
4.1	12024-04-21	VI	Some new topics added and a few corrections of typing/translation errors and new illustrations made with TikZ (see changelog at page 9347)
4.0	12023-12-23	VI	Again a few new small topics added and a few corrections of typing/translation errors (see changelog at page 9347)
3.11	12018-06-10	VI, DK	New topics added and a few corrections of typing/translation errors (see changelog at page 9347)
3.10	12018-01-20	VI, DK	New topics added and a few corrections of typing/translation errors (see changelog at page 9347)
3.9	12017-11-13	VI, DK	Some minor updates for the free version of the book (see changelog at page 9347)
3.8	12017-08-01	VI, DK	Some major and critical updates and corrections (see changelog page 9347)
3.7	12017-06-01	VI, DK	French 3^{rd} Edition translation into English finished!
3.6	12017-05-01	VI, DK	French 3^{rd} Edition translation into English. Translation progress $\sim 99\%$

3.5	12017-04-01	VI, DK	French 3rd Edition translation into English. Translation progress $\sim 96\%$
3.4	12017-02-11	VI, DK	French 3rd Edition translation into English. Translation progress $\sim 96\%$
3.3	12016-01-27	VI	French 3rd Edition translation into English. Translation progress $\sim 96\%$
3.0	12014-01-22	VI, RR, LG, HL	French 3rd Edition published on the Internet as PDF ($4,888$ pages).
2.0	12005-03-10	VI, RR	French 2nd Edition published on the Internet as PDF ($2,001$ pages).
1.0	12002-05-01	VI	French 1st Edition published on the Internet as HTML only.

quote 1.0:iv.#1

> ” *If there’s a book that you want to read, but it hasn’t been written yet, then you must write it.* ”

4 Introduction **34**

4.1 Forewords 35

4.1.1 Motivation and goals . . . 41
4.1.2 Who this textbook is intended for . . . 47
4.1.3 How is this textbook structured . . . 49
4.2 Methods . . . 50
4.2.1 Descartes' Method . . . 56
4.2.1.1 Blind studies . . . 58
4.2.2 Research Integrity and Engineering/Scientific Ethics . . . 66
4.2.2.1 Singapore Statement on Research Integrity . . . 66
4.2.2.2 European Code of Conduct for Research Integrity . . . 67
4.2.2.3 Archimedean Oath . . . 68
4.2.3 Scientific Publication Rules (SPR) . . . 70
4.2.4 Scientific Mainstream Media communication . . . 79
4.2.4.1 Social Networks . . . 81
4.2.4.2 Expert Opinions . . . 85
4.3 Vocabulary . . . 88
4.3.1 On Sciences . . . 89
4.3.2 Terminology . . . 99
4.4 Science and Faith . . . 103
4.4.1 Baloney detection kit . . . 109
4.5 Scientific communication backfire . . . 115
4.6 Is Science dogmatic? . . . 120

5 Arithmetic 125

5.1 Proof Theory . . . 131
5.1.1 Foundations Crisis . . . 134
5.1.2 Paradoxes . . . 138
5.1.2.1 Hypothetical-Deductive Reasoning . . . 141
5.1.3 Propositional Calculus . . . 142
5.1.3.1 Propositions (premises) . . . 144
5.1.3.2 Connectors . . . 146
5.1.3.3 Decision procedures . . . 157
5.1.3.3.1 Non-axiomatic procedural decisions . . . 158
5.1.3.3.2 Axiomatic procedural decisions . . . 159
5.1.3.4 Quantifiers . . . 163
5.1.4 Predicate Calculus . . . 167
5.1.4.1 Grammar . . . 168
5.1.4.2 Languages . . . 169
5.1.4.2.1 Symbols . . . 169
5.1.4.2.2 Terms . . . 170
5.1.4.2.3 Formulas . . . 172
5.1.5 Proofs . . . 176
5.1.5.1 Rules of Proofs . . . 177
5.1.6 Laws of thought . . . 187
5.1.6.1 Some famous logical fallacies . . . 199
5.1.6.2 Is logic a science? . . . 204

5.2 Numbers . . . 209
5.2.1 Digital Bases . . . 212
5.2.2 Type of Numbers . . . 215
5.2.2.1 Natural Integer Numbers . . . 215
5.2.2.1.1 Peano axioms . . . 218
5.2.2.1.2 Odd, Even and Perfect Numbers . . . 219
5.2.2.1.3 Prime Numbers . . . 220
5.2.2.2 Relative Integer Numbers . . . 222
5.2.2.3 Rational Numbers . . . 223
5.2.2.4 Irrational Numbers . . . 228
5.2.2.5 Real Numbers . . . 230
5.2.2.5.1 Percentages . . . 234
5.2.2.6 Transfinite Numbers . . . 239
5.2.2.7 Complex Numbers . . . 243
5.2.2.7.1 Geometric Interpretation of Complex Numbers . . . 249
5.2.2.7.1.1 Fresnel Vectors (phasors) . . . 255
5.2.2.7.2 Transformation in the plane . . . 257
5.2.2.8 Quaternion Numbers . . . 261
5.2.2.8.1 Matrix Interpretation of Quaternions . . . 268
5.2.2.8.2 Rotations with Quaternions . . . 269
5.2.2.9 Algebraic and Transcendental Numbers . . . 276
5.2.2.10 Universe Numbers (normal numbers) . . . 279
5.2.2.11 Abstract Numbers (variables) . . . 280
5.2.2.11.1 Domain of a Variable . . . 281
5.3 Arithmetic Operators . . . 285
5.3.1 Binary Relations . . . 286
5.3.1.1 Equalities . . . 287
5.3.1.2 Comparators . . . 288
5.3.2 Fundamental Arithmetic Laws . . . 296
5.3.2.1 Addition . . . 296
5.3.2.2 Subtraction . . . 303
5.3.2.3 Multiplication . . . 308
5.3.2.4 Division . . . 313
5.3.2.5 n-root . . . 320
5.3.3 Arithmetic Polynomials . . . 323
5.3.4 Absolute Value . . . 324
5.3.5 Calculation Rules (operators priorities) . . . 328
5.4 Number Theory . . . 333
5.4.1 Principle of good order . . . 333
5.4.2 Induction Principle . . . 334
5.4.3 Divisibility . . . 336
5.4.3.1 Euclidean Division . . . 338
5.4.3.1.1 Greatest common divisor . . . 340
5.4.3.2 Euclidean Algorithm . . . 343
5.4.3.3 Least Common Multiple . . . 347

5.4.3.4 Fundamental Theorem of Arithmetic . . . 352
5.4.3.5 Congruences (modular arithmetic) . . . 356
5.4.3.5.1 Congruence Class . . . 362
5.4.3.5.2 Complete set of residues . . . 365
5.4.3.5.3 Chinese remainder theorem . . . 366
5.4.3.6 Continued fractions . . . 369
5.5 Set Theory . . . 378
5.5.1 Zermelo-Fraenkel Axiomatic . . . 382
5.5.1.1 Cardinals . . . 388
5.5.1.2 Cartesian Product . . . 391
5.5.1.3 Intervals . . . 392
5.5.2 Set Operations . . . 393
5.5.2.1 Inclusion . . . 394
5.5.2.2 Intersection . . . 394
5.5.2.3 Union . . . 396
5.5.2.4 Difference . . . 397
5.5.2.5 Symmetric Difference . . . 398
5.5.2.6 Product . . . 399
5.5.2.7 Complementarity . . . 399
5.5.3 Functions and Applications . . . 403
5.5.3.1 Cantor-Bernstein Theorem . . . 410
5.5.4 Structures . . . 416
5.5.4.1 Magma . . . 418
5.5.4.2 Monoid . . . 419
5.5.4.3 Groups . . . 421
5.5.4.4 Ring . . . 426
5.5.4.4.1 Sub-ring . . . 429
5.5.4.5 Field . . . 429
5.5.4.6 Vector Spaces . . . 431
5.5.4.7 C-algebra A . . . 433
5.5.4.8 Summary . . . 435
5.5.5 Morphisms . . . 439
5.5.5.1 Ideal . . . 444
5.6 Probabilities . . . 450
5.6.1 Event Universe . . . 452
5.6.1.1 Infinite monkey theorem (Borel's law) . . . 455
5.6.1.1.1 Second Borel-Cantelli lemma . . . 456
5.6.1.2 Do probabilities refute complex structures? . . . 459
5.6.2 Kolmogorov's Axioms . . . 476
5.6.3 Conditional Probabilities . . . 485
5.6.3.1 Conditional Expectation and Variance . . . 499
5.6.3.2 Bayesian Networks . . . 504
5.6.4 Geometric Probabilities . . . 516
5.6.5 Martingales . . . 518
5.6.5.1 Gambling . . . 520

5.6.6 Combinatorial Analysis . . . 522
5.6.6.1 Simple Arrangements with Repetitions . . . 523
5.6.6.2 Simple Permutations without Repetitions . . . 525
5.6.6.3 Simple Permutations with Repetitions . . . 526
5.6.6.4 Simple Arrangements without Repetitions . . . 527
5.6.6.5 Simple Combinations without Repetitions . . . 528
5.6.6.6 Simple Combinations with Repetitions . . . 530
5.6.7 Markov Chains . . . 537
5.7 Statistics . . . 542
5.7.1 Samples . . . 545
5.7.2 Averages . . . 546
5.7.2.1 Laplace Smoothing . . . 570
5.7.2.2 Means and Averages properties . . . 571
5.7.2.2.1 Jensen Inequality . . . 576
5.7.3 Type of variables . . . 580
5.7.3.1 Discrete Variables and Moments . . . 582
5.7.3.1.1 Mean and Variance of Discrete Random Variables . . . 585
5.7.3.1.1.1 Semivariance . . . 598
5.7.3.1.2 Discrete Covariance . . . 599
5.7.3.1.2.1 Quasi-correlation matrix . . . 607
5.7.3.1.2.2 Anscombe's famous quartet . . . 609
5.7.3.1.3 Mean and Variance of the Average . . . 611
5.7.3.1.4 Coefficient of Correlation . . . 613
5.7.3.1.4.1 Geometric interpretation . . . 622
5.7.3.1.4.2 Point biserial correlation coefficient . . . 622
5.7.3.1.4.3 Partial correlation and semipartial correlation . . . 625
5.7.3.1.4.4 Intraclass coefficient of correlation . . . 628
5.7.3.2 Continuous Variables and Moments . . . 633
5.7.3.2.1 Skewness and Kurtosis . . . 636
5.7.4 Fundamental postulate of statistics . . . 643
5.7.5 Diversity Index . . . 644
5.7.6 Distribution Functions (probabilities laws) . . . 647
5.7.6.1 Discrete Uniform Distribution . . . 649
5.7.6.2 Bernoulli Distribution . . . 652
5.7.6.3 Geometric Distribution . . . 654
5.7.6.4 Binomial Distribution . . . 658
5.7.6.5 Negative Binomial Distribution . . . 667
5.7.6.6 Hypergeometric Distribution . . . 672
5.7.6.7 Multinomial Distribution . . . 679
5.7.6.8 Poisson Distribution . . . 686
5.7.6.9 Normal & Gauss-Laplace Distribution . . . 692
5.7.6.9.1 Sum of two random Normal variables . . . 709
5.7.6.9.2 Product of two random Normal variables . . . 711
5.7.6.9.3 Bivariate Normal Distribution . . . 713
5.7.6.9.4 Multivariate Normal distribution . . . 720

5.7.6.9.4.1 Marginal and conditional distributions of multivariate Normal distributions . . . 723
5.7.6.9.5 Normal Reduced Centered Distribution . . . 725
5.7.6.9.6 Henry's Line . . . 726
5.7.6.9.7 Q-Q plot . . . 731
5.7.6.10 Log-Normal Distribution . . . 734
5.7.6.11 Continuous Uniform Distribution . . . 738
5.7.6.12 Triangular Distribution . . . 743
5.7.6.13 Pareto Distribution . . . 746
5.7.6.14 Exponential Distribution . . . 751
5.7.6.15 Cauchy Distribution . . . 755
5.7.6.16 Beta Distribution . . . 760
5.7.6.16.1 Regularized Incomplete beta function integral . . . 764
5.7.6.17 Gamma Distribution . . . 767
5.7.6.17.1 Generalized Gamma Distribution . . . 773
5.7.6.18 Chi-Square (Pearson) Distribution . . . 773
5.7.6.18.1 Noncentral chi-square distribution . . . 780
5.7.6.19 Student Distribution . . . 783
5.7.6.19.1 Multivariate Student T-distribution . . . 789
5.7.6.20 Fisher Distribution . . . 790
5.7.6.21 General Folded Normal Distribution . . . 795
5.7.6.21.1 Half-Normal distribution . . . 796
5.7.6.22 Laplace Distribution . . . 800
5.7.6.23 Benford Distribution . . . 803
5.7.6.24 ex-Gaussian distribution . . . 806
5.7.7 Likelihood Estimators . . . 818
5.7.7.1 Normal Distribution MLE . . . 819
5.7.7.2 Poisson Distribution MLE . . . 825
5.7.7.3 Binomial Distribution MLE . . . 826
5.7.7.4 Geometric Distribution MLE . . . 826
5.7.7.5 Weibull Distribution MLE . . . 827
5.7.7.6 Gamma Distribution MLE . . . 830
5.7.7.7 Pareto Distribution MLE . . . 831
5.7.7.8 Censored data MLE . . . 832
5.7.7.9 Fisher Information Matrix . . . 835
5.7.8 Finite Population Correction Factor . . . 843
5.7.9 Confidence Intervals (inference) . . . 848
5.7.9.1 Frequentist Inference . . . 848
5.7.9.1.1 C.I. on the Mean with known theoretical Variance . . . 852
5.7.9.1.2 C.I. on the Variance with known theoretical Mean . . . 857
5.7.9.1.3 C.I. on the Variance with known empirical Mean . . . 862
5.7.9.1.4 C.I. on the Mean with known empirical Variance . . . 864
5.7.9.1.5 C.I. on the Geometric Mean (for known or unknown Variance) . . . 868
5.7.9.1.6 Binomial exact Test . . . 869
5.7.9.1.7 C.I. for a Proportion . . . 872
5.7.9.1.7.1 Variance stabilizing transformation . . . 878

5.7.9.1.7.2 Test of equality (or difference) of two Proportions . . . 880
5.7.9.1.8 Sign Test . . . 883
5.7.9.1.9 Mood's Median Test . . . 885
5.7.9.1.10 Poisson Test (1 sample) . . . 886
5.7.9.1.11 Poisson Test (2 samples) . . . 889
5.7.9.1.12 Confidence/Tolerance/Prediction/Credibility Intervals . . . 892
5.7.9.2 Bayesian Inference . . . 894
5.7.9.2.1 Beta prior conjugate to Binomial likelihood (beta-binomial distribution) . . . 898
5.7.9.2.1.1 Uninformative prior . . . 901
5.7.9.2.2 Normal prior conjugate to Normal likelihood . . . 904
5.7.9.2.3 Binomial prior conjugate to Binomial likelihood . . . 907
5.7.9.2.4 Credibility Intervals . . . 910
5.7.9.2.5 Bayes Factor (BF) . . . 914
5.7.10 Weak Law of Large Numbers (Khinchin's law) . . . 920
5.7.11 Characteristic Function . . . 926
5.7.11.1 Moment generating function and cumulants . . . 931
5.7.12 Central Limit Theorem . . . 938
5.7.13 Univariate Hypothesis and Adequation Tests (NHST) . . . 944
5.7.13.1 Direction of hypothesis tests and p-values . . . 948
5.7.13.2 Fisher's method for multiple p-values . . . 963
5.7.13.2.1 Simpson's Paradox (sophism) . . . 967
5.7.13.3 Power of a Test . . . 972
5.7.13.3.1 Evidence ("proof") of a negative . . . 974
5.7.13.3.1.1 Two-One-Sided T-test procedure (TOST) . . . 977
5.7.13.3.2 Power of the one sample Z-test and T-test . . . 980
5.7.13.3.3 Power of the two sample Z-test and T-test . . . 983
5.7.13.3.4 Power of the one and two samples P-test . . . 986
5.7.13.3.5 Power calculation based on simulations . . . 990
5.7.13.4 A/B Tests . . . 991
5.7.13.4.1 Naive proportion approach . . . 991
5.7.13.4.2 Fieller's test (ratio of two means) . . . 992
5.7.13.4.3 Bayesian A/B testing for binary outcomes . . . 996
5.7.13.4.4 Bayesian A/B testing for count datas . . . 999
5.7.13.5 Analysis Of VAriance (ANOVA) . . . 1001
5.7.13.5.1 ANOVA with one fixed factor . . . 1004
5.7.13.5.1.1 Welch Test . . . 1020
5.7.13.5.1.2 Contrasts . . . 1024
5.7.13.5.2 ANOVA with two fixed factors without repetitions . . . 1027
5.7.13.5.3 ANOVA with two fixed factors with repetitions . . . 1045
5.7.13.5.4 Multifactor ANOVA with Repeated Measures . . . 1051
5.7.13.5.4.1 Interlude on CRD, RBD, RCBD, IBD, GRBD... . . . 1052
5.7.13.5.4.2 Interlude on Type I, Type II, Type III ANOVAs . . . 1059
5.7.13.5.5 Hierarchical (Nested) ANOVA (HANOVA) . . . 1065
5.7.13.5.6 ANOVA with blocks . . . 1073
5.7.13.5.7 Latin Square ANOVA without repetitions . . . 1074

5.7.13.5.8 Graeco-Latin Square ANOVA 1082
5.7.13.5.9 Multivariate ANOVA (MANOVA) 1091
5.7.13.5.9.1 Hotelling's T-squared Test 1096
5.7.13.6 Equivalence Tests 1101
5.7.13.7 Cochran C-test 1104
5.7.13.8 Family-wise error rate (adjusted p-values) 1106
5.7.13.8.1 Holm-Bonferroni Correction 1109
5.7.13.8.2 Holm–Šidák Correction 1111
5.7.13.9 Adequation Tests (Goodness of Fit tests) 1111

6 Algebra **1344**

6.1 Calculus 1350
6.1.1 Equations and Inequations 1351
6.1.1.1 Equations 1352
6.1.1.2 Inequations 1356
6.1.2 Remarkable Identities 1361
6.1.3 Polynomials 1368
6.1.3.1 General relations between roots and coefficients 1373
6.1.3.2 Multiplication of Polynomials 1374
6.1.3.3 Euclidean Division of Polynomials 1374
6.1.3.4 Factorization Theorem of Polynomials 1377
6.1.3.5 Diophantine equation 1378
6.1.3.6 First order univariate Polynomial and Equations 1379
6.1.3.6.1 Solving by circular reference 1380
6.1.3.7 Second order univariate Polynomial and Equations 1382
6.1.3.7.1 Irrational Equations 1387
6.1.3.7.2 Golden Ratio 1389
6.1.3.8 Third order univariate Polynomial and Equations 1390
6.1.3.9 Fourth order univariate Polynomial and Equations 1394
6.1.3.10 Trigonometric Polynomials 1397
6.1.3.11 Cyclotomic Polynomials 1398
6.1.3.12 Legendre Polynomials 1400
6.1.3.13 Laguerre Polynomials 1404

6.1.3.13.1 Associated Laguerre Polynomials . . . 1411
6.1.3.13.2 Laguerre functions . . . 1414
6.2 Set Algebra . . . 1417
6.2.1 Groups Algebra and Geometry . . . 1417
6.2.1.1 Cyclic Groups . . . 1418
6.2.1.2 Transformations Groups . . . 1421
6.2.1.3 Group of Symmetries . . . 1430
6.2.1.3.1 Orbits and Stabilizers . . . 1434
6.2.1.4 Permutations Groups . . . 1435
6.2.2 Galois Theory . . . 1445
6.2.2.1 Elementary symmetric and Invariant Polynomials . . . 1446
6.2.2.2 General Vieta's formulas . . . 1449
6.3 Differential and Integral Calculus . . . 1450
6.3.1 Differential Calculus . . . 1450
6.3.1.1 Differentials . . . 1464
6.3.1.1.1 Implicit functions . . . 1473
6.3.1.2 Usual Derivatives . . . 1475
6.3.1.3 Implicit Differentiation . . . 1492
6.3.1.4 Smoothness . . . 1496
6.3.2 Integral Calculus . . . 1497
6.3.2.1 Definite Integral . . . 1497
6.3.2.2 Indefinite Integral . . . 1508
6.3.2.3 Double Integral . . . 1518
6.3.2.3.1 Fubini's theorem . . . 1521
6.3.2.4 Integration by Substitution . . . 1522
6.3.2.4.1 Jacobian . . . 1524
6.3.2.5 Integration by Parts . . . 1532
6.3.2.6 Usual Primitives . . . 1534
6.3.2.7 Leibniz integral rule . . . 1560
6.3.2.8 Integral representation of first kind Bessel's function . . . 1564
6.3.2.9 Dirac Function . . . 1569
6.3.2.9.1 Heaviside function . . . 1572
6.3.2.10 Gamma Euler Function . . . 1574
6.3.2.10.1 Incomplete regularized Gamma function . . . 1578
6.3.2.10.2 Euler-Mascheroni Constant . . . 1581
6.3.2.11 Curvilinear Integrals . . . 1583
6.3.2.11.1 Curvilinear Integral of a scalar field . . . 1583
6.3.2.11.2 Curvilinear Integral of a vector field . . . 1584
6.3.2.12 Surface Integrals . . . 1588
6.3.2.13 Integrals involving parametric equations . . . 1593
6.3.2.14 Improper Integrals . . . 1595
6.3.2.15 Elliptic Integrals . . . 1599
6.3.2.15.1 Incomplete Elliptic Integrals . . . 1600
6.3.2.15.2 Complete Elliptic Integrals . . . 1601
6.3.3 Differential Equations . . . 1603

6.3.3.1 First order differential equations . . . 1605
6.3.3.2 Linear differential equations . . . 1605
6.3.3.3 Resolution methods of linear differential equations . . . 1607
6.3.3.3.1 Method of characteristic polynomial . . . 1608
6.3.3.3.1.1 Resolution of the H.E. of the first order L.D.E. with constant coefficients . . . 1609
6.3.3.3.1.2 Resolution of the H.E. of the first order L.D.E. with non-constant coefficients . . . 1609
6.3.3.3.1.3 Resolution of the H.E. of the second order L.D.E. with constant coefficients . . . 1610
6.3.3.3.2 Integrating Factor Method (Euler's Method) . . . 1615
6.3.3.3.3 Method of separation of variables . . . 1617
6.3.3.3.4 Method of constant variation . . . 1618
6.3.3.4 Classification of differential equations . . . 1621
6.3.3.5 Systems of Differential Equations . . . 1627
6.3.3.5.1 Matrix exponentiation method . . . 1627
6.3.3.5.2 Phase space . . . 1633
6.3.3.5.2.1 Stability theory . . . 1636
6.3.3.6 Nonlinear dynamical systems . . . 1644
6.3.3.7 Regular Methods of Perturbations . . . 1645
6.3.3.7.1 Perturbation theory for algebraic equations . . . 1645
6.3.3.7.2 Perturbation theory of differential equations . . . 1647
6.4 Sequences and Series . . . 1651
6.4.1 Sequences . . . 1651
6.4.1.1 Arithmetic Sequences . . . 1653
6.4.1.2 Harmonic Sequences . . . 1655
6.4.1.3 Geometric Sequences . . . 1656
6.4.1.4 Cauchy Sequence . . . 1657
6.4.1.5 Fibonacci Sequence . . . 1661
6.4.1.6 Logic Sequences/Psychologist Sequences . . . 1663
6.4.2 Series . . . 1664
6.4.2.1 Gauss Series . . . 1666
6.4.2.1.1 Bernoulli's Numbers and Polynomials . . . 1669
6.4.2.1.2 Euler-Maclaurin formula . . . 1674
6.4.2.2 Arithmetic Series . . . 1679
6.4.2.3 Geometric Series . . . 1679
6.4.2.3.1 Zeta function and Euler's product formula . . . 1682
6.4.2.4 Telescoping Series . . . 1691
6.4.2.5 Grandi's Series . . . 1691
6.4.2.6 Taylor and Maclaurin Series . . . 1696
6.4.2.6.1 Usual Maclaurin developments . . . 1703
6.4.2.6.2 Taylor series of bivariate functions (multivariate Taylor series) . . . 1714
6.4.2.6.3 Quadratic Form . . . 1717
6.4.2.6.4 Lagrange Remainder . . . 1722
6.4.2.6.5 Taylor Series with Integral Remainder . . . 1724
6.4.2.6.6 Lagrange inversion theorem . . . 1725
6.4.2.7 Fourier Series (trigonometric series) . . . 1727
6.4.2.7.1 Fourier series generative art . . . 1749

6.4.2.7.2 Power of a signal 1756

6.4.2.7.3 Fourier Transform 1758

6.4.2.8 Bessel Series 1768

6.4.2.8.1 Zero order Bessel's Functions 1768

6.4.2.8.2 n order Bessel's Functions 1768

6.4.2.8.3 Bessel's Differential Equations of order n 1774

6.4.3 Convergence Criteria 1775

6.4.3.1 Integral Test 1776

6.4.3.2 D'Alembert Rule 1777

6.4.3.3 Alternating Series Test 1780

6.4.3.4 Fixed Point Theorem 1780

6.4.4 Generating Functions 1783

6.4.4.1 Ordinary Generating Functions (transformation of a sequence into a series) 1783

6.4.4.1.1 Composition of Generating functions 1787

6.4.4.2 Multivariate Generating Functions 1789

6.4.4.3 Functional Generating Functions 1789

6.5 Vector Calculus 1794

6.5.1 Concept of Arrow 1795

6.5.2 Set of Vectors 1797

6.5.2.1 Pseudo-Vectors 1799

6.5.2.2 Normal vector 1801

6.5.2.3 Multiplication by a scalar 1802

6.5.2.3.1 Rule of three 1803

6.5.3 Vector Spaces 1805

6.5.3.1 Linear Combinations 1806

6.5.3.2 Sub-vector spaces 1806

6.5.3.3 Generating families 1807

6.5.3.4 Linear Dependence or Independence 1807

6.5.3.5 Base of a vectorial space 1809

6.5.3.6 Direction Angles 1811

6.5.3.7 Dimensions of a vector space 1812

6.5.3.8 Extension of a free family 1813

6.5.3.9 Rank of a finite family 1813

6.5.3.10 Direct Sums 1814

6.5.3.11 Affine spaces 1815

6.5.4 Euclidean Vector Spaces 1818

6.5.4.1 Scalar Product (Dot Product) 1821

6.5.4.1.1 Cauchy–Schwarz inequality 1826

6.5.4.1.2 Triangle Inequalities 1828

6.5.4.1.3 General Scalar/Dot Product 1829

6.5.4.2 Cross Product 1830

6.5.4.3 Mixed Product (triple product) 1838

6.5.5 Vectorial Functional Space 1840

6.5.6 Hermitian Vector Space 1842

6.5.6.1 Hermitian Inner Product 1843

6.5.6.2 Hermitian Cauchy-Schwarz inequality 1844
6.5.6.3 Types of Vectors Spaces 1845
6.5.7 System of Coordinates 1846
6.5.7.1 Cartesian (rectangular) Coordinate System 1846
6.5.7.2 Spherical Coordinate System 1849
6.5.7.2.1 Orthodromic distance 1854
6.5.7.2.2 Haversine distance 1858
6.5.7.3 Cylindrical Coordinate System 1861
6.5.7.4 Polar Coordinate System 1863
6.5.8 Differential Operators 1866
6.5.8.1 Gradients of Scalar Field 1869
6.5.8.2 Gradients of Vector Field 1878
6.5.8.3 Divergences of a Vector Field 1879
6.5.8.4 Rotationals of a Vector Field (Curl) 1888
6.5.8.5 Laplacians of Scalar Fields (Laplace Operator) 1899
6.5.8.6 Laplacians of Vector Fields 1903
6.5.8.7 Remarkable Identities 1911
6.5.8.8 Summary 1918
6.6 Linear Algebra 1924
6.6.1 Linear Systems 1929
6.6.2 Linear Transformations 1934
6.6.3 Matrices 1936
6.6.3.1 Rank of a matrix 1938
6.6.3.2 Matrix Algebra 1945
6.6.3.3 Type of Matrices 1948
6.6.3.4 Determinant 1961
6.6.3.4.1 Derivative of a Determinant relatively to a parameter 1974
6.6.3.4.2 Derivative of logarithm of a determinant 1976
6.6.3.4.3 Cramer’s rule 1977
6.6.3.4.4 Determinant Cofactor and Matrix Inverse 1980
6.6.3.4.5 Determinant of block-diagonal or block-triangular matrices 1986
6.6.3.4.6 Inverse and Determinant of a partitioned symmetric matrix 1989
6.6.4 Change of Basis (frames) 1992
6.6.5 Eigenvalues and Eigenvectors 1997
6.6.5.1 Rotation Matrices and Eigenvalues 2001
6.6.6 Spectral Theorem 2004
6.6.7 Matrix Decompositions 2011
6.6.7.1 Singular Value Decomposition (SVD) 2011
6.6.7.1.1 Singular Vectors and Values 2013
6.6.7.1.2 Special case of SVD for symmetric matrices 2020
6.6.7.1.3 Orthogonal decomposition (eigenvalue spectral decomposition) 2022
6.6.7.2 LU Decomposition 2024
6.6.7.3 Cholesky’s Decomposition 2027
6.6.7.4 QR Decomposition 2030
6.6.8 Woodbury Matrix identity and Sherman-Morrison relation 2035

6.7 Tensor Calculus . . . 2038
6.7.1 Tensor . . . 2039
6.7.2 Indicial Notation . . . 2042
6.7.2.1 Summation on multiple index . . . 2044
6.7.2.2 Kronecker Symbol . . . 2044
6.7.2.3 Antisymmetric Symbol (Levi-Civita symbol) . . . 2045
6.7.3 Metric and Signature . . . 2051
6.7.4 Gram's Determinant . . . 2054
6.7.5 Contravariant and Covariant Components . . . 2059
6.7.6 Operation in Basis . . . 2062
6.7.6.1 Gram-Schmidt Orthogonalization Method . . . 2062
6.7.6.2 Change of Basis . . . 2066
6.7.6.3 Reciprocal Basis (Dual Basis) . . . 2067
6.7.7 Euclidean Tensors (cartesian tensor) . . . 2071
6.7.7.1 Fundamental Tensor . . . 2072
6.7.7.2 Tensor product (dyadic) of two vectors and matrices . . . 2073
6.7.7.3 Tensor Spaces . . . 2076
6.7.7.4 Linear combination of tensors . . . 2080
6.7.7.5 Contraction of indices . . . 2080
6.7.7.5.1 Raising and lowering indices . . . 2081
6.7.8 Special Tensors . . . 2085
6.7.8.1 Symmetric Tensor . . . 2085
6.7.8.2 Antisymmetric Tensor . . . 2088
6.7.8.3 Fundamental Tensor . . . 2091
6.7.9 Curvilinear Coordinates . . . 2091
6.7.9.1 Natural basis in spherical coordinates (curvilinear basis in spherical coordinates) . . . 2097
6.7.9.2 Natural basis in polar coordinates (curvilinear basis in polar coordinates) . . . 2099
6.7.9.3 Natural basis in cylindrical coordinates (cylindrical basis in polar coordinates) . . . 2099
6.7.10 Christoffel symbols . . . 2103
6.7.11 Ricci Theorem . . . 2112
6.7.12 Riemann-Christoffel symbols . . . 2122
6.7.13 Ricci curvature (Ricci tensor) . . . 2127
6.7.14 Einstein Tensor . . . 2141
6.8 Spinor Calculus . . . 2145
6.8.1 Unit Spinor . . . 2146
6.8.2 Geometric Properties . . . 2152
6.8.2.1 Plane Symmetries . . . 2153
6.8.2.2 Rotations . . . 2155
6.8.2.3 Properties of Pauli Matrices . . . 2161
7 Analysis **2168**
7.1 Functional Analysis . . . 2170
7.1.1 Representations . . . 2171
7.1.1.1 Tabular Representations . . . 2171
7.1.1.2 Graphical Representations . . . 2177

7.1.1.2.1 2D representations . . . 2178
7.1.1.2.2 3D representations . . . 2186
7.1.1.2.3 2D Vector representations . . . 2193
7.1.1.2.4 Properties of visual representations . . . 2196
7.1.1.3 Analytical Representations . . . 2206
7.1.2 Functions . . . 2209
7.1.2.1 Limits and Continuity of functions . . . 2226
7.1.2.1.1 Squeeze theorem . . . 2239
7.1.2.1.2 Usual Limits (and Continuities) . . . 2242
7.1.2.1.3 Limit laws . . . 2268
7.1.2.1.4 Asymptotes . . . 2269
7.1.2.1.5 Discontinuities . . . 2276
7.1.2.2 Concavity/Convexity of a function . . . 2280
7.1.2.3 Euler theorem for homogeneous functions . . . 2282
7.1.3 Logarithms . . . 2284
7.1.4 Convolutions . . . 2293
7.1.4.1 Continuous and Discrete Linear Convolution Product . . . 2293
7.1.4.2 Matrix Convolution . . . 2299
7.1.5 Integral Transforms . . . 2303
7.1.5.1 Fourier Transform . . . 2305
7.1.5.1.1 Continuous Time Fourier Transform . . . 2305
7.1.5.1.1.1 Properties of Fourier Transform . . . 2309
7.1.5.1.1.2 Usual Fourier transforms . . . 2319
7.1.5.1.2 Discrete Time Fourier Transform . . . 2327
7.1.5.1.3 Properties of Discrete Fourier Transform . . . 2329
7.1.5.2 Laplace Transform . . . 2336
7.1.5.2.1 Inverse Laplace Transform . . . 2339
7.1.5.2.2 Region of Convergence . . . 2340
7.1.5.2.3 Zeros and Poles of Laplace Transform . . . 2342
7.1.5.2.4 Properties of region of convergence . . . 2343
7.1.5.2.5 Properties of Laplace Transform . . . 2345
7.1.5.2.6 Usual Laplace transforms . . . 2348
7.1.5.2.7 Solving differential systems . . . 2356
7.1.5.2.8 Unilateral Laplace Transform . . . 2358
7.1.5.3 $\mathcal{Z}$-Transform . . . 2360
7.1.5.3.1 Transfer function of LTI system . . . 2363
7.1.5.3.2 Conformal mapping between s-plane to z-plane . . . 2363
7.1.5.3.3 Region of Convergence . . . 2364
7.1.5.3.4 Zeros and Poles of $\mathcal{Z}$-Transform . . . 2366
7.1.5.3.5 Properties of $\mathcal{Z}$-Transform . . . 2367
7.1.5.3.6 Usual $\mathcal{Z}$-Transforms . . . 2371
7.1.5.3.7 Unilateral $\mathcal{Z}$-Transform . . . 2373
7.1.5.4 Hilbert Transform . . . 2376
7.1.6 Functional dot product (inner product) . . . 2379
Orthogonality of trigonometric functions . . . 2380

Orthogonality of complex exponential functions 2382
Orthogonality of Bessel functions 2382
Orthogonality of Hermite polynomial 2385
Orthogonality of Laguerre polynomial 2386
Orthogonality of Legendre polynomial 2387
7.1.6.1 Cauchy-Schwarz inequality for integrals 2388
7.2 Complex Analysis 2390
7.2.1 Linear Applications 2390
7.2.2 Holomorphic Functions 2399
7.2.2.1 Orthogonality of real and imaginary iso-curves 2405
7.2.3 Complex Logarithm 2407
7.2.4 Complex Integral Calculus 2411
7.2.4.1 Convergence of a complex series 2418
7.2.5 Path Decomposition 2427
7.2.5.1 Inverse Path 2428
7.2.6 Laurent Series 2430
7.2.7 Singularities 2437
7.2.8 Residue Theorem 2440
7.2.8.1 Pole at infinity 2444
7.3 Topology 2446
7.3.1 General Topology 2447
7.3.1.1 Topological Spaces 2448
7.3.2 Metric Space and Distance 2450
7.3.2.1 Equivalent Distances 2457
7.3.2.2 Lipschitz Functions 2457
7.3.2.3 Continuity and Uniform Continuity 2460
7.3.3 Opened and Closed Set 2463
7.3.3.1 Balls 2464
7.3.3.2 Partitions 2467
7.3.3.3 Formal Ball 2470
7.3.3.4 Diameter 2470
7.3.4 Varieties 2473
7.3.4.1 Subvariety 2475
7.3.4.2 Surfaces Homeomorphism 2476
7.3.4.3 Differential Varieties 2479
7.4 Measure Theory 2481
7.4.1 Measurable Spaces 2482
7.4.1.1 Monotone Classes 2491
7.4.2 Lebesgue measure in probabilities 2493
7.4.2.1 Lebesgue Measure of the rational and irrational numbers 2496

8 Geometry 2499

8.1 Trigonometry 2503
8.1.1 Radian 2503
8.1.2 Circle Trigonometry 2508

8.1.2.1 Remarkable trigonometric triangle identities . . . 2519
8.1.2.1.1 Laws of Cosines (cosine rule) . . . 2524
8.1.2.1.2 Laws of Sines (sine rule) . . . 2528
8.1.3 Hyperbolic Trigonometry . . . 2532
8.1.3.1 Remarkable hyperbolic identities . . . 2539
8.1.4 Spherical Trigonometry . . . 2542
8.1.4.1 Girard's theorem . . . 2546
8.1.4.2 Four-parts formula . . . 2548
8.1.5 Solid Angle . . . 2549
8.2 Euclidean Geometry . . . 2553
8.2.1 Objects of Euclidean Geometry . . . 2553
8.2.1.1 Dimensions . . . 2555
8.2.2 Euclid's Constructions . . . 2563
8.2.2.1 Segments and Lines . . . 2566
8.2.2.1.1 Quantities of the same type . . . 2568
8.2.3 Plane Geometry . . . 2573
8.2.3.1 Displacements and Turnarounds . . . 2574
8.2.3.2 Plane angles . . . 2575
8.2.3.2.1 Angle Measurements . . . 2583
8.2.3.2.2 Units of Angle Measurements . . . 2586
8.2.3.2.3 Bisector . . . 2591
8.2.3.3 Triangles . . . 2593
8.2.3.3.1 Equal Triangles (congruent triangles) . . . 2594
8.2.3.3.2 Isosceles Triangles . . . 2597
8.2.3.3.3 Equilateral Triangles . . . 2601
8.2.3.3.4 Right Triangle . . . 2601
8.2.3.3.5 Right Isosceles Triangle . . . 2603
8.2.3.3.6 Inequalities in the triangles . . . 2605
8.2.3.3.7 Triangles remarkable interior lines . . . 2607
8.2.3.3.8 Pythagorean theorem . . . 2609
8.2.3.3.9 Thales' Theorem (intercept theorem) . . . 2610
8.2.3.3.9.1 Euclid's (triangle) theorem . . . 2615
8.2.3.4 Parallelism . . . 2618
8.2.3.5 Circle . . . 2620
8.2.3.5.1 Circumscribed circle theorem . . . 2623
8.2.3.5.2 Inscribed circle theorem . . . 2624
8.2.3.5.3 Thales' theorem of the circle . . . 2626
8.2.3.5.4 Central angle theorem . . . 2627
8.2.4 Hilbert's Axioms . . . 2631
8.2.4.1 Incidence Axioms (axioms of association) . . . 2632
8.2.4.2 Order Axioms . . . 2632
8.2.4.3 Congruence Axioms . . . 2633
8.2.4.4 Continuity Axioms . . . 2633
8.2.4.5 Parallels Axioms . . . 2634
8.2.5 Barycenter (centroid) . . . 2635

8.2.6 Geometric Transformations . . . 2640
8.2.6.1 Translation . . . 2642
8.2.6.2 Homothety (scaling) . . . 2643
8.2.6.3 Shear (skew) transformation . . . 2645
8.2.6.4 Rotation . . . 2647
8.2.6.4.1 Gimbal lock . . . 2652
8.2.6.4.2 Euler angles . . . 2656
8.2.6.5 Reflection . . . 2659
8.3 Non-Euclidean Geometry . . . 2663
8.3.1 Curvature(s) . . . 2665
8.3.2 Axioms of non-euclidean geometry . . . 2667
8.3.3 Generalized angle sum theorems . . . 2668
8.3.4 Geodesic and Metric Equation . . . 2669
8.3.5 Riemann Spaces . . . 2673
8.4 Projective Geometry . . . 2679
8.4.1 Conical Perspective (Central Perspective) . . . 2680
8.4.1.1 Images of Points . . . 2684
8.4.1.2 Images of Straight Lines . . . 2701
8.4.2 Affine projections . . . 2712
8.4.2.1 Isometric perspective . . . 2714
8.4.2.2 Oblique perspective . . . 2720
8.4.2.3 Orthogonal projection . . . 2722
8.4.3 Spherical projections . . . 2727
8.4.3.1 Stereographic projection . . . 2729
8.4.3.2 Cylindrical projection . . . 2738
8.4.3.3 Mercator projection . . . 2739
8.4.3.4 Lambert's equivalent projection (Peters projection) . . . 2743
8.4.3.5 Mollweide projection . . . 2746
8.4.4 Other perspectives and Laws of linear perspective . . . 2751
8.4.5 Homogeneous Coordinates (projection coordinates) . . . 2759
8.4.5.1 $\mathcal{P}^2$ Projective Space . . . 2759
8.4.5.2 $\mathcal{P}^3$ Projective Space . . . 2761
8.5 Analytical Geometry . . . 2764
8.5.1 Conics . . . 2764
8.5.1.1 Algebraic approach . . . 2765
8.5.1.2 Geometric Approach . . . 2775
8.5.1.3 Dandelin Theorem (Dandelin spheres) . . . 2793
8.5.1.4 Classification of conical by the determinant . . . 2794
8.5.2 Parametrizations . . . 2800
8.5.2.1 Equation of the Plane . . . 2800
8.5.2.2 Equation of the Straight line . . . 2804
8.5.2.2.1 Distance from a line to a point . . . 2807
8.5.2.2.2 Line defined by the intersection of planes . . . 2808
8.5.2.2.3 Parametric equation of a line in $\mathbb{R}^3$ . . . 2809
8.5.2.3 Equation of a Circle . . . 2810

8.5.2.4 Equation of a Square . . . 2812
8.5.2.5 Equation of an Hexagon . . . 2813
8.5.2.6 Equation of a Cycloid . . . 2814
8.5.2.7 Equation of an Epicycloid . . . 2816
8.5.2.8 Equation of a Spiral . . . 2818
8.5.2.9 Equation of a Hypocycloid . . . 2821
8.5.2.10 Surface of revolution . . . 2823
8.5.2.10.1 Cone . . . 2823
8.5.2.10.2 Sphere . . . 2825
8.5.2.10.2.1 Great circle of sphere . . . 2828
8.5.2.10.2.2 n-Sphere volume . . . 2829
8.5.2.10.3 Ellipsoid (spheroid) . . . 2834
8.5.2.10.4 Cylinder . . . 2837
8.5.2.10.5 Paraboloid . . . 2839
8.5.2.10.6 Hyperboloid . . . 2841
8.5.2.10.7 Torus . . . 2848
8.6 Differential Geometry . . . 2850
8.6.1 Parametric Curves . . . 2850
8.6.2 Isolines . . . 2857
8.6.3 Frenet Frame . . . 2863
8.6.4 Surface Patches . . . 2878
8.6.4.1 Metric of a Surface Patch . . . 2879
8.6.4.1.1 Regularity of a Surface . . . 2882
8.7 Geometric Shapes . . . 2886
8.7.1 Usual Surfaces (areas) . . . 2888
8.7.1.1 Polygons . . . 2888
8.7.1.2 Rectangle . . . 2894
8.7.1.3 Square . . . 2895
8.7.1.4 Unspecified Triangle . . . 2896
8.7.1.5 Isosceles Triangle . . . 2900
8.7.1.6 Equilateral Triangle . . . 2902
8.7.1.7 Right Triangle . . . 2905
8.7.1.8 Trapezoid . . . 2906
8.7.1.9 Parallelogram . . . 2908
8.7.1.10 Hexagon . . . 2909
8.7.1.11 Rhombus . . . 2914
8.7.1.12 Circle . . . 2915
8.7.1.13 Ellipse . . . 2917
8.7.1.13.1 Ellipse section surface . . . 2920
8.7.2 Usual Volumes . . . 2923
8.7.2.1 Polyhedron . . . 2924
8.7.2.1.1 Parallelepiped . . . 2925
8.7.2.1.1.1 Moment of Inertia of a rectangular plate . . . 2926
8.7.2.1.1.2 Moment of Inertia of a triangular plate . . . 2929
8.7.2.1.2 Pyramid . . . 2931

8.7.2.1.2.1 Moment of Inertia of a regular square pyramid . . . 2932
8.7.2.1.3 Right Prism . . . 2933
8.7.2.1.4 Regular Polyhedron . . . 2934
8.7.2.1.5 Regular Tetrahedron . . . 2939
8.7.2.1.6 Regular hexahedron (cube) . . . 2942
8.7.2.1.7 Regular octahedron . . . 2943
8.7.2.1.8 Regular Icosahedron . . . 2947
8.7.2.1.9 Regular Dodecahedron . . . 2951
8.7.2.2 Usual Solids of Revolution . . . 2956
8.7.2.2.1 Cylinder . . . 2959
8.7.2.2.2 Cone . . . 2963
8.7.2.2.3 Sphere . . . 2964
8.7.2.2.3.1 Spherical cap surface . . . 2969
8.7.2.2.3.2 Sphere packing . . . 2970
8.7.2.2.4 Torus . . . 2973
8.7.2.2.5 Ellipsoid (spheroid) . . . 2977
8.7.2.2.6 Paraboloid . . . 2983
8.7.2.2.7 Gabriel's horn . . . 2986
8.7.2.2.8 Wine Barrel with Circular Section . . . 2987
8.7.3 Isoperimetric inequality (2D) . . . 2993
8.8 Graph Theory . . . 2999
8.8.1 Type of Graphs and Structures . . . 3000
8.8.2 Graph Adjacency Matrix . . . 3026
8.8.3 Categories . . . 3031
8.9 Knot Theory . . . 3035
8.9.1 Braids Representation . . . 3035
8.9.1.1 Braids Group . . . 3037
8.9.2 Knot Representation . . . 3040
8.9.2.1 Knots Group . . . 3044
8.9.3 Tait's Knot . . . 3048
8.9.4 Mathematical Formalisation . . . 3052
8.9.4.1 Planar Representation . . . 3061

9 Mechanics 3063

9.1 Principia . . . 3068
9.1.1 System of Units . . . 3072
9.1.1.1 Dimensional Analysis . . . 3081
9.1.1.1.1 Time . . . 3083
9.1.1.1.2 Length . . . 3085
9.1.1.1.3 Mass . . . 3087
9.1.1.1.4 Energy . . . 3092
9.1.1.1.5 Electric Charge . . . 3095
9.1.1.2 Scientific Notation and Metric Prefixes . . . 3098
9.1.1.3 Scales of Measurements . . . 3101
9.1.2 Distributions . . . 3112

9.1.3 Constants 3113
9.1.3.1 Mathematical Constants 3114
9.1.3.2 Universal Constants (fundamental constants) 3114
9.1.3.3 Astronomical/Astrophysical parameters and constants 3119
9.1.3.4 Chemical parameters 3119
9.1.3.5 Material parameters 3121
9.1.3.6 Planck's constants 3122
9.1.4 Principles of Physics 3127
9.1.4.1 Principle of Causality 3128
9.1.4.2 Principle of Conservation of Energy 3129
9.1.4.3 Principle of Least Action 3131
9.1.4.4 Noether's Principle (Noether's theorem) 3132
9.1.4.4.1 Invariance by translation in space 3134
9.1.4.4.2 Invariance by rotation in space 3136
9.1.4.4.3 Invariance by translation in time 3136
9.1.4.4.4 Noether's theorem 3139
9.1.4.5 Curie's Principle 3144
9.1.5 Point Spaces 3145
9.2 Analytical Mechanics 3152
9.2.1 Lagrangian formalism 3155
9.2.1.1 Generalized coordinates and frames 3156
9.2.1.2 Variational Principle 3160
9.2.1.3 Euler-Lagrange Equation 3162
9.2.1.3.1 Beltrami Identity 3177
9.2.1.3.2 Theorem of Variational Calculus 3178
9.2.2 Canonical Formalism 3180
9.2.2.1 Legendre Transform 3180
9.2.2.2 Hamiltonian 3181
9.2.2.3 Poisson bracket 3189
9.2.2.4 Canonical transformations 3192
9.3 Classical Mechanics 3194
9.3.1 Newton's laws 3199
9.3.1.1 Newton's first law (Inertia law) 3199
9.3.1.2 Newton's second law (Fundamental Principle of Dynamics) 3202
9.3.1.3 Newton's third law (Law of Action and Reaction) 3209
9.3.2 Center of Mass and Reduced Mass 3213
9.3.2.1 Center of Mass Theorem 3216
9.3.2.2 Guldin's Theorem 3221
9.3.3 Kinematics of Rectilinear Motion 3224
9.3.3.1 Position 3225
9.3.3.2 Velocity and speed 3225
9.3.3.2.1 Motion parallax 3229
9.3.3.3 Acceleration 3231
9.3.3.3.1 Osculator Plane 3237
9.3.3.4 Galilean Relativity Principle 3239

9.3.4 Angular Momentum 3244
9.3.4.1 Moments 3251
9.3.5 Static Forces 3256
9.3.5.1 Lami's theorem 3261
9.3.6 Ballistics 3263
9.3.6.1 Ballistic equation without friction 3265
9.3.6.2 Ballistic equation with friction 3269
9.3.6.3 Ballistic accounting Earth's curvature 3271
9.3.7 Kinematics of Circular Motion (rotational kinematics) 3280
9.3.8 Energy, Work and Power 3293
9.3.8.1 Conservative vector field 3294
9.3.8.2 Kinetic Energy 3297
9.3.8.2.1 Moment of inertia 3297
9.3.8.2.2 Euler's rotation equation 3317
9.3.8.2.2.1 Derivation in the stationary reference frame 3319
9.3.8.2.2.2 Derivation in the body reference frame 3320
9.3.8.2.3 Gyroscope 3324
9.3.8.2.3.1 Classical Approach with precession only 3326
9.3.8.2.3.2 Lagrangian Approach with precession and nutation 3332
9.3.8.2.4 König's kinetic and angular momentum theorems 3347
9.3.8.2.4.1 First König's Theorem (König's angular momentum theorem) 3348
9.3.8.2.4.2 Second König's Theorem (König's kinetic energy theorem) 3349
9.3.8.3 Gravitational Potential Energy 3351
9.3.8.3.1 Gravitational Potential Energy of a Material Sphere 3356
9.3.8.3.2 Gravitational Effective potential 3358
9.3.8.4 Conservation of Total Mechanical Energy 3360
9.3.8.4.1 Generalized Newton law 3362
9.3.8.5 Conservation of Linear Momentum 3367
9.3.8.5.1 Elastic Collision in 1-dimensions 3369
9.3.8.5.2 Elastic Collision in 2-dimensions 3371
9.3.8.5.3 Inelastic Collision in 2-dimensions 3372
9.3.8.5.4 Rebound (stacked ball drop) 3374
9.3.8.6 Power 3379
9.3.8.6.1 Power of a turning machine 3381
9.3.8.6.1.1 Power yield 3381
9.3.9 Relative Movements and Inertial Forces 3383
9.3.9.1 Coriolis force and deflection magnitude 3391
9.3.9.1.1 Coriolis deviation of free falling objects 3396
9.3.9.2 Eötvös effect 3398
9.3.10 Oscillating Movements 3403
9.3.10.1 Newton's cradle 3403
9.3.10.2 Simple Pendulum (mass-wire pendulum) 3405
9.3.10.3 Physical Pendulum 3413
9.3.10.4 Elastic Pendulum (mass-spring pendulum) 3416
9.3.10.4.1 One degree of freedom elastic pendulum with/without friction 3416

9.3.10.4.2 Harmonic oscillator (Lorentz oscillator) . . . 3421
9.3.10.4.3 Two degrees of freedom elastic pendulum without friction . . . 3421
9.3.10.5 Conical Pendulum . . . 3423
9.3.10.6 Torsion Pendulum . . . 3425
9.3.10.7 Foucault's Pendulum . . . 3426
9.3.10.8 Huygens' Pendulum (and brachistochrone curve) . . . 3433
9.3.10.9 Double Pendulum . . . 3440
9.3.10.10 Triple linear coupled pendulum . . . 3446
9.3.10.11 Inverted Pendulum . . . 3448
9.3.11 Tribology . . . 3452
9.3.11.1 Exponential Friction . . . 3462
9.3.11.2 Horizontal Viscous Friction . . . 3465
9.3.11.3 Vertical Viscous Friction . . . 3466
9.3.11.4 Stokes' Vertical Viscous Friction . . . 3467
9.3.11.5 Stokes' Horizontal Viscous Friction . . . 3470
9.3.11.6 Friction's Heat Factor . . . 3473
9.4 Wave Mechanics . . . 3475
9.4.1 Wave Function . . . 3475
9.4.2 Wave Equation . . . 3476
9.4.3 Type of Waves . . . 3478
9.4.3.1 Periodic Waves . . . 3478
9.4.3.2 Harmonic Waves . . . 3479
9.4.3.2.1 Phase velocity and Group velocity . . . 3481
9.4.3.3 Stationary Waves . . . 3483
9.4.3.4 Vibration Modes in a Stretched String . . . 3486
9.4.3.4.1 Dirichlet Conditions . . . 3488
9.4.3.4.2 Neumann Conditions . . . 3495
9.4.4 Non-relativistic Lagrangian of a String . . . 3496
9.4.5 Vibrational modes of a circular membrane . . . 3500
9.4.6 Phasors . . . 3510
9.4.7 Superposition of periodic waves . . . 3517
9.4.7.1 AM/FM Broadcasting . . . 3523
9.5 Statistical Mechanics . . . 3525
9.5.1 Statistical Information Theory . . . 3525
9.5.1.1 High Entropy Structures . . . 3536
9.5.1.2 Usual Shannon entropies . . . 3538
9.5.1.3 Perplexity . . . 3541
9.5.1.4 Kullback–Leibler divergence . . . 3542
9.5.2 Boltzmann law . . . 3549
9.5.3 Statistical Physics Distributions . . . 3554
9.5.3.1 Maxwell Distribution (velocity distribution) . . . 3554
9.5.3.2 Maxwell-Boltzmann Distribution . . . 3561
9.5.3.3 Boltzmann Distribution . . . 3568
9.5.3.4 Fermi-Dirac Distribution . . . 3571
9.5.3.5 Bose-Einstein Distribution . . . 3576

9.5.4 Brownian Motion (random walk) 3582
9.6 Thermodynamics 3597
9.6.1 Thermodynamic Variables 3599
9.6.2 Thermodynamics Systems 3602
9.6.3 Thermodynamic Transformations 3603
9.6.4 State Variables 3607
9.6.4.1 Phases 3609
9.6.5 Equation of State 3611
9.6.5.1 Ideal Gas law 3612
9.6.5.2 State equation of a Liquid 3613
9.6.5.3 State equation of Solids 3615
9.6.6 Laws of Thermodynamics 3618
9.6.7 Calorific Capacities (heat capacity) 3622
9.6.7.1 Newton's Law of Cooling 3635
9.6.8 Internal Energy 3637
9.6.8.1 Work (energy) of Mechanical Forces 3641
9.6.8.2 Enthalpy 3643
9.6.8.3 Laplace's law 3646
9.6.8.4 Saint-Venant Thermodynamic Equation 3651
9.6.8.5 Thermoelastics coefficients 3653
9.6.9 Heat 3656
9.6.9.1 Entropy 3658
9.6.9.1.1 Life, evolution, and the second law of thermodynamics 3665
9.6.9.1.2 Heat Flow 3666
9.6.9.2 Carnot Cycle 3668
9.6.10 Maxwell relations 3672
9.6.11 Continuity Equation 3679
9.6.11.1 Heat Equation 3684
9.6.11.1.1 Fick's laws of diffusion 3698
9.6.12 Thermal radiation 3703
9.6.12.1 Black Body radiation 3704
9.6.12.1.1 Stefan–Boltzmann law 3706
9.6.12.1.2 Planck's law 3716
9.6.12.2 Summing up all types of heat transfer 3731
9.7 Continuum Mechanics 3734
9.7.1 Rigid Bodies 3735
9.7.1.1 Pressures 3735
9.7.1.2 Elasticity of Solids 3738
9.7.1.2.1 Hooke's law 3744
9.7.1.2.2 Shear Modulus 3751
9.7.1.2.3 Compressibility Modulus (bulk modulus) 3760
9.7.1.2.4 Flexural Modulus (bending modulus) 3762
9.7.1.2.5 Tranverse Wave in Solids 3765
9.7.2 Liquids (fluid mechanics) 3770
9.7.2.1 Pascal's Theorem 3773

9.7.2.2 Viscosity . . . 3775
9.7.2.2.1 Poiseuille's law . . . 3779
9.7.2.2.2 Viscous force on a fluid element . . . 3782
9.7.2.3 Bernoulli's Theorem . . . 3783
9.7.2.3.1 Torricelli's barometer . . . 3791
9.7.2.3.2 Torricelli's law . . . 3793
9.7.2.3.3 Siphon . . . 3798

9.7.2.4.1 Incompressible flow . . . 3828
9.7.2.4.1.1 Vorticity and vorticity equation . . . 3836
9.7.2.4.1.2 Circulation . . . 3845
9.7.2.4.2 Compressible flow . . . 3846
9.7.2.4.3 Static flow . . . 3846
9.7.2.4.4 Reynolds number . . . 3847
9.7.2.4.5 Boussinesq approximation (buoyancy) . . . 3851
9.7.2.4.6 Stokes' law . . . 3853
9.7.2.4.6.1 Why don't clouds fall? . . . 3861
9.7.2.4.7 Betz's law . . . 3862
9.7.2.4.7.1 Wind pressure . . . 3867
9.7.2.5 Levelling law . . . 3869
9.7.2.6 Hydrostatic Pressure . . . 3872
9.7.2.7 Archimedes' principle . . . 3875
9.7.2.8 Surface tension . . . 3882
9.7.2.9 Speed of sound in a liquid . . . 3885
9.7.2.10 Summary of fluid dynamics laws . . . 3886
9.7.3 Gas . . . 3888
9.7.3.1 Types of Gas . . . 3888
9.7.3.1.1 Perfect Gas . . . 3888
9.7.3.1.2 Real Gas . . . 3897
9.7.3.2 Virial Theorem . . . 3897
9.7.3.2.1 Equipartition theorem of energy derivation based on quantum physics and statistical mechanics . . . 3911
9.7.3.3 Kinetic Pressures (kinetic theory of gases) . . . 3918
9.7.3.4 Kinetic Temperature . . . 3921
9.7.3.5 Amagat and Dalton's law . . . 3924
9.7.3.6 Mean free path (in kinetic theory) . . . 3925
9.7.3.7 Sackur-Tetrode equation . . . 3931
9.7.3.7.1 Case for distinguishable particles . . . 3931
9.7.3.7.2 Case for indistinguishable particles . . . 3933
9.7.3.8 Generalized Bernoulli equation (for gases) . . . 3936
9.7.3.9 Magnus (gravitational) Effect . . . 3938
9.7.3.9.1 Naive approach for the spherical and cylinder rotating case . . . 3939

9.7.3.10 Summary of gas laws . . . 3943
9.7.4 Plasmas . . . 3945
9.7.4.1 Plasma Frequency . . . 3947
9.7.4.2 Lawson Criterion for D-T . . . 3951
9.7.4.3 Saha ionization equation . . . 3954
9.7.4.4 Ionospheric propagation . . . 3958

10 Electromagnetism 3964

10.1 Electrostatics . . . 3968
10.1.1 Electric Force . . . 3969
10.1.2 Electric Potential . . . 3976
10.1.2.1 Path Independence . . . 3979
10.1.3 Equipotential and Field lines . . . 3980
10.1.3.1 Infinite straight wire . . . 3982
10.1.3.2 Electric Rigid Dipole . . . 3984
10.1.4 Electric Flux . . . 3996
10.1.4.1 Capacitor . . . 3997
10.1.4.1.1 Dielectric strength . . . 4003
10.1.5 Electrostatic potential energy . . . 4005
10.2 Magnetostatics . . . 4008
10.2.1 Ampère's theorem . . . 4011
10.2.1.1 Infinitely long solenoid . . . 4014
10.2.1.2 Toroidal coils . . . 4018
10.2.1.3 Electromagnet . . . 4019
10.2.1.3.1 Strength of a magnet or electromagnet . . . 4020
10.2.2 Maxwell-Ampère Relation . . . 4022
10.2.3 Biot-Savart law . . . 4023
10.2.3.1 Magnetic field for a current loop . . . 4025
10.2.3.2 Magnetic field for an infinite wire . . . 4026
10.2.4 Magnetic dipole . . . 4030
10.2.4.1 Magnetic torque . . . 4050
10.2.5 Lorentz law (Lorentz force) . . . 4052
10.2.5.1 Magnetic Vector Potential . . . 4057
10.2.5.2 Work of Magnetic Field . . . 4062
10.2.5.3 Classical Hall effect . . . 4065
10.2.5.4 Larmor radius . . . 4068
10.2.5.5 Energy of a magnetic dipole . . . 4081
10.2.6 Langevin treatment of Diamagnetism and Paramagnetism . . . 4085
10.2.6.1 Langevin model of diamagnetism . . . 4085
10.2.6.2 Langevin model of paramagnetism . . . 4088
10.3 Electrodynamics . . . 4094
10.3.1 Maxwell Equations . . . 4095
10.3.1.1 First Maxwell Equation (constant electric flow) . . . 4095
10.3.1.2 Second Maxwell Equation (non-existence of magnetic monopole) . . . 4099
10.3.1.3 Third Maxwell Equation . . . 4101

10.3.1.3.1 Betatron . . . 4103
10.3.1.4 Fourth Maxwell Equation . . . 4106
10.3.1.5 Magnetic Monopoles . . . 4110
10.3.2 Charge conservation equation . . . 4114
10.3.3 Gauge Theory . . . 4115
10.3.3.1 Electromagnetic field tensor . . . 4121
10.3.4 Electromagnetic wave equation . . . 4138
10.3.4.1 Foucault light speed experiment . . . 4145
10.3.4.2 Helmholtz equation . . . 4152
10.3.4.3 Energy flow transportation (Poynting vector) . . . 4156
10.3.4.4 Emissions . . . 4160
10.3.5 Synchrotron radiation (bremsstrahlung) . . . 4163
10.3.5.1 Liénard-Wiechert potentials . . . 4168
10.3.5.2 Retarded Electric and Magnetic fields . . . 4175
10.3.5.3 Power radiated through an elementary surface . . . 4188
10.3.5.3.1 Larmor's equation (non-relativistic derivation) . . . 4198
10.3.5.3.2 Abraham-Lorentz force . . . 4201
10.3.6 Dipole antenna radiation pattern derivation (Hertz Electric Dipole) . . . 4203
10.3.6.1 The $L = \lambda/2$ (half-wave) far-field resonant antenna . . . 4214
10.4 Electrokinetics . . . 4219
10.4.1 Kirchhoff's laws . . . 4221
10.4.1.1 Mesh law (Kirchhoff's Loop Law) . . . 4221
10.4.1.2 Nodes law (Kirchhoff's Point Law) . . . 4222
10.4.2 Drude model . . . 4226
10.4.3 Ohm's law . . . 4233
10.4.3.1 Complex Conductivity . . . 4238
10.4.3.2 Simple (harmonic oscillator) model of dielectric and conductors (and plasmas) . . . 4240
10.4.3.2.1 Dielectrics . . . 4241
10.4.3.2.2 Conductors . . . 4244
10.4.3.3 Equivalent Resistance . . . 4246
10.4.3.4 Equivalent Capacities . . . 4248
10.4.3.5 Equivalent Inductance . . . 4250
10.4.4 Electromotive Force . . . 4253
10.4.4.1 Faraday's law of induction . . . 4258
10.4.4.1.1 Lenz's law . . . 4260
10.4.4.2 Inductance . . . 4261
10.4.5 Electromagnetic Waves in Conductors . . . 4268
10.4.5.1 Skin effect . . . 4268
10.4.5.2 Phase and group velocity of EM waves inside conductors (modified Maxwell equations) . . . 4272
10.4.6 Semiconductors . . . 4279
10.4.6.1 Non-degenerated statistic density of negative electric charge carriers . . . 4291
10.4.6.2 Non-degenerated statistic density of positive electric charge carriers . . . 4296
10.4.6.3 Energy bands (conduction band, band gap, valence band) . . . 4300
10.4.6.4 Ohm's law of Semiconductors . . . 4304
10.4.7 Superconductivity . . . 4307

10.4.7.1 Meissner effect (second London's equation) 4308
10.5 Optics (ray optics) 4314
10.5.1 Sources and Shadows 4315
10.5.2 Colors 4325
10.5.3 Radiometry/Photometry 4337
10.5.3.1 Energy flow 4337
10.5.3.1.1 Beer–Lambert law 4337
10.5.3.2 Light Intensity (Radiant Intensity) 4339
10.5.3.3 Energy Emittance (Radiant Emittance) 4340
10.5.3.4 Radiance and Luminance 4343
10.5.3.4.1 Lambert's law 4350
10.5.3.5 Kirchhoff's law of Radiation 4351
10.5.3.6 Spectral Decomposition 4352
10.5.4 Law of Refraction and Reflection 4353
10.5.4.1 Refractive index 4358
10.5.4.1.1 Index of refraction rate of change with altitude 4360
10.5.4.2 Snell's law 4364
10.5.4.3 Rainbow 4372
10.5.4.4 The 22° Halo 4385
10.5.4.5 Optical Mirages 4397
10.5.4.5.1 Lagrangian approach to optical mirage 4400
10.5.4.5.2 Snell's law differential approach to air mirroring 4403
10.5.4.5.3 Differential form of long range mirages 4410
10.5.4.6 Cherenkov radiation 4414
10.5.5 Descartes' Formulas 4416
10.5.5.1 Stigmatism 4420
10.5.5.2 Lenses 4426
10.5.5.2.1 Optical Magnification (zoom) 4441
10.5.5.2.2 Angle of View 4451
10.5.5.2.3 Human eyes 4458
10.5.5.2.3.1 Eye magnification 4459
10.5.5.3 Triangular Prism 4462
10.5.5.4 Pentaprism 4466
10.6 Wave Optics 4470
10.6.1 Huygens' principle 4470
10.6.1.1 Normal refraction 4479
10.6.1.2 Thin film interference 4481
10.6.1.3 Fresnel coefficients 4485
10.6.2 Fraunhofer Diffraction 4492
10.6.2.1 Case of a small rectangular aperture (slit) 4492
10.6.2.1.1 Optical resolution in the far field region for small rectangular aperture 4500
10.6.2.2 Case of a network of small rectangular apertures (slits) 4502
10.6.2.3 Young's interference experiment 4509
10.6.3 Fresnel diffraction 4517
10.6.3.1 Case of a rectangular aperture 4517

10.6.3.2 Case of a circular aperture . . . 4521
10.6.3.2.1 Optical resolution in the near field region for circular aperture . . . 4529
10.6.3.3 Case of a circular obstacle . . . 4536
10.6.4 Light polarization . . . 4538
10.6.4.1 Linear polarization . . . 4543
10.6.4.2 Elliptical polarization . . . 4544
10.6.4.3 Circular polarization . . . 4546
10.6.4.4 Natural polarization . . . 4547
10.6.4.5 Malus' law . . . 4550
10.6.5 Coherence and interference (interferometry) . . . 4554
10.6.5.1 Michelson Interferometer . . . 4562
10.6.5.1.1 Case of circular Haidinger fringes . . . 4568
10.6.5.1.2 Case of hyperbolic Haidinger fringes . . . 4569
10.6.5.1.3 Case of straight Haidinger fringes . . . 4573
10.6.5.1.4 Michelson interferometer and Special Relativity . . . 4577
10.6.5.2 Sagnac interferometer (Sagnac effect) . . . 4579
10.6.6 LASER . . . 4587
10.6.6.1 LASER Dispersion/Divergence . . . 4595
10.6.7 Fiber Optics . . . 4604

12.1.3.2 Second Kepler's Law (area law) . . . 5234
12.1.3.2.1 Acceleration variation on an elliptic orbit . . . 5237
12.1.3.2.2 Time of flight . . . 5238
12.1.3.3 Third Kepler's Law (periods' law) . . . 5242
12.1.4 Newton's Gravitational Law . . . 5255
12.1.4.1 Cavendish Experiment . . . 5270
12.1.4.2 Gaussian formulation of Newtonian Gravity . . . 5277
12.1.4.3 Shell Theorem . . . 5281
12.1.4.4 Orbital speed . . . 5282
12.1.4.5 Gravitational field of a homogeneous disc . . . 5284
12.1.4.6 Collision time of two objects at rest . . . 5295
12.1.4.7 Asteroids/Meteors impact velocity . . . 5297
12.1.4.8 Spherisation of Celestial Bodies . . . 5299
12.1.4.8.1 Flattening of Celestial Bodies (rotational flattening) . . . 5300
12.1.4.8.2 Empirical evidence that Earth isn't globally flat . . . 5314
12.1.4.9 Stability of Atmospheres . . . 5331
12.1.4.10 Planetary equilibrium temperature . . . 5335
12.1.5 Roche's Limit . . . 5337
12.1.6 Keplerian Orbitals . . . 5340
12.1.6.1 First Binet Formula (radial velocity) . . . 5340
12.1.6.2 Second Binet Formula (radial acceleration) . . . 5346
12.1.6.3 Keplerian orbital period . . . 5350
12.1.6.4 Average distance between two planets . . . 5356
12.1.6.5 Classical deflection of light (light bending) . . . 5358
12.1.6.6 Classical precession of perihelion (apsidal precession) . . . 5361
12.1.7 Duration of the diurnal arc . . . 5372
12.1.7.1 Evolution of diurnal arc (i.e. Earth-Moon distance) . . . 5379
12.1.8 Trigonometric parallax . . . 5383
12.1.9 Planets' Motion . . . 5388
12.1.9.1 Synodic and Sidereal period . . . 5390
12.1.9.2 Planet's apparent retrograde motion . . . 5395
12.1.10 Equation of Time and Analemma . . . 5404
12.1.10.1 Eccentricity component (variable angular velocity of Earth) . . . 5407
12.1.10.2 Obliquity (inclined plane of the ecliptic) and Sun anomaly . . . 5419
12.1.10.3 Calculation of the Equation of Time . . . 5423
12.1.11 Sundials . . . 5438
12.1.11.1 Equatorial sundials . . . 5441
12.1.11.2 Vertical sundials . . . 5443
12.1.11.3 Horizontal sundials . . . 5446
12.1.11.4 Anammelatic (azimuthal) sundials . . . 5449

12.1.12 Apparent solar time (true solar time) 5461
12.1.13 Celestial sphere and coordinate systems (positional astronomy) 5465
12.1.13.1 Local Sidereal Time 5467
12.1.13.2 Equatorial coordinates to Azimuthal (horizontal) coordinates 5472
12.1.13.3 Azimuthal (horizontal) coordinates to Equatorial coordinates 5474
12.1.13.4 Apparent daily path of the Sun (solargraph) 5476
12.1.14 Eclipses and saros cycles 5486
12.1.15 Lagrange Points 5498
12.1.15.1 Equilibrium points of the first type 5509
12.1.15.1.1 L1 Lagrange point 5509
12.1.15.1.2 L2 Lagrange point 5514
12.1.15.1.3 L3 Lagrange point 5517
12.1.15.2 Equilibrium points of the second type 5519
12.1.15.2.1 L4, L5 Lagrange points 5519
12.1.15.3 Hill sphere (sphere of influence) 5525
12.1.16 Relativistic Doppler-Fizeau Effect 5529
12.1.16.1 Apparent speed 5536
12.2 Astrophysics 5539
12.2.1 Stars 5539
12.2.1.1 Stellar Physics 5549
12.2.1.1.1 Collapse of an Interstellar Cloud 5549
12.2.1.1.1.1 Limit Mass Cloud for Ionization (rogue planets) 5552
12.2.1.1.1.2 Limit Mass Cloud for Fusion (Black Dwarf) 5553
12.2.1.1.1.3 Entropy of a gas collapsing under gravity 5555
12.2.1.1.2 Nuclear Duration Life 5558
12.2.1.1.3 Internal Temperature 5562
12.2.1.1.4 External Temperature 5566
12.2.1.1.5 Equation of Hydrostatic Equilibrium 5573
12.2.1.1.6 Brightness 5576
12.2.1.1.7 Shining (apparent brightness) 5577
12.2.1.1.8 Apparent magnitude 5580
12.2.1.1.9 Absolute magnitude 5586
12.2.1.1.9.1 Why are stars not visible on most space photos and videos 5591
12.2.1.1.10 Eddington limit 5597
12.2.1.2 Pulsative Variable Stars 5601
12.2.1.3 Neutron Stars (magnetars/pulsars) 5606
12.2.1.3.1 Chandrasekhar limit 5607
12.2.1.3.2 Rotation break limit 5612
12.2.1.3.3 Neutron Star Masses and Densities 5614
12.2.1.3.4 Neutron Star magnetic field 5615
12.2.1.3.5 Spin-Down Luminosity 5616
12.2.2 Galaxies 5620
12.2.2.1 Probability of collisions in merging galaxies 5623
12.2.2.2 Radial Speed Anomaly 5625
12.3 Special Relativity 5627

12.3.1 Assumptions and Principles . . . 5628
12.3.1.1 Postulate of Invariance . . . 5629
12.3.1.2 Cosmological Principle . . . 5630
12.3.1.3 Special Relativity Principle . . . 5630
12.3.2 Lorentz Transformations/Boost . . . 5633
12.3.2.1 Displacement four-vector . . . 5637
12.3.2.1.1 Wave Equation Invariance . . . 5640
12.3.2.1.2 Hypergeometric interpretation . . . 5641
12.3.2.2 Velocity four-vector . . . 5642
12.3.2.3 Current four-vector . . . 5646
12.3.2.4 Acceleration four-vector . . . 5647
12.3.2.5 Relativistic sum of velocities . . . 5652
12.3.2.6 Relativistic lengths variation (length contraction) . . . 5654
12.3.2.7 Relativistic apparent angle rotation (Lampa–Terrell–Penrose effect) . . . 5657
12.3.2.8 Relativistic time variation (time dilatation) . . . 5659
12.3.2.8.1 Lewis Carrol Epstein interpretation . . . 5662
12.3.2.8.2 Hafele–Keating experiment (special relativity version) . . . 5664
12.3.2.8.3 Twins paradox . . . 5669
12.3.2.9 Apparent relativistic mass . . . 5670
12.3.2.9.1 Why is Gold yellow? . . . 5675
12.3.2.9.2 Mass–Energy equivalence . . . 5679
12.3.2.9.3 Relativistic Lagrangian . . . 5681
12.3.2.9.4 Relativistic (linear) momentum . . . 5684
12.3.2.9.4.1 Einstein relation . . . 5688
12.3.2.9.4.2 Time of flight . . . 5689
12.3.2.9.4.3 Relativistic force . . . 5691
12.3.2.10 Relativistic electrodynamics . . . 5694
12.3.2.10.1 Tensor field transformation . . . 5702
12.3.3 Minkowski space-time . . . 5703
12.3.3.1 Four-vectors . . . 5706
12.3.3.2 Universe light cone . . . 5707
12.3.4 Empirical evidence of Special Relativity theory . . . 5716
12.4 General Relativity . . . 5720
12.4.1 Assumptions and Principles . . . 5721
12.4.1.1 Equivalence Postulates . . . 5721
12.4.1.2 Mach Principle . . . 5725
12.4.2 Metrics . . . 5728
12.4.2.1 Schild Criteria (Einstein redshift effect Newtonian approach) . . . 5735
12.4.3 Equations of movement . . . 5738
12.4.3.1 Geodesic equations . . . 5747
12.4.3.2 Newtonian Limit . . . 5751
12.4.4 Stress-Energy Tensor . . . 5754
12.4.4.1 Stress-Energy Tensor for a perfect fluid . . . 5762
12.4.4.2 Electromagnetic stress–energy tensor . . . 5763
12.4.5 Einstein’s Field Equations . . . 5766

12.4.5.1 Cosmological Constant (CC) 5774
12.4.5.2 Weak field approximation with cosmological constant 5778
12.4.5.3 Einstein-Maxwell equations 5780
12.4.5.4 Schwarzschild Solution 5781
12.4.6 Empirical evidence of General Relativity theory 5795
12.4.6.1 Gravitational Redshift 5796
12.4.6.2 Precession of Mercury's Perihelion 5800
12.4.6.3 Deflection of Light (light bending) 5812
12.4.6.4 Shapiro Effect (delay) 5821
12.4.6.5 Hafele–Keating experiment (general relativity version) 5827
12.4.6.6 Black Holes 5835
12.4.6.6.1 Schwarzschild Black Holes 5836
12.4.6.6.1.1 Black Hole innermost stable circular orbit 5840
12.4.6.6.1.2 Black Hole photon sphere 5853
12.4.6.6.1.3 Black Hole free fall proper time to singularity 5855
12.4.6.6.1.4 Black Hole Flamm's paraboloid representation 5858
12.4.6.6.1.5 White Hole 5860
12.4.6.7 Gravitational waves 5861
12.4.7 Einstein-Hilbert action 5869
12.4.7.1 Einstein-Hilbert action with cosmological constant 5875
12.4.7.2 Einstein-Hilbert action with matter 5876
12.5 Cosmogony 5878
12.5.1 Newtonian (i.e. non-relativistic) Cosmological Models 5881
12.5.1.1 Hubble's Law 5884
12.5.2 Friedmann Equations (Newtonian derivation) 5892
12.5.2.1 Critical Density and Density parameters 5897
12.5.3 Friedmann-Lemaître Euclidean Cosmological Models 5905
12.5.3.1 Flat spaces ($k = 0$) 5905
12.5.3.1.1 Flat space dominated by matter 5907
12.5.3.1.2 Flat space dominated by radiation 5908
12.5.3.1.2.1 Standard form of the Friedmann equation 5911
12.5.3.1.3 Flat space dominated by vacuum 5918
12.5.3.2 Spherical spaces ($k > 0$) 5920
12.5.3.2.1 Spherical space dominated by matter 5927
12.5.3.2.2 Spherical space dominated by radiation 5930
12.5.3.2.3 Spherical space dominated by vacuum 5932
12.5.3.3 Hyperbolic spaces ($k < 0$) 5934
12.5.3.3.1 Hyperbolic space dominated by matter 5938
12.5.3.3.2 Hyperbolic space dominated by radiation 5941
12.5.3.3.3 Hyperbolic space dominated by vacuum 5944
12.5.4 Observable Universe 5946
12.5.5 Cosmic Microwave Background (CMB) 5966
12.5.5.1 Decoupling time 5968
12.5.5.2 Matter/Photon decoupling (recombination temperature) 5973
12.5.5.3 Background radiation temperature 5984

12.5.6 Friedmann-Lemaître-Robertson-Walker Cosmological Models . . . 5987
  12.5.6.1 Robertson-Walker metric . . . 5987
  12.5.6.2 Cosmological Redshift . . . 5994
  12.5.6.3 Comobile Universe Diameter . . . 5998
  12.5.6.4 Size of the Universe depending on its curvature . . . 6000
  12.5.6.5 General Friedmann equations . . . 6004
  12.5.6.6 Einstein (static) Universe model . . . 6012
  12.5.6.7 Milne linear Universe model . . . 6013
  12.5.6.8 Friedmann Universe models . . . 6014
12.5.7 Friedmann historical derivation . . . 6050
12.5.8 The Black Hole Universe . . . 6058
12.5.9 Borde-Guth-Vilenkin Theorem (BGV Theorem) . . . 6061
12.5.10 Empirical evidence of the Cosmic Inflation theory (i.e. Big Bang) . . . 6069
12.6 Quantum Gravity/Cosmology . . . 6073
12.6.1 Newton Quantum Gravity . . . 6074
12.6.2 Wheeler-DeWitt Quantum Cosmology . . . 6083
  12.6.2.1 Wheeler-DeWitt equation for Newtonian Universe . . . 6085
  12.6.2.2 Wheeler-DeWitt equation for FLRW Universe . . . 6090
12.6.3 Why our Universe is a quite massive unpredictable mess . . . 6097
12.7 String Theory . . . 6099
12.7.1 Wave equation of a transversal string . . . 6101
12.7.2 Non-relativistic Wave equation of a transversal string . . . 6104
  12.7.2.1 Nambu-Goto Action . . . 6109
12.7.3 Lagrangian of a String . . . 6117

13 Chemistry 6122

13.1 Quantum Chemistry . . . 6123
13.1.1 Infinite three-dimensional rectangular potential . . . 6125
13.1.2 Molecular Vibrations . . . 6128
13.1.3 Hydrogenoid Atom (Schrödinger model) . . . 6130
  13.1.3.1 Rigid Rotator . . . 6134
  13.1.3.2 Non-Rigid Rotator . . . 6173
    13.1.3.2.1 Potential Profile . . . 6187
13.2 Molecular Chemistry . . . 6190
13.2.1 Orbital Approximations . . . 6192
13.2.2 LCAO Method . . . 6196
13.2.3 Molecular Rotational Energy Levels . . . 6205
13.2.4 Molecular Vibrational Energy Levels . . . 6211
13.2.5 Morse potential . . . 6216
13.3 Analytical Chemistry . . . 6228
13.3.1 Analytical chemistry process . . . 6234
13.3.2 Simple Mixtures . . . 6235
13.3.3 Chemical formula . . . 6237
13.3.4 Reactions . . . 6241
13.4 Thermochemistry . . . 6249

13.4.1 Chemical transformations . . . 6249
13.4.2 Molar Quantities . . . 6252
13.4.2.1 Standard enthalpy of reaction . . . 6259
13.4.2.1.1 Kirchhoff's Enthalpy Law . . . 6262

14 Theoretical Computing 6267

14.1 Numerical Methods/Analysis . . . 6272
14.1.1 Computer Representation of Numbers . . . 6274
14.1.1.1 Decimal System . . . 6274
14.1.1.2 Binary system . . . 6275
14.1.1.2.1 Floating Point (Real Numbers) . . . 6277
14.1.1.2.2 Binary arithmetic (for fixed point/integers) . . . 6279
14.1.1.3 Hexadecimal System . . . 6280
14.1.1.4 Octal System . . . 6280
14.1.1.5 Conversion of decimal system to non-decimal system: . . . 6282
14.1.2 Algorithm Complexity . . . 6284
14.1.2.1 NP-Completude . . . 6291
14.1.3 Integer Part . . . 6293
14.1.4 Heron's Square Root Algorithm . . . 6295
14.1.5 Archimedes Algorithm . . . 6298
14.1.6 Euler's Number e . . . 6301
14.1.7 Stirling's factorial approximation . . . 6301
14.1.8 Linear Systems of Equations . . . 6304
14.1.8.1 One equation with one unknown . . . 6304
14.1.8.2 Two equations with two unknowns . . . 6304
14.1.8.3 Three equations with three unknowns . . . 6306
14.1.8.4 n equations with n unknowns . . . 6310
14.1.9 Polynomials . . . 6312
14.1.10 Regression Techniques . . . 6316
14.1.10.1 Univariate linear regression model . . . 6322
14.1.10.1.1 Regression line . . . 6323
14.1.10.1.2 Ordinary Least Squares Method (OLSM) . . . 6324
14.1.10.1.3 Univariate Regression Variance Analysis . . . 6329
14.1.10.1.4 F-test for Regression (significance test for linear regression) . . . 6335
14.1.10.1.4.1 Test for Lack of Fit . . . 6345
14.1.10.2 Univariate linear regression Gaussian Model . . . 6348
14.1.10.2.1 Pearson Correlation Coefficient Test . . . 6358
14.1.10.2.2 Confidence interval of predicted values . . . 6361
14.1.10.3 Linear univariate regression forced through the origin (RTO) . . . 6369
14.1.10.4 Deming regression (orthogonal regression) . . . 6372
14.1.10.4.1 Deming orthogonal regression log-likelihood derivation . . . 6372
14.1.11 Multiple linear regression Gaussian Model . . . 6379
14.1.11.1 Fisher Matrix . . . 6389
14.1.11.2 R^2 decomposition in multiple regression . . . 6390
14.1.11.3 Influential points . . . 6391

14.1.11.4 Significance of regression coefficients (variable importance) . . . 6395
14.1.11.5 Variance Inflation Factor (multicollinearity detection) . . . 6398
14.1.11.5.1 Gauss-Markov theorem . . . 6405
14.1.11.6 Weighted Least Squares (WLS) . . . 6407
14.1.11.7 Model Selection Criteria . . . 6412
14.1.11.7.1 Mallows's C_p Linear Regression Prediction . . . 6413
14.1.11.7.2 Akaike Information Criterion (AIC) . . . 6418
14.1.11.7.3 Cross-Validation metrics . . . 6428
14.1.12 Ridge, LASSO and Elastic Net regularization . . . 6435
14.1.12.1 L_2 Regularization or Ridge Regularization . . . 6437
14.1.12.2 L_1 Regularization or LASSO Regularization . . . 6441
14.1.12.3 $L_1 + L_2$ Regularization or Elastic Net Regularization . . . 6443
14.1.12.4 Polynomial regression . . . 6445
14.1.12.5 Kernel regression . . . 6447
14.1.12.6 Logistic regressions (LOGIT) . . . 6449
14.1.12.6.1 Binomial Logistic regression . . . 6450
14.1.12.6.1.1 Binomial Logistic regression relative variable importance . . . 6465
14.1.12.6.1.2 Binomial logistic regression residuals . . . 6466
14.1.12.6.1.3 Hosmer–Lemeshow test . . . 6468
14.1.12.6.1.4 Logistic Kolmogorov-Smirnov statistic . . . 6470
14.1.12.6.1.5 Equivalence between the 2-sample Wald's Z-test and the Rao score test over logistic regression with a single binary predictor . . . 6471
14.1.12.6.2 Multinomial Logistic regression . . . 6477
14.1.12.6.2.1 F_1 score . . . 6482
14.1.12.6.3 Ordinal Logistic regression . . . 6487
14.1.12.6.4 Log-Loss . . . 6494
14.1.12.6.5 Odds Ratio Confidence Interval . . . 6496
14.1.12.6.5.1 Four-fold plot . . . 6501
14.1.12.6.6 Risk Ratio and its Confidence Interval . . . 6503

14.1.17.2.4 Gauss-Newton method's (Tangent Newton) . . . 6678
14.1.17.2.4.1 Gradient Descent/Ascent techniques summary . . . 6691
14.1.17.3 Expectation-Maximization (EM) algorithm . . . 6697
14.1.18 Resampling statistics . . . 6707
14.1.18.1 Monte Carlo Simulations . . . 6708
14.1.18.1.1 Inverse Transform Sampling . . . 6710
14.1.18.1.2 Random number generation . . . 6713
14.1.18.1.3 Monte Carlo integration . . . 6717
14.1.18.1.4 Monte Carlo estimation of π . . . 6721
14.1.18.1.5 Monte Carlo Modelling . . . 6723
14.1.18.1.6 Monte Carlo variance reduction . . . 6727
14.1.18.1.6.1 Method of Antithetic Variables . . . 6729
14.1.18.1.6.2 Method of Control Variables . . . 6730
14.1.18.1.6.3 Method of Conditioning . . . 6731
14.1.18.1.6.4 Method of Stratified Sampling . . . 6733
14.1.18.1.6.5 Importance Sampling (IS) . . . 6737

14.1.18.2 Bootstrapping . . . 6740
14.1.18.3 Jackknife Resampling . . . 6747
14.1.18.4 Permutation Tests . . . 6749
14.1.19 Finite difference method (F.D.M.) . . . 6752
14.1.19.1 One space dimension F.D.M. . . . 6753
14.1.19.1.1 Numerical instability . . . 6756
14.1.19.1.2 von Neumann stability . . . 6757
14.1.19.2 Space-time F.D.M (finite-volume method) . . . 6759
14.1.20 Data Science & Data Mining . . . 6768
14.1.20.1 Training vs Test Data . . . 6795
14.1.20.2 Hyperparameters vs Parameters . . . 6803
14.1.20.3 Association Rules . . . 6808
14.1.20.3.1 ZeroR . . . 6809
14.1.20.3.2 OneR (classification by induction) . . . 6810
14.1.20.3.3 Apriori . . . 6814
14.1.20.4 Equivalence CLAss Transformation (ECLAT) . . . 6820
14.1.20.5 Clustering and Classification . . . 6822
14.1.20.5.1 Naive Bayes classifiers . . . 6826
14.1.20.5.1.1 Binomial Naive Bayes classifier . . . 6826
14.1.20.5.1.2 Gaussian Naive Bayes classifier . . . 6830
14.1.20.5.2 k-nearest neighbours classifier (k-nn) . . . 6832
14.1.20.5.3 Regression and classification trees . . . 6835
14.1.20.5.3.1 Binary classification trees with quantitative variables . . . 6836
14.1.20.5.3.2 Detection of significant splits . . . 6846
14.1.20.5.3.3 Classification (and clustering) validation . . . 6847
14.1.20.5.3.4 Random Forests . . . 6852
14.1.20.5.4 k-means clustering . . . 6854
14.1.20.5.5 Support Vector Machines (SVM) classifier . . . 6867
14.1.20.5.6 Gaussian Mixture Model (GMM) clustering . . . 6874
14.1.20.5.7 Density-Based Spatial Clustering of Applications with Noise (DBSCAN) . . . 6883
14.1.20.5.8 Mean shift clustering . . . 6888
14.1.20.5.9 Hierarchical Ascendant Clustering (HAC) . . . 6896
14.1.20.5.10 Linear Discriminant Analysis . . . 6908
14.1.20.5.10.1 Two classes problem . . . 6909
14.1.20.5.10.2 Multiclass problem . . . 6916
14.1.20.6 Dimensionality Reduction . . . 6918
14.1.20.6.1 Principal Component Analysis . . . 6919
14.1.20.6.2 Linear Discriminant Analysis (LDA) . . . 6919
14.1.20.6.3 MultiDimensional Scaling (MDS) . . . 6920
14.1.20.6.3.1 Classical MDS (cMDS) . . . 6921
14.1.20.6.4 Factor Analysis (Exploratory Factor Analysis (EFA)) . . . 6925
14.1.20.6.4.1 Expectation-Maximization (EM) algorithm solution . . . 6932
14.1.20.6.4.2 Principal Factor Analysis Extraction solution . . . 6935
14.1.20.6.5 T-distributed Stochastic Neighbor Embedding (T-SNE) . . . 6939
14.1.20.6.5.1 KL gradient of Stochastic Neighbour Embedding (SNE) . . . 6942

14.1.20.6.5.2 KL gradient of T-distributed Stochastic Neighbour Embedding (T-SNE) . . . 6943
14.1.20.7 Gradient Boosting . . . 6945
14.1.20.8 Neural networks . . . 6951

15.3.13.3.2 Linear Model With Seasonal Coefficients (LMSC) 7922

15.3.13.3.3 Exponential Smoothing models . . . 7927
15.3.13.3.3.1 Simple Exponential Smoothing (EWMA) . . . 7928
15.3.13.3.3.2 Double Exponential Smoothing with One Parameter (Brown Method) . . . 7937
15.3.13.3.3.3 Holt's Double Exponential Smoothing with 2 Parameters (Additive Method) . . . 7945
15.3.13.3.3.4 Holt's and Winter Triple Exponential Smoothing with 3 Parameters (Multiplicative Method) . . . 7951
15.3.13.3.3.5 ETS (Error, Trend, Seasonality) Models . . . 7958
15.3.13.3.4 Logistic Model . . . 7965
15.3.13.4 Autoregressive Models . . . 7972
15.3.13.4.1 AR(p) Autoregressive processes . . . 7983
15.3.13.4.2 MA(q) Moving Average stationary process . . . 7986
15.3.13.4.3 ARMA(p, q) Autoregressive non-seasonal moving average processes . . . 7988
15.3.13.4.4 ARIMA(p, d, q) Autoregressive non-seasonal integrated moving average processes . . . 7989
15.3.13.4.5 ARCH-GARCH processes . . . 7999
15.3.13.4.5.1 ARCH (Autoregressive Conditional Heteroskedasticity) . . . 8000
15.3.13.4.5.2 GARCH (Generalized Autoregressive Conditional Heteroskedasticity) . . . 8004
15.3.13.5 Forecasting Stationary Processes . . . 8005
15.3.13.5.1 Linear Minimal Mean Square Estimation (LMMSE) . . . 8010
15.3.13.6 TBATS . . . 8012
15.3.13.7 Recipes for modelling time series data . . . 8013
15.3.13.7.1 Durbin-Watson autocorrelation test . . . 8015
15.4 Quantitative Management . . . 8021
15.4.1 Corporate and Government Finance Management . . . 8024
15.4.1.1 Basic Accounting Equation . . . 8026
15.4.1.2 Ratio Analysis . . . 8027
15.4.1.2.1 Short term solvency or liquidity measure . . . 8029
15.4.1.2.2 Long term solvency or Liquidity measure . . . 8030
15.4.1.2.3 Profitability Measures . . . 8031
15.4.1.2.4 Growth Rate . . . 8032
15.4.1.2.5 Asset management or turnovers measures . . . 8033
15.4.1.2.6 Market Value Measures . . . 8033
15.4.1.2.7 Data Envelopment Analysis . . . 8034
15.4.1.3 Weighted Average Cost of Capital (WACC) . . . 8044
15.4.1.4 Break-even Point Analysis (BEPA) . . . 8047
15.4.1.5 Investment Strategies . . . 8049
15.4.1.5.1 Net Present Value . . . 8050
15.4.1.5.2 Internal Rate of Return . . . 8057
15.4.1.5.3 Payback . . . 8059
15.4.1.6 Company Valuation Methods . . . 8060
15.4.1.6.1 Balance sheets-based method . . . 8062
15.4.1.6.1.1 Book Value . . . 8062
15.4.1.6.1.2 Adjusted Book Value . . . 8063
15.4.1.6.1.3 Liquidation Value . . . 8064
15.4.1.6.1.4 Substantial Value . . . 8064
15.4.1.6.1.5 Book Value and Market Value . . . 8065
15.4.1.6.2 Income Statemented-Based Methods . . . 8065

15.4.1.6.2.1 Value of Earnings with PER 8066
15.4.1.6.2.2 Value of Dividends 8067
15.4.1.6.2.3 Sales Multiples 8069
15.4.1.6.3 Goodwill-Based Methods 8069
15.4.1.7 Capital Goods 8070
15.4.1.7.1 Linear Amortization 8070
15.4.1.7.2 Arithmetic Declining Amortization 8071
15.4.1.7.3 Geometric Declining Amortization (declining balance) 8072
15.4.2 Project Management 8074
15.4.2.1 Probabilistic PERT (Beta-PERT Distribution) 8074
15.4.2.2 Project planning variance reduction 8083
15.4.2.3 Process Reliability 8086
15.4.2.4 Divide and rule? 8088
15.4.3 Lean Management (Six Sigma Process) 8092
15.4.3.1 Pareto Analysis 8095
15.4.3.1.1 Gini Index 8099
15.4.3.2 Weighted Ishikawa Diagram 8102
15.4.4 Supply Chain Management 8106
15.4.4.1 Supply Chain Management in uncertain future 8108
15.4.4.1.1 Safety Stock formula 8110
15.4.4.2 Optimal initial stock management with zero rotation 8112
15.4.4.3 Wilson's Models 8119
15.4.4.3.1 Wilson's model with resupply 8124
15.4.4.3.2 Wilson's model without resupply 8133
15.4.4.3.3 Wilson's model with resupply and break-up 8136
15.4.5 Queueing Theory 8141
15.4.5.1 $M/M/\ldots$ arrival times modelisation 8145
15.4.5.2 $M/M/\ldots$ service times modelisation 8150
15.4.5.3 Kendall queues notation 8152
15.4.5.4 Modelling of arrivals and departures $M/M/1$ 8154
15.4.5.5 Probability of standby in a $M/M/k/k$ queue (Erlang-B formula) 8162
15.4.5.6 Probability $M/M/K/+\infty$ of standby (Erlang-C formula) 8165
15.4.6 Insurance 8170
15.4.6.1 Premium pricing 8172
15.4.6.2 Taking account of the return on experience 8175
15.4.6.3 Discounting factor of a retirement insurance 8177
15.4.6.4 Pension insurance (life annuities) 8180
15.4.6.4.1 Temporary life annuity 8181
15.4.6.4.2 Deferred life annuity 8183
15.4.7 Sensitivity Analysis 8184
15.4.7.1 Direct Bias Method 8186
15.4.7.2 Correlation Method 8190
15.5 Music Mathematics (physics of hearing) 8195
15.5.1 Longitudinal Sound Waves 8195
15.5.1.1 Power carried by a sound wave 8203

15.5.1.2 Measuring the intensity of a sound . . . 8207
15.5.2 Spherical Sound Waves . . . 8210
15.5.3 Doppler effect . . . 8212
15.5.3.1 Fixed source-Moving observer . . . 8214
15.5.3.2 Moving source-Fixed observer . . . 8215
15.5.3.3 Moving source and observer . . . 8217
15.5.4 Shock waves . . . 8218
15.5.5 Music Scales . . . 8220
15.5.6 Harmonic Oscillator . . . 8224
15.5.6.1 Damping and Resonance . . . 8227

16 Engineering 8234

16.1 Marine & Weather Engineering . . . 8239
16.1.1 Visual horizon . . . 8244
16.1.1.1 Discerning the curvature of the Earth . . . 8257
16.1.2 Wind direction . . . 8261
16.1.3 Atmospheric Profile Models . . . 8264
16.1.3.1 Atmospheric Exponential Profile Model . . . 8264
16.1.3.2 Adiabatic Atmosphere Model . . . 8268
16.1.3.2.1 Hypsometric equation . . . 8271
16.1.4 Earth’s equilibrium temperature . . . 8272
16.1.4.1 Greenhouse effect . . . 8275
16.1.4.2 Milankovitch cycles . . . 8276
16.1.5 Temperature variation range models . . . 8278
16.1.5.1 Diurnal temperature range (DTR) . . . 8278
16.1.5.2 Seasonal temperature range (STR) . . . 8281
16.1.6 Weather (sounding) balloon . . . 8288
16.1.7 Cyclogenesis and Anticyclogenesis . . . 8291
16.1.8 Tides . . . 8301
16.1.8.1 Astronomical tides (influence Moon/Sun) . . . 8303
16.1.8.1.1 First approach (naive center of mass model) . . . 8304
16.1.8.1.2 Second approach (vector field model) . . . 8308
16.1.8.1.2.1 Tides hight . . . 8316
16.1.9 Lorenz equations . . . 8318
16.1.9.1 Rayleigh-Bénard convection cells (Benard-Marangoni instability) . . . 8328
16.1.9.2 Lorenz attractor and chaos . . . 8337
16.1.10 Waves . . . 8344
16.1.10.1 Depth of a wave . . . 8356
16.1.10.2 Wave’s amplitude . . . 8357
16.2 Mechanical Engineering . . . 8359
16.2.1 Mechanical Efficiency . . . 8360
16.2.2 Gears . . . 8362
16.2.2.1 Transmission ratios . . . 8365
16.2.2.2 Gears association . . . 8368
16.2.2.2.1 Odd/Even Gear "problem" . . . 8373

16.2.2.3 Types of Gears 8374
16.2.3 Strength of materials 8382
16.2.3.1 Quadratic moments 8385
16.2.3.2 Equation of the elastic line 8388
16.2.3.2.1 Euler-Bernoulli Beam equation 8394
16.2.3.2.2 Potential elastic energy 8403
16.2.3.3 Torsion 8404
16.2.3.4 Buckling 8408
16.2.3.4.1 Self-buckling 8415
16.2.3.5 Traction 8425
16.2.3.6 Pressure Vessels 8426
16.2.3.6.1 Thin cylinders subjected to internal pressure 8427
16.2.3.6.1.1 Hope stress σ_θ 8428
16.2.3.6.1.2 Longitudinal stress σ_L 8429
16.2.3.6.2 Thin sphere subjected to internal pressure 8431
16.2.3.7 Centrifugal expansion of a rotating ring 8434
16.3 Electrical Engineering 8437
16.3.1 Elementary primitive electrical symbols 8441
16.3.2 Alternative current VS Direct current 8444
16.3.2.1 DC generator (dynamo) 8447
16.3.2.2 Average power 8451
16.3.3 Transformers 8455
16.3.3.1 Transformer universal EMF equation 8461
16.3.4 Steady State Linear Circuits 8463
16.3.4.1 RC series circuit 8467
16.3.4.1.1 RC series step response 8467
16.3.4.1.2 RC series linear response 8471
16.3.4.2 RL series circuit 8472
16.3.4.3 Source-Free serial RLC circuit 8475
16.3.4.3.1 Critically damped response ($R^4 = 4L/C$) 8477
16.3.4.3.2 Overdamped (hypercritic) response ($R^2 > 4L/C$) 8478
16.3.4.3.3 Underdamped (decaying oscillation) response ($R^2 < 4L/C$) 8480
16.3.4.4 Telegrapher's Equations 8486
16.3.4.4.1 Thomson's law of squares of transmission lines (latency metallic cables) 8490
16.3.5 Linear Circuit (RLC) in Forced Regime 8497
16.3.5.1 Low-pass filter 8501
16.3.5.2 High-pass filter 8502
16.3.5.3 Integrator and differentiator 8504
16.3.6 Signal Processing 8506
16.3.6.1 Nyquist-Shannon Theorem (Nyquist sampling theorem) 8506
16.3.7 Semiconductor devices 8519
16.3.7.1 Diodes 8519
16.3.7.1.1 Ideal Diode Equation 8522
16.3.7.1.1.1 Carrier concentrations in pure semiconductors 8522
16.3.7.1.1.2 Carrier concentrations in doped crystals 8524

16.3.7.1.1.3 pn-junctions 8526
16.3.7.1.1.4 Forward-biased pn-junction 8529
16.3.7.2 Amplifiers 8536
16.4 Civil Engineering 8539
16.4.1 Static 8541
16.4.2 Pulleys 8542
16.4.2.1 Windlass 8551
16.4.3 Cornu spiral 8553
16.4.4 Overhead cable 8558
16.4.4.1 Free overhead cable (catenary) 8559
16.4.4.2 Charges overhead cable (suspended bridge) 8567
16.4.4.3 Very tense cable 8571
16.4.5 Falling chimney (naive approach) 8573
16.4.6 Dams 8579
16.4.6.1 Power extracted from a Dam 8582
16.4.7 Tuned Mass Damper 8587
16.5 Aerospace Engineering 8590
16.5.1 Airfoil Lift 8591
16.5.1.1 Newton's lift argument (skipping stone argument) 8593
16.5.1.2 Bernoulli's lift argument (equal time argument) 8594
16.5.1.3 Euler's lift argument 8596
16.5.1.4 Coandă lift argument 8600
16.5.1.5 Kutta-Joukowski lift argument 8601
16.5.2 Cosmic speeds 8603
16.5.3 Fundamental Equation of Propulsion (Tsiolkovsky rocket equation) 8606
16.5.4 Geostationary orbit 8615
16.5.5 Vis-Viva equation 8619
16.5.6 Gravity assist 8622
16.5.6.1 Speed variation (in solar reference frame) 8623
16.5.6.2 Approaching speed from infinity 8626
16.5.6.3 Velocity variation and impact factor 8627
16.5.7 Hohmann Transfer orbit 8633
16.6 Software Engineering 8637
16.6.1 Algorithm 8637
16.6.2 Dichotomic Search algorithm 8639
16.6.2.1 Bisection algorithm 8639
16.6.2.2 Binary search algorithm 8642
16.6.3 Tower of Hanoi algorithm 8644
16.6.4 Sorting algorithms 8650
16.6.4.1 Bubble sort 8650
16.6.4.2 QuickSort algorithm 8652
16.6.5 Dijkstra's algorithm 8654
16.6.6 Google PageRank algorithm 8662
16.6.6.1 Weighted Count 8664
16.6.6.2 Recursive counting 8665

16.6.6.3 Absorbing states . . . 8669
16.7 Industrial Engineering . . . 8673
16.7.1 Six Sigma . . . 8674
16.7.1.1 Quality Control . . . 8677
16.7.1.2 Defaults/Errors . . . 8678
16.7.1.3 Capability Indices . . . 8683
16.7.1.4 Quality Levels . . . 8697
16.7.2 Taguchi Model . . . 8710
16.7.3 Preventive Maintenance . . . 8716
16.7.3.1 Planned Obsolescence . . . 8717
16.7.3.2 Reliability Empirical Estimators . . . 8720
16.7.3.2.1 Average Failure Rate . . . 8734
16.7.3.3 Weibull Distribution . . . 8736
16.7.3.3.1 Two-parameter Weibull distribution linearisation . . . 8741
16.7.3.4 Topology of Systems . . . 8743
16.7.3.4.1 Fault Tree Analysis . . . 8755
16.7.3.4.2 Markov Chain Reliability Model . . . 8757
16.7.3.5 Maximum Likelihood for failure rate determination of samples . . . 8761
16.7.3.6 Kaplan-Meier Survival Rate . . . 8763
16.7.3.7 ABC Method . . . 8772
16.7.3.8 XYZ Method . . . 8777
16.7.4 Design of Experiments (DoE) . . . 8780
16.7.4.1 Two levels factorial Designs . . . 8794
16.7.4.1.1 Replicated Full Factorial Designs . . . 8800
16.7.4.1.2 Plackett-Burman Designs . . . 8807
16.7.4.1.3 Fractional Factorial Designs . . . 8813
16.7.4.2 General factorial Designs . . . 8823
16.7.4.3 Taguchi Designs and Nomenclature (robust designs) . . . 8837
16.7.4.3.1 Signal Factor . . . 8846
16.7.4.4 Response Surface Methodology (Box Domains) . . . 8848
16.7.4.4.1 Pure quadratic curvature test . . . 8850
16.7.4.4.2 Box-Wilson Central Composite Designs . . . 8853
16.7.4.4.2.1 Circumscribed Center Designs . . . 8856
16.7.4.4.2.2 Face Centered Designs . . . 8861
16.7.4.5 Optimal Designs . . . 8865
16.7.4.6 Mixture Design . . . 8874
16.7.4.6.1 Network mixture designs (simplex lattice designs) . . . 8878
16.7.4.6.2 Full Factorial Combined with Mixture Design-Crossed Design . . . 8893
16.7.4.7 General DoE diagnostic tools . . . 8896
16.7.4.7.1 Lenth's PSE Pareto Margin Error for unreplicated factorial designs . . . 8896
16.7.4.7.2 Pareto Margin Error for replicated factorial designs . . . 8899
16.7.4.7.3 Desirability . . . 8900
16.7.5 Quality Control on Reception (Lot Acceptance Sampling Plans) . . . 8904
16.7.5.1 Simple acceptance sampling plan by measurement for a unique tolerance with known standard deviation . . . 8908

16.7.5.1.1 Calculation of the parameters using the norm AF-X06-023 8915
16.7.5.2 Simple acceptance sampling plan by attribute 8918
16.7.5.2.1 Calculation of the parameters using the norm ISO 2859-1 8924
16.7.5.3 Double acceptance sampling plan by attribute 8926
16.7.5.4 Operating characteristic curve (OC) 8927
16.7.5.5 Average outgoing quality (AOQ) 8930
16.7.6 Quality Control Charts (CC) 8934
16.7.6.1 WECO's empirical rules 8938
16.7.6.2 Sample size and Sampling frequency for Control Charts 8940
16.7.6.3 Attributes Control Charts (qualitative CC) 8944
16.7.6.3.1 P Control Charts (binomial proportion CC) 8945
16.7.6.3.2 NP Control Charts (binomial counting CC) 8949
16.7.6.3.3 C Control Charts (Poisson counting CC) 8953
16.7.6.3.4 U Control Charts (normalized Poisson) 8957
16.7.6.3.5 Laney's p' and u' control charts 8961
16.7.6.4 Measurement Control Charts (quantitative CC) 8963
16.7.6.4.1 Individual measurement control chart with required limits 8964
16.7.6.4.2 Individual measurement control chart with moving limits 8966
16.7.6.4.3 Subgroups measurement control chart with standard error 8972
16.7.6.4.4 $\overline{S}-S$ Subgroups measurement control chart for standard deviation 8977
16.7.6.4.5 $\overline{X}-S$ Subgroups measurement control chart 8986
16.7.6.4.6 $\overline{X}-S_P$ Subgroups measurement control chart with pooled variance 8991
16.7.6.4.7 $\overline{R}-R$ Subgroups measurement control chart 8996
16.7.6.4.8 $\overline{X}-R$ Subgroups measurement control chart 9001
16.7.6.5 Autocorrelated Measurement Control Charts (time weighted control charts) 9007
16.7.6.5.1 $\mathrm{I}-\mathrm{MR}/\overline{X}$ Individual moving range measurement control chart 9007
16.7.6.5.2 $\mathrm{I}-\mathrm{MR}/\overline{\mathrm{MR}}$ Individual moving range measurement control chart 9011
16.7.6.5.3 Individual Moving Average control chart 9014
16.7.6.5.4 CUSUM (cumulated sum) control chart with empirical V-mask 9019
16.7.6.5.5 EWMA control charts (exponential weighted moving average) with fixed limits 9026
16.7.6.6 Rare events control charts 9034
16.7.6.6.1 Frequency T control chart with probabilistic limits 9035
16.7.6.6.2 Frequency G control chart of rare events 9040
16.7.6.7 Control Charts Operating Characteristic (OC) Curves 9045
16.7.6.7.1 OC for $\bar{X}$ measurement control charts 9045
16.7.6.7.2 OC for P-type attribute control charts 9047
16.7.7 Design of reliability tests 9049
16.7.7.1 Chi-squared time of test 9050
16.7.7.2 Binomial sampling size 9053
16.7.7.3 Test to demonstrate MTBF (or MTTF) 9057
16.7.7.4 Beta-binomial sampling size 9059

2.1.1 Use of content

The contents of this textbook are elaborated by a development process by which volunteers reach a consensus. This process that brings together volunteers, research also the point of view of people interested in the topics of this textbook. The person in charge of this textbook administers the process and establishes rules to promote fairness in the consensus approach. It is also responsible for drafting the text, sometime for testing/evaluating or independently verifying the accuracy or completeness of the presented information.

We decline no responsibility for any injury, damage or any other kind, special, incidental, consequential or compensatory, arising from the publication, application or reliance on the content of this textbook. We make no express or implied warranty on the accuracy or completeness of any information published in this textbook, and do not guarantee that the information contained in this textbook meet any specific need or goal of the reader. We do not guarantee the performance of products or services of one manufacturer or vendor solely by virtue of this textbook content.

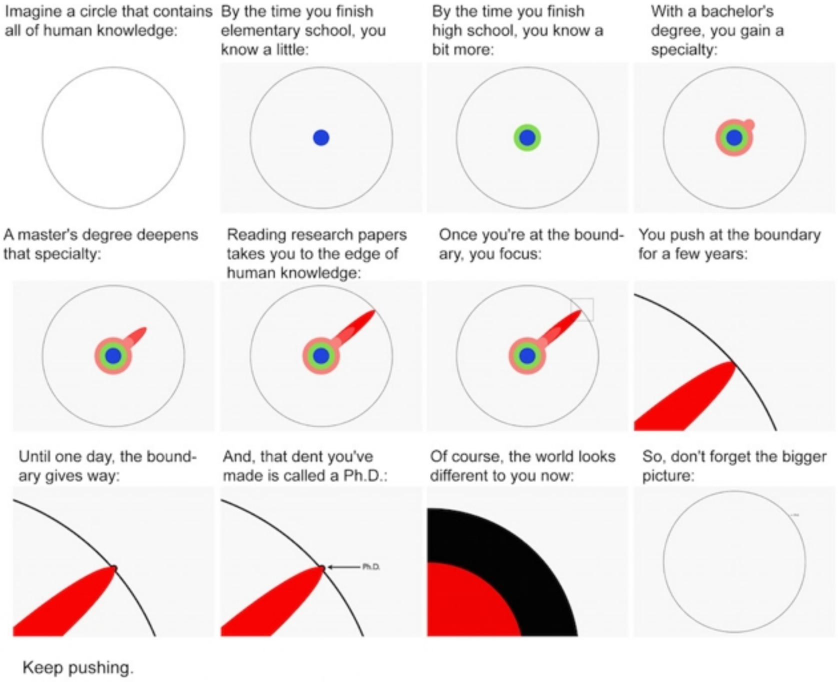
The technical descriptions, procedures, and computer programs in this textbook have been developed without care, therefore they are provide without warranty of any kind. We make also no warranties that the equations, programs, and procedures in this textbook or its associated software are free of error, or are consistent with any particular standard of merchantability, or will meet your requirements for any particular application. They should not be relied upon for solving a problem whose incorrect solution could result in injury to a person or loss of property. Any use of the content of this textbook as at the reader's own risk. The authors, redactors, and publisher disclaim all liability for direct, incidental, or consequent damages resulting form use of the content of this textbook or the associated software.

By publishing texts, it is not the intention of this textbook to provide services on behalf of any person or entity or performing any task to be accomplished by any person or entity for the benefit of a third party. Anyone using this textbook should rely on its own independent judgement or, where that is appropriate, seek the advice of a qualified expert to determine how to exercise reasonable care under all circumstances. The information and standards on the topics covered by this textbook may be available from other sources that the reader may wish to visit in search of points of view or additional information not covered by the contents of this textbook.

We have no power in order to enforce compliance with the contents of this textbook, and we do not undertake to monitor or enforce such compliance. We have no certification, testing or inspection activity of products, designs or installations for safety or health of persons and property. Any certification or other statement of compliance regarding information relating to health or safety of persons and property, mentioned in this textbook, cannot possibly be attributed to the content of this textbook and remains under the responsibility of the certification center or the concerned reporter.

2.1.2 How to use this textbook

At the university level, this textbook can be used for a PhD, graduate level or advanced undergraduate level seminar in various exact and pure fields of science. In reality this textbook also aims to cover the full Kindergarten to PhD curriculum.



Imagine a circle that contains all of human knowledge:
By the time you finish elementary school, you know a little:
By the time you finish high school, you know a bit more:
With a bachelor's degree, you gain a specialty:
A master's degree deepens that specialty:
Reading research papers takes you to the edge of human knowledge:
Once you're at the boundary, you focus:
You push at the boundary for a few years:
Until one day, the boundary gives way:
And, that dent you've made is called a Ph.D.:
Ph.D.
Of course, the world looks different to you now:
So, don't forget the bigger picture:
Keep pushing.

Figure 2.1: **Education and the bigger picture**

Because the methods of Applied Mathematics are learned by practice and experience, we view a seminar on Applied Mathematics as a learning-by-doing (project oriented) seminar. We structure our mathematical modelling seminars around a set of problems that require the trainee to construct models that help with planning and decision making. The imperative is that the models should be consistent with the theory and back-tested. To fulfil this imperative, it is necessary for the trainee to combine mathematical theory with modelling. The result is that the trainee learns the theory, and more importantly, learns how that theory is applied and combined in the real world. The ability to criticize and identify limitations of dangerous mathematical tools is the most valuable feature of our seminars.

quote 2.1:5.#2

> *Mathematics is not a deductive science - that's a cliché. When you try to prove a theorem, you don't just list the hypotheses, and then start to reason. What you do is trial and error, experimentation, guesswork. You want to find out what the facts are, and what you do is in that respect similar to what a laboratory technician does!*
>
> Paul Halmos

Remark

Mathematicians have always practised experimental mathematics. Existing records of early mathematics, such as Babylonian mathematics, typically consist of lists of numerical examples illustrating algebraic identities. However, modern mathematics, beginning in the 117th century (according to holocene calendar), developed a tradition of publishing results in a final, formal and abstract presentation. The numerical examples that may have led a mathematician to originally formulate a general theorem were not published, and were generally forgotten.

The problems with solutions in this textbook provide the opportunity to apply the text material to a comprehensive set of fairly realistic situations. By the end of the seminars the trainees will have enhanced their skills and knowledge of the most important theoretical and computing tools. These are valuable skills that are in demand by the businesses at the highest levels.

It is very difficult to cover all the material in this textbook in a semester. It takes a lot of time to explain the concepts to the trainees. The reader is encouraged to pick and choose which topics will be covered during the term. It is not necessary strictly necessary to cover them in sequence but it can help in a significant way?

In a nutshell, this textbook offers you a wide variety of topics that are amenable to modelling. All are practical.

2.1.2.1 Style guide

We use a few standard conventions throughout this textbook. They were prepared obviously with LaTeX which automatically numbers sections and the hyperref package provides links within the PDF for the Table of Contents as well as other references made within the body of the text.

We use color and some boxes to set apart some points for convenient reference. In particular:

- Clickable links and cross-references[1] are most of time in magenta (only a few special cases are in blue)
- Texts expliciting the target of cross-references are in light grey

---

[1] According to the Cambridge dictionary and to the scientific consensus a "cross-reference" is a note in a book or document that tells you to look somewhere else in the book or document for more information.

- New terms (most of time associated with definitions) are in red
- Remarks are in greyed out boxes
- Examples are in black bordered boxes
- Proofs start with the word "proof" and are concluded with a ■
- Supplementary examples[2] start with the symbol ✍

Doubtless, we have failed to live up to our legalism somewhere. If the reader keeps a list of these transgressions to give it to us at the end of the reading of this textbook would be very likely worthwhile for the redactors...

Caution!!! Any interpretation of the technical sections (i.e. of the mathematical proofs) in this textbook and related explanations in plain text has to be avoid (if we could we would even say that it is vorbidden!). The context is self-sufficient and therefore no words have other meaning, or implicit meaning, than the academic definition(s) that makes consensus at the time this textbook is published! All numbers are written in the decimal system and no prefix of the latter are implicitly hidden! There are also no hidden message in this textbook! The reader should focus only on the mathematical calculations and predictions rather than worrying about the underlying physical interpretations or philosophical implications!

2.1.2.2 Credits

The redactors have attempted (because the lack of answer is often the rule rather than the exception...) to credit and obtain the necessary authorizations for the use of any material protected by copyright, such as photographs, animations, videos and illustrations from third-party sources.

If, however, copyright infringement is unintentionally committed, we encourage copyright owners to contact us so that we can take appropriate action.

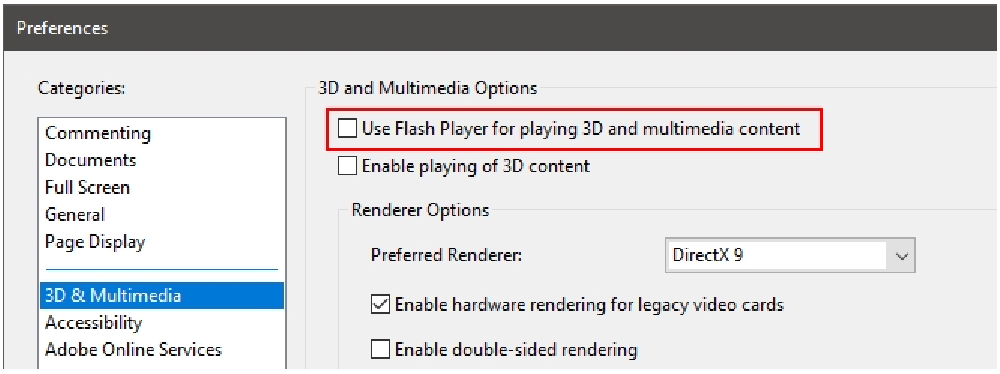
2.1.2.3 Videos and Animations

This textbook contains a dozens of small videos and animations integrated inside the PDF pages themselves. However to be able to play them you will need:

1. Adobe Flash Player for Firefox - NPAPI (the latest version if this technology still exists when you read these lines...)
2. To activate the following option available in most Adobe PDF readers on Microsoft Windows:

---

[2] A companion example to a theorem doesn't have any specific symbol



Preferences

Categories:

- Commenting

3D and Multimedia Options

☐ Use Flash Player for playing 3D and multimedia content

☐ Enable playing of 3D content

Renderer Options

Preferred Renderer: DirectX 9

☑ Enable hardware rendering for legacy video cards

☐ Enable double-sided rendering

This option needs to be reactivate each time you close and reopen the reader depending on your IT policy.

2.1.2.4 Ancillaries

We offer an array of ancillaries for students, instructors and practitioners.

First there are some free companion eBooks and tools in French and English for the people who want to put in practice the theories and models presented in this textbook (see a working and interactive example on a screen may help for the understanding).

Here is the list:

- MATLAB® in English (1,400 pages):
  https://archive.org/details/Matlab
- Maple™ in French (129 pages):
  https://archive.org/details/maple
- R in French (3,134 pages):
  https://archive.org/details/R
- Minitab in French (1,290 pages):
  https://archive.org/details/Minitab
- Scientific Linux installation & Configuration (330 pages):
  https://archive.org/details/scientific-linux-installation

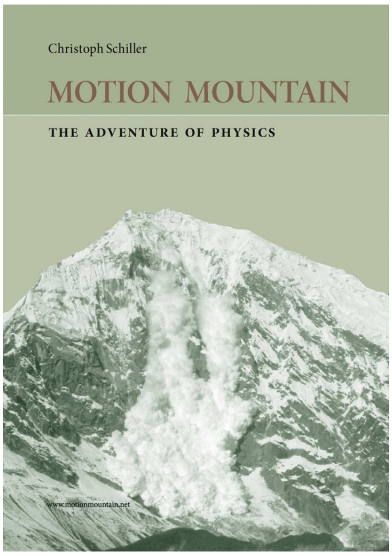
SCIENTIFIC LINUX (SUX)

And as any technical textbook should have a forum, the reader can go through this link for any discussions about the content of this textbook: `https://www.physicsforums.com`.

For people who want to help us to translate this textbook in other languages you can contact us through our social networks.

Because this textbook mainly focus on mathematical aspect of physical phenomena we can only strongly recommend to the reader another free textbook that is in our point of view actually the best one that focus on the popular science aspect of the subjects that we will cover:

Motion Mountain by Dr. Christoph Schiller: `http://www.motionmountain.net`



Christoph Schiller
MOTION MOUNTAIN
THE ADVENTURE OF PHYSICS
www.motionmountain.net

2.1.3 Data Protection

When looking at information on the Internet companion website, some data are automatically saved during a month after which detailed data are destroyed. We try to save as less as possible data and as brief as possible. Wherever we can, we ave only anonymous data. We undertake to process the data you send us personally with the utmost diligence. You can object at any time in the publication of your data by contacting us.

2.1.4 Use of data

Your data are only used for sending the a newsletter. Communication of personal data (except the e-mail address, title and name) is optional. When registering for the newsletter, you can of course specify an alternate address and/or a fictitious name.

2.1.5 Data transmission

We will never sell or commercialize the data of our customers or interested parties and will never affects the rights of the person. In addition, we will not rent mailing lists and will not send you advertising from third parties or on our behalf.

2.1.6 Agreement

When you provide us personal information, you authorize us to save them and use them within the meaning of the Swiss Federal Law on Data Protection. If you ask us not to send you emails, we are obliged, in your interest, save your e-mail in an internal negative list.

2.1.7 Errata

The redactor have made every effort to ensure the accuracy and completeness of the information contained in this textbook. However, we assume no responsibility for any errors, omissions, or differences of opinion that may be present. Readers are strongly advised to consult other scientific peer review sources with high impact factor to supplement and update their knowledge on the topics covered in this textbook.

Illustrations, photographs, and diagrams included in this textbook are for illustrative purposes only and are not intended to be exact representations of the objects or phenomena described. The editors and artists cannot be held responsible for any errors or inaccuracies that these visual elements may contain since they are voluntary for pedagogical reasons!

Although we have taken every care to ensure the accuracy of our content, mistakes do happen. If you find a mistake in this textbook - maybe a mistake in the text, scripts or illustrations - we would be grateful if you would report this to us. By doing so, you can save other readers from frustration and help us improve subsequent versions of this textbook. Our e-mail is given on the footer every page of this textbook. Once your errata are verified, your submissions will be accepted and the error will be visible on the changelog (see page 9347) of updated versions.

2.2. License

The entire contents of this textbook is subject to the GNU Free Documentation License, which means:

- that everyone has the right to freely use the texts for non-commercial usage (Google Ads or any equivalent being considered as a commercial usage!)
- that any person is authorized to broadcast items for non-commercial usage (Google Ads or any equivalent being considered as a commercial usage!)
- that anyone can freely edit the texts for non-commercial usage (Google Ads or any equivalent being considered as a commercial usage!)

and bla bla bla...

in accordance with the license described below:

https://creativecommons.org/licenses/by-nc-sa/4.0/

Version 1.1, March 12000 (holocene calendar)

Copyright (C) 12000 (holocene calendar) Free Software Foundation, Inc. 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

2.2.1 Preamble

The purpose of this License is to make a manual, textbook, or other written document "free" in the sense of freedom: to assure everyone the effective freedom to copy and redistribute it, with or without modifying it only a non-commercial purpose[3]. Secondarily, this License preserves for the author and publisher a way to get credit for their work, while not being considered responsible for modifications made by others.

---

[3] The immediate benefit of this is that you can generate the textbook, with brand new problem sets, and distribute it to your students simply as a PDF (in an email, for instance). But more generally, if you are not keen on the way we explained (or failed to explain) something, then you are free to rewrite it. If you would like to cover more (or less) material, then you are free to add (or delete) whatever Chapters/Sections/Paragraphs that you wish. And since we can provide the source code on request, the reader do not need to reinvent the wheel.

This License is a kind of "copyleft", which means that derivative works of the document must themselves be free in the same sense. It complements the GNU General Public License, which is a copyleft license designed for free software.

We have designed this License in order to use it for manuals for free software, because free software needs free documentation: a free program should come with manuals providing the same freedoms that the software does. But this License is not limited to software manuals; it can be used for any textual work, regardless of subject matter or whether it is published as a printed textbook. We recommend this License principally for works whose purpose is instruction or reference.

2.2.2 Applicability and Definitions

This License applies to any manual or other work that contains a notice placed by the copyright holder saying it can be distributed under the terms of this License. The "Document", below, refers to any such manual or work. Any member of the public is a licensee, and is addressed as "you".

A "Modified Version" of the Document means any work containing the Document or a portion of it, either copied verbatim, or with modifications and/or translated into another language.

A "Secondary Section" is a named appendix or a front-matter section of the Document that deals exclusively with the relationship of the publishers or authors of the Document to the Document's overall subject (or to related matters) and contains nothing that could fall directly within that overall subject (for example, if the Document is in part a textbook of mathematics, a Secondary Section may not explain any mathematics). The relationship could be a matter of historical connection with the subject or with related matters, or of legal, commercial, philosophical, ethical or political position regarding them.

The "Invariant Sections" are certain Secondary Sections whose titles are designated, as being those of Invariant Sections, in the notice that says that the Document is released under this License.

The "Cover Texts" are certain short passages of text that are listed, as Front-Cover Texts or Back-Cover Texts, in the notice that says that the Document is released under this License.

A "Transparent" copy of the Document means a machine-readable copy, represented in a format whose specification is available to the general public, whose contents can be viewed and edited directly and straightforwardly with generic text editors or (for images composed of pixels) generic paint programs or (for drawings) some widely available drawing editor, and that is suitable for input to text formatters or for automatic translation to a variety of formats suitable for input to text formatters. A copy made in an otherwise Transparent file format whose markup has been designed to thwart or discourage subsequent modification by readers is not Transparent. A copy that is not "Transparent" is named "Opaque".

Examples of suitable formats for Transparent copies include plain ASCII without markup, Texinfo input format, LaTeX input format, SGML or XML using a publicly available DTD, and standard-conforming simple HTML designed for human modification. Opaque formats include

PostScript, PDF, proprietary formats that can be read and edited only by proprietary word processors, SGML or XML for which the DTD and/or processing tools are not generally available, and the machine-generated HTML produced by some word processors for output purposes only.

The "Title Page" means, for a printed textbook, the title page itself, plus such following pages as are needed to hold, legibly, the material this License requires to appear in the title page. For works in formats which do not have any title page as such, "Title Page" means the text near the most prominent appearance of the work's title, preceding the beginning of the body of the text.

2.2.3 Verbatim Copying

You may copy and distribute the Document in any medium, non-commercially, provided that this License, the copyright notices, and the license notice saying this License applies to the Document are reproduced in all copies, and that you add no other conditions whatsoever to those of this License. You may not use technical measures to obstruct or control the reading or further copying of the copies you make or distribute. However, you may accept compensation in exchange for copies. If you distribute a large enough number of copies you must also follow the conditions in section 3.

You may also lend copies, under the same conditions stated above, and you may publicly display copies.

2.2.4 Copying in Quantity

If you publish printed copies of the Document numbering more than 100, and the Document's license notice requires Cover Texts, you must enclose the copies in covers that carry, clearly and legibly, all these Cover Texts: Front-Cover Texts on the front cover, and Back-Cover Texts on the back cover. Both covers must also clearly and legibly identify you as the publisher of these copies. The front cover must present the full title with all words of the title equally prominent and visible. You may add other material on the covers in addition. Copying with changes limited to the covers, as long as they preserve the title of the Document and satisfy these conditions, can be treated as verbatim copying in other respects.

If the required texts for either cover are too voluminous to fit legibly, you should put the first ones listed (as many as fit reasonably) on the actual cover, and continue the rest onto adjacent pages.

If you publish or distribute Opaque copies of the Document numbering more than 100, you must either include a machine-readable Transparent copy along with each Opaque copy, or state in or with each Opaque copy a publicly-accessible computer-network location containing a complete Transparent copy of the Document, free of added material, which the general network-using public has access to download anonymously at no charge using public-standard network protocols. If you use the latter option, you must take reasonably prudent steps, when you begin distribution of Opaque copies in quantity, to ensure that this Transparent copy will remain thus accessible at the stated location until at least one year after the last time you distribute an Opaque copy (directly or through your agents or retailers) of that edition to the public.

It is requested, but not required, that you contact the authors of the Document well before redistributing any large number of copies, to give them a chance to provide you with an updated version of the Document.

2.2.5 Modifications

You may copy and distribute a Modified Version of the Document under the conditions of sections 2 and 3 above, provided that you release the Modified Version under precisely this License, with the Modified Version filling the role of the Document, thus licensing distribution and modification of the Modified Version to whoever possesses a copy of it. In addition, you must do these things in the Modified Version:

- Use in the Title Page (and on the covers, if any) a title distinct from that of the Document, and from those of previous versions (which should, if there were any, be listed in the Changelog section of the Document). You may use the same title as a previous version if the original publisher of that version gives permission.
- List on the Title Page, as authors, one or more persons or entities responsible for authorship of the modifications in the Modified Version, together with at least five of the principal authors of the Document (all of its principal authors, if it has less than five).
- State on the Title page the name of the publisher of the Modified Version, as the publisher.
- Preserve all the copyright notices of the Document.
- Add an appropriate copyright notice for your modifications adjacent to the other copyright notices.
- Include, immediately after the copyright notices, a license notice giving the public permission to use the Modified Version under the terms of this License, in the form shown in the Addendum below.
- Preserve in that license notice the full lists of Invariant Sections and required Cover Texts given in the Document's license notice.
- Include an unaltered copy of this License.
- Preserve the section entitled "Changelog", and its title, and add to it an item stating at least the title, year, new authors, and publisher of the Modified Version as given on the Title Page. If there is no section entitled "Changelog" in the Document, create one stating the title, year, authors, and publisher of the Document as given on its Title Page, then add an item describing the Modified Version as stated in the previous sentence.
- Preserve the network location, if any, given in the Document for public access to a Transparent copy of the Document, and likewise the network locations given in the Document for previous versions it was based on. These may be placed in the "Changelog" section. You may omit a network location for a work that was published at least four years before the Document itself, or if the original publisher of the version it refers to gives permission.

- In any section entitled "Acknowledgements" or "Dedications", preserve the section's title, and preserve in the section all the substance and tone of each of the contributor acknowledgements and/or dedications given therein.
- Preserve all the Invariant Sections of the Document, unaltered in their text and in their titles. Section numbers or the equivalent are not considered part of the section titles.
- Delete any section entitled "Endorsements". Such a section may not be included in the Modified Version.
- Do not retitle any existing section as "Endorsements" or to conflict in title with any Invariant Section.
- If the Modified Version includes new front-matter sections or appendices that qualify as Secondary Sections and contain no material copied from the Document, you may at your option designate some or all of these sections as invariant. To do this, add their titles to the list of Invariant Sections in the Modified Version's license notice. These titles must be distinct from any other section titles.
- You may add a section entitled "Endorsements", provided it contains nothing but endorsements of your Modified Version by various parties–for example, statements of peer review or that the text has been approved by an organization as the authoritative definition of a standard.
- You may add a passage of up to five words as a Front-Cover Text, and a passage of up to 25 words as a Back-Cover Text, to the end of the list of Cover Texts in the Modified Version. Only one passage of Front-Cover Text and one of Back-Cover Text may be added by (or through arrangements made by) any one entity. If the Document already includes a cover text for the same cover, previously added by you or by arrangement made by the same entity you are acting on behalf of, you may not add another; but you may replace the old one, on explicit permission from the previous publisher that added the old one.
- The author(s) and publisher(s) of the Document do not by this License give permission to use their names for publicity for or to assert or imply endorsement of any Modified Version.

2.2.6 Combining Documents

You may combine the Document with other documents released under this License, under the terms defined in section 4 above for modified versions, provided that you include in the combination all of the Invariant Sections of all of the original documents, unmodified, and list them all as Invariant Sections of your combined work in its license notice.

The combined work need only contain one copy of this License, and multiple identical Invariant Sections may be replaced with a single copy. If there are multiple Invariant Sections with the same name but different contents, make the title of each such section unique by adding at the end of it, in parentheses, the name of the original author or publisher of that section if known, or else a unique number. Make the same adjustment to the section titles in the list of Invariant Sections in the license notice of the combined work.

In the combination, you must combine any sections entitled "Changelog" in the various original documents, forming one section entitled "Changelog"; likewise combine any sections entitled "Acknowledgements", and any sections entitled "Dedications". You must delete all sections entitled "Endorsements."

2.2.7 Collections of Documents

You may make a collection consisting of the Document and other documents released under this License, and replace the individual copies of this License in the various documents with a single copy that is included in the collection, provided that you follow the rules of this License for verbatim copying of each of the documents in all other respects.

You may extract a single document from such a collection, and distribute it individually under this License, provided you insert a copy of this License into the extracted document, and follow this License in all other respects regarding verbatim copying of that document.

2.2.8 Aggregation with independent Works

A compilation of the Document or its derivatives with other separate and independent documents or works, in or on a volume of a storage or distribution medium, does not as a whole count as a Modified Version of the Document, provided no compilation copyright is claimed for the compilation. Such a compilation is named an "aggregate", and this License does not apply to the other self-contained works thus compiled with the Document, on account of their being thus compiled, if they are not themselves derivative works of the Document.

If the Cover Text requirement of section 3 is applicable to these copies of the Document, then if the Document is less than one quarter of the entire aggregate, the Document's Cover Texts may be placed on covers that surround only the Document within the aggregate. Otherwise they must appear on covers around the whole aggregate.

2.2.9 Generating this document

You will need four things to generate this document for yourself:

1. Install MiKTeX
2. Install TeXMaker
3. An internet connection
4. Configure MikTeX as indicated in the remarks at the beginning of the *LaTeX_SciencesCh_EN.tex* file

2.2.10 Translation

Translation is considered a kind of modification, so you may distribute translations of the Document under the terms of the corresponding section about transformation. Replacing Invariant Sections with translations requires special permission from their copyright holders, but you may include translations of some or all Invariant Sections in addition to the original versions of these Invariant Sections. You may include a translation of this License provided that you also include the original English version of this License. In case of a disagreement between the translation and the original English version of this License, the original English version will prevail.

2.2.11 Permissions and Copyrights

Many figures and tables in this textbook have been reproduced from copyrighted sources. Permission from the publishers and authors for the use of the material is gratefully acknowledged. Some of the sources are directly identified in captions and footnotes, while many others are cited by alphanumeric references or specified as unknown (despite some effort to find them).

2.2.12 Termination

You may not copy, modify, sublicense, or distribute the Document except as expressly provided for under this License. Any other attempt to copy, modify, sublicense or distribute the Document is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

2.2.13 Future revisions of this License

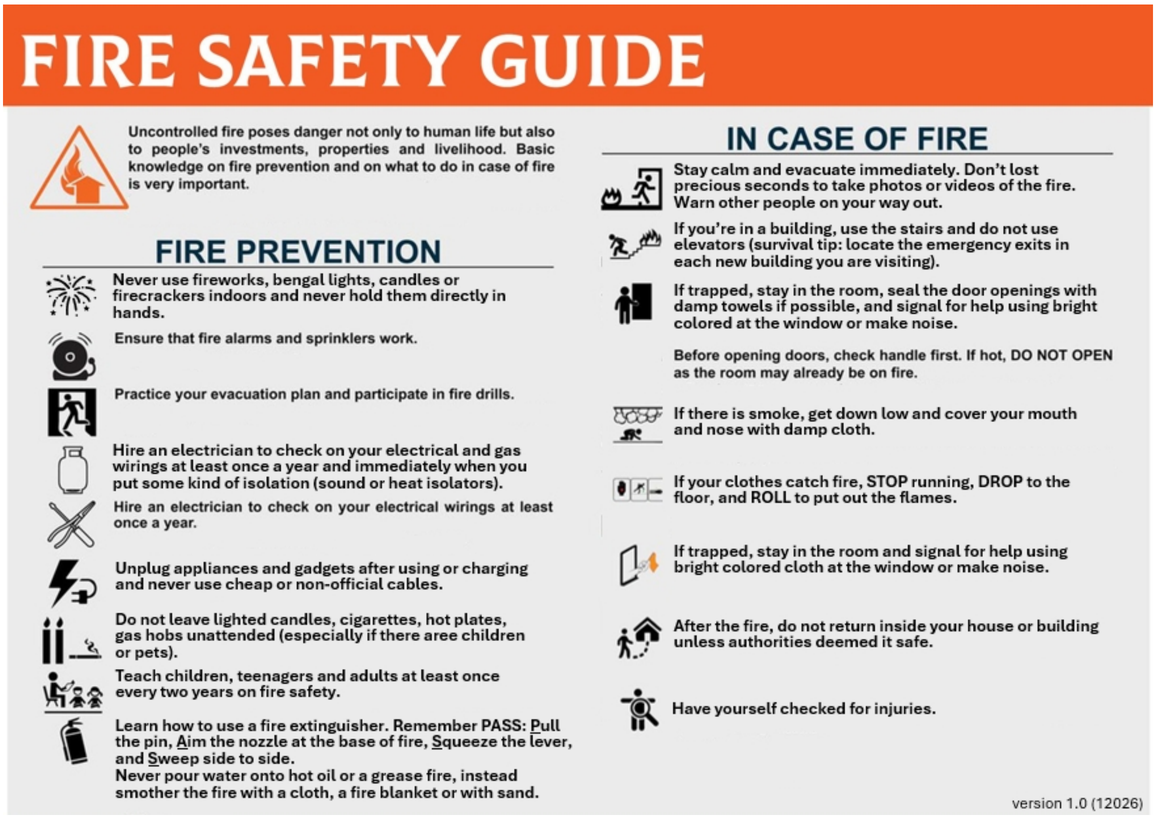
The Free Software Foundation may publish new, revised versions of the GNU Free Documentation License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns. See `http://www.gnu.org/copyleft`.

Each version of the License is given a distinguishing version number. If the Document specifies that a particular numbered version of this License "or any later version" applies to it, you have the option of following the terms and conditions either of that specified version or of any later version that has been published (not as a draft) by the Free Software Foundation. If the Document does not specify a version number of this License, you may choose any version ever published (not as a draft) by the Free Software Foundation.

Please consider the environment before printing

2.3. Safety Guides

Revisiting with fire, chemistry and electrical safety rules every year is essential for physics, chemistry, nuclear and engineering teachers because the subject constantly brings students into contact with heat sources, electrical equipment, components, and experiments that can escalate quickly without disciplined habits; from kindergarten to graduate studies, learners evolve in maturity and technical skill, yet the fundamental risks remain the same, and regular reminders cultivate a culture of vigilance, responsible behavior, and scientific respect for hazardous phenomena. This yearly ritual that should be mandatory starting from kindergarten and displayed in every textbook and on the doors of every lab reinforces not only practical safety but also the deeper message that scientific exploration is inseparable from ethical care for oneself and others, a lesson that grows in importance as students advance toward more complex laboratory work and interacts with complex environments while becoming adults.



FIRE SAFETY GUIDE

Uncontrolled fire poses danger not only to human life but also to people's investments, properties and livelihood. Basic knowledge on fire prevention and on what to do in case of fire is very important.

FIRE PREVENTION

Never use fireworks, bengal lights, candles or firecrackers indoors and never hold them directly in hands.

Ensure that fire alarms and sprinklers work.

Practice your evacuation plan and participate in fire drills.

Hire an electrician to check on your electrical and gas wirings at least once a year and immediately when you put some kind of isolation (sound or heat isolators).

Hire an electrician to check on your electrical wirings at least once a year.

Unplug appliances and gadgets after using or charging and never use cheap or non-official cables.

Do not leave lighted candles, cigarettes, hot plates, gas hobs unattended (especially if there aree children or pets).

Teach children, teenagers and adults at least once every two years on fire safety.

Learn how to use a fire extinguisher. Remember PASS: Pull the pin, Aim the nozzle at the base of fire, Squeeze the lever, and Sweep side to side.
Never pour water onto hot oil or a grease fire, instead smother the fire with a cloth, a fire blanket or with sand.

IN CASE OF FIRE

Stay calm and evacuate immediately. Don't lost precious seconds to take photos or videos of the fire. Warn other people on your way out.

If you're in a building, use the stairs and do not use elevators (survival tip: locate the emergency exits in each new building you are visiting).

If trapped, stay in the room, seal the door openings with damp towels if possible, and signal for help using bright colored at the window or make noise.

Before opening doors, check handle first. If hot, DO NOT OPEN as the room may already be on fire.

If there is smoke, get down low and cover your mouth and nose with damp cloth.

If your clothes catch fire, STOP running, DROP to the floor, and ROLL to put out the flames.

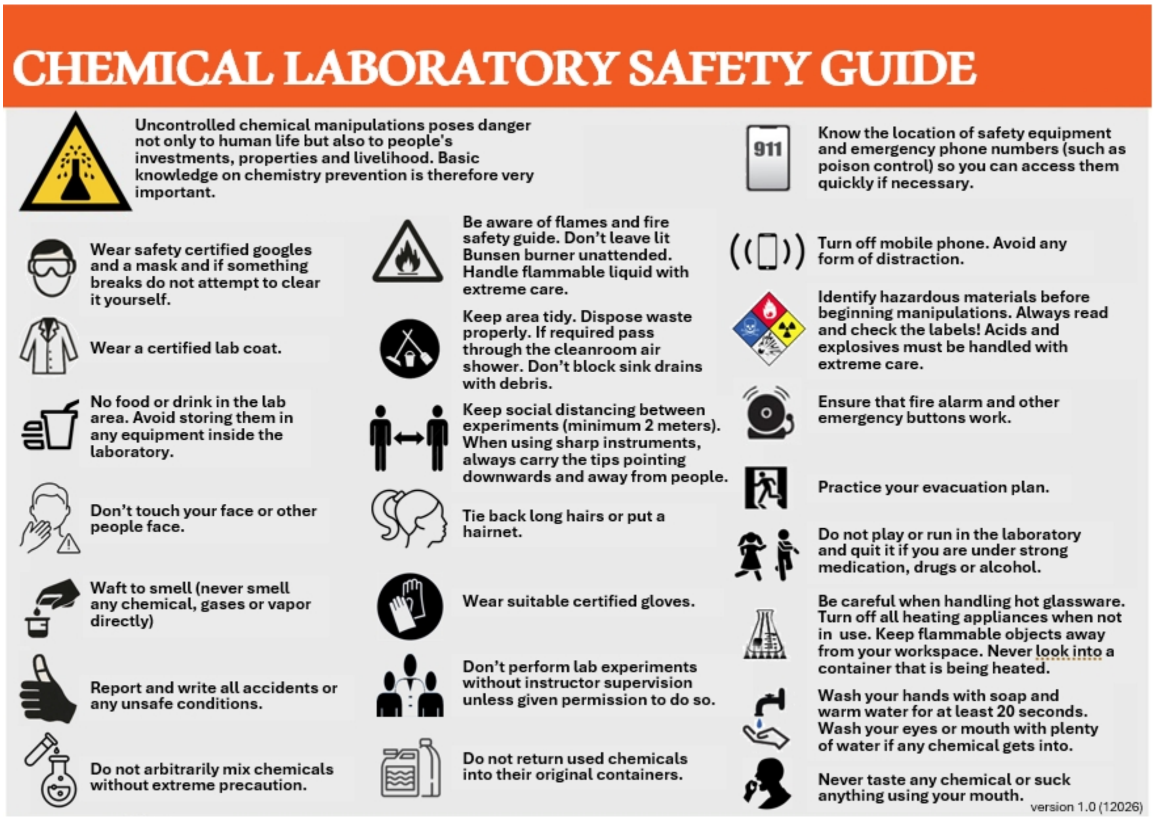
If trapped, stay in the room and signal for help using bright colored cloth at the window or make noise.

After the fire, do not return inside your house or building unless authorities deemed it safe.

Have yourself checked for injuries.

version 1.0 (12026)

Figure 2.2: Fire safety guide



CHEMICAL LABORATORY SAFETY GUIDE

Uncontrolled chemical manipulations poses danger not only to human life but also to people's investments, properties and livelihood. Basic knowledge on chemistry prevention is therefore very important.

Wear safety certified googles and a mask and if something breaks do not attempt to clear it yourself.

Wear a certified lab coat.

No food or drink in the lab area. Avoid storing them in any equipment inside the laboratory.

Don't touch your face or other people face.

Waft to smell (never smell any chemical, gases or vapor directly)

Report and write all accidents or any unsafe conditions.

Do not arbitrarily mix chemicals without extreme precaution.

Be aware of flames and fire safety guide. Don't leave lit Bunsen burner unattended. Handle flammable liquid with extreme care.

Keep area tidy. Dispose waste properly. If required pass through the cleanroom air shower. Don't block sink drains with debris.

Keep social distancing between experiments (minimum 2 meters). When using sharp instruments, always carry the tips pointing downwards and away from people.

Tie back long hairs or put a hairnet.

Wear suitable certified gloves.

Don't perform lab experiments without instructor supervision unless given permission to do so.

Do not return used chemicals into their original containers.

Know the location of safety equipment and emergency phone numbers (such as poison control) so you can access them quickly if necessary.

Turn off mobile phone. Avoid any form of distraction.

Identify hazardous materials before beginning manipulations. Always read and check the labels! Acids and explosives must be handled with extreme care.

Ensure that fire alarm and other emergency buttons work.

Practice your evacuation plan.

Do not play or run in the laboratory and quit it if you are under strong medication, drugs or alcohol.

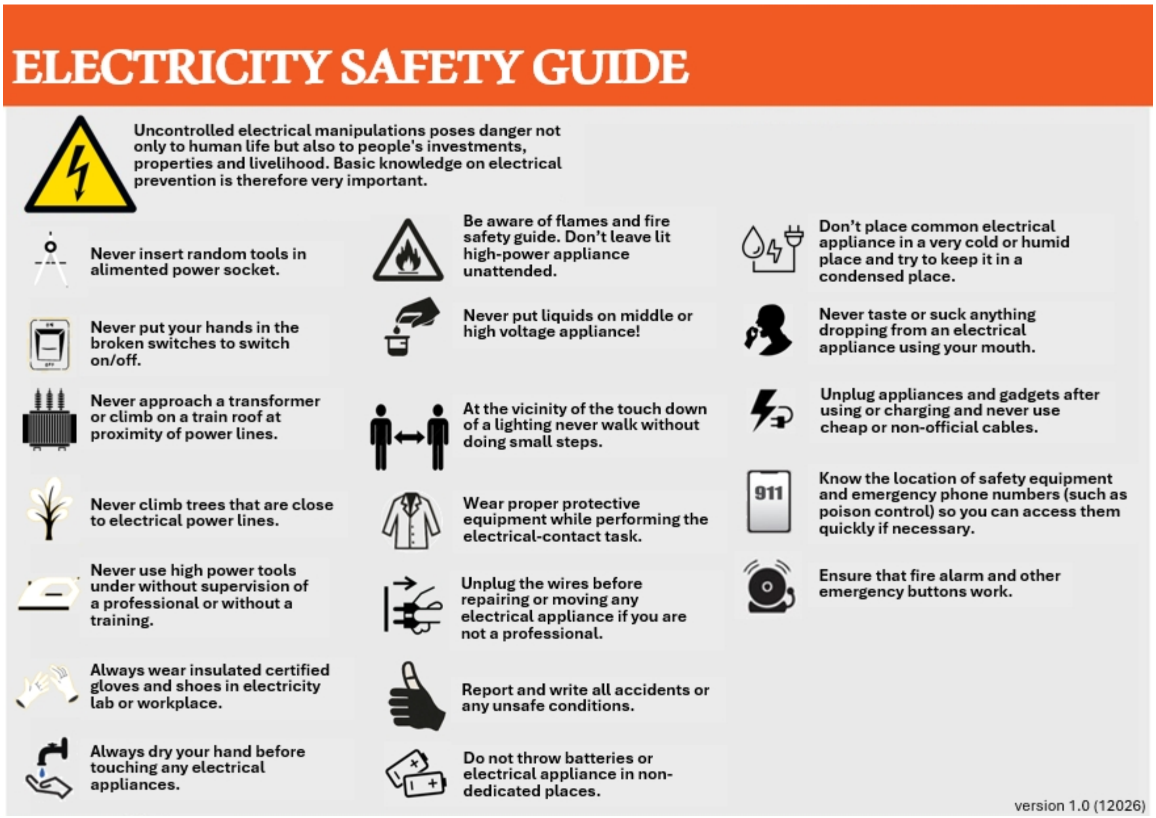
Be careful when handling hot glassware. Turn off all heating appliances when not in use. Keep flammable objects away from your workspace. Never look into a container that is being heated.

Wash your hands with soap and warm water for at least 20 seconds. Wash your eyes or mouth with plenty of water if any chemical gets into.

Never taste any chemical or suck anything using your mouth.

version 1.0 (12026)

Figure 2.3: **Chemical laboratory safety guide**



ELECTRICITY SAFETY GUIDE

Uncontrolled electrical manipulations poses danger not only to human life but also to people's investments, properties and livelihood. Basic knowledge on electrical prevention is therefore very important.

Never insert random tools in alimented power socket.

Never put your hands in the broken switches to switch on/off.

Never approach a transformer or climb on a train roof at proximity of power lines.

Never climb trees that are close to electrical power lines.

Never use high power tools under without supervision of a professional or without a training.

Always wear insulated certified gloves and shoes in electricity lab or workplace.

Always dry your hand before touching any electrical appliances.

Be aware of flames and fire safety guide. Don't leave lit high-power appliance unattended.

Never put liquids on middle or high voltage appliance!

At the vicinity of the touch down of a lighting never walk without doing small steps.

Wear proper protective equipment while performing the electrical-contact task.

Unplug the wires before repairing or moving any electrical appliance if you are not a professional.

Report and write all accidents or any unsafe conditions.

Do not throw batteries or electrical appliance in non-dedicated places.

Don't place common electrical appliance in a very cold or humid place and try to keep it in a condensed place.

Never taste or suck anything dropping from an electrical appliance using your mouth.

Unplug appliances and gadgets after using or charging and never use cheap or non-official cables.

Know the location of safety equipment and emergency phone numbers (such as poison control) so you can access them quickly if necessary.

Ensure that fire alarm and other emergency buttons work.

2.4. Roadmap (To Do)

This textbook has a simple progression rule that is: 1 new A4 page per day since May 12001 (holocene calendar) on subjects that interest the supervisor of the *Original* distribution of the textbook *Opera Magistris*. The following subjects below are already planned - of course any external help is welcome! - for a near or far future still with the same level of details and pedagogical approach in the proofs as the rest of the textbook (all the subjects below should take almost $1,500$ to $2,500$ pages and are already in writing progress):

- Introduction:
    - Add acknowledgements to all people that who have developed MikTeX/LaTeX distro and packages used for this textbook
- Proof Theory:
    - Modal logic
    - Probabilistic logic
    - Statistical abduction
- Probabilities:
    - Explaining conditional plots and spinplots
    - Hidden Markov Chains
    - Fuzzy probability
- Statistics:
    - Mode and Median of statistical laws
    - Bayesian rating average
    - Derivation of standard error of the β of Cox proportional hazard model
    - Likelihood of censored data
    - Normal Law Entropy
    - Propension score
    - Standardized Pearson residuals
    - ANCOVA
    - Wald-Wolfowitz test (binary sequence)
    - Levene-Wolfwitz test[4] (continuous up/down sequence)
    - Ellipse of control

---

[4] also named "turning point test" or "trend test"

  - Ansari-Bradley test
  - Homogeneity of variances tests (Levene, Bartlett, Fligner, Brown-Forsythe)
  - Regular Dickey-Fuller test
  - Augmented Dickey-Fuller test
  - Canonical Correlation
  - G-test of periodicity
  - Gaussian and Student copula
  - Extreme Values Theory
  - Pickands-Balkema-De Haan theorem
  - Schoenfeld's global test for Cox proportional hazards model
  - Survey Theory
  - Canonical Analysis
  - Tucker's Inter-battery factor analysis
  - PLS regression (partial least squares)
  - Two-Stage Least Squares (2SLS) regression
  - Logic regression
  - Adjusted Chi-squared
  - Schoenfeld residuals
  - Jarque-Bera test
  - Dixon, Grubbs, Chi-square outliers tests
  - Somers'd rank coefficient
  - Kaplan-Meier sample size[5]
  - Weighted PCA
  - Bayesian ANOVA
  - Bayesian one sample T-test
  - Bayesian binomial test
  - Bayesian multinomial test
  - Bayesian Mann-Withney test
  - Bayesian correlation
  - Bayesian contingency tables

- Geometry:
  - Gauss remarkable theorem (Theorema Egregium)

- Differential Calculus
  - Lebesgue Integral with numerical application in MATLAB®

---

[5] Sample size calculation: Survival analysis (logrank test)

  - Heun function

- Analysis:
  - Finish the discrete Fourier transformation
  - Finish to introduce the unilateral Laplace transformation
  - Finish to introduce the Hilbert transformation
  - Fourier inequality
  - Add a section with the detailed proof that the euclidean, manhattan, chebychev, minkowski, cosine, pearson, mahalanobis, haversine, jaccard, family-tree, jensen-shannon, chi-square, canberra, spearman, hamming and levenstein distances respect the four axioms of a metric
- Complex Analysis:
  - Residue Theorem for polynomial ratios
- Differential Geometry:
  - Finish to introduce the isometric perspective
  - Normal coordinates
  - Gauss curvature
  - Circumference on a plane, sphere and hyperbolic surface
- Principia:
  - Charge conservation according to Noether theorem (global gauge symmetry)
- Mechanics:
  - Flow through submerged orifice
  - Intermediate axis theorem
  - Flow over notches and weirs
  - Force due to the flow around a pipe bend
  - Force on a pipe nozzle
  - Impact of a jet on plane
  - Force due to a jet hitting an inclined plane
  - Fluid Hammer Effect
  - Kelvin-Helmholtz instability
  - Saint-Venant equations
  - Kutta-Joukowski lift
  - Layer Boundary (Blasius boundary layer)
- Statistical Mechanics:
  - Maxwell–Jüttner distribution

- Electrodynamics:
    - Electromagnetic Fields of a rotating shell of charge
    - Electromagnet rotor torque
    - Corneal Topography (Pentacam system)
    - Sun glitter
- Electrokinetics:
    - Photoelectric converter
    - Norton and Thevenin theorem
- Astronomy:
    - Venus transit method for the distance of the Sun
    - MacCullagh's formula
    - Body flatness indirect calculation
    - Synchronous locking of tidally evolving satellites
    - Flatness spheroid
    - Oberth Effect
    - Clairaut's theorem
    - Planetary departure
    - Nutation-precession calculation method of planets
- Astrophysics:
    - Worm holes
    - Tolman-Oppenheimer-Volkoff limit
    - Hawking's Radiation
    - Black Hole life-time (based on Hawking's radiation)
- General Relativity:
    - Real volume of an object in General Relativity
    - Einstein radius derivation
    - General Birkhoff's theorem
    - Global Positioning System (GPS)
    - Kerr metric and Kerr solution (+ergosphere)
    - Naked singularities
    - Lense–Thirring precession
- Cosmology:
    - Kaluza-Klein theory

  - Inflation theory
  - Borde-Guth-Vilenkin theorem (BGV)
  - Derivation of Wheeler-DeWitt metric
  - Cosmic inflation theory (i.e. Big Bang) Nucleosynthesis
  - Inflationary space-time is past-incomplete
- Nuclear Physics:
  - Critical mass
  - Neutron transport
  - Bateman equation
  - Compton scattering cross section classical derivation
- Wave Quantum Physics:
  - Bell inequalities
  - Lamb shift detailed calculation
  - Davisson-Germer experiment
  - EPR paradox formalism
  - Hydrogen fine structure derivation
  - Multiphoton ionization
  - Entanglement
- Relativistic Quantum Physics:
  - Photon "spin" (helicity) and polarity relation
  - Parity, charge conjugation and time reversal for electroweak theory
  - Free Dirac equation covariance proof
- Quantum Field Theory:
  - Second quantization
  - Brout-Englert-Higgs mechanism
  - Feynman rules and Feynman diagrams
  - Dyson series
  - Light-Light scattering
  - Wigner-Weisskopf theory of spontaneous decay
- Quantum Chemistry:
  - Valence shell electron pair repulsion theory
  - Density Functional Theory (DFT)
  - Hund's rules

- Numerical Methods:
  - Relational algebra
  - Monte Carlo Markov chains
  - Univariate optimization problem with substitution method
  - Acceptation/Rejection Sampling
  - Gibbs Sampling
  - Cronbach coherence indicator
  - Quadratic discriminant Analysis (QDA)
  - Multiple Correspondence Analysis
  - Linear Mixture Model (LMM)
  - Generalized Least Squares (GLS)
  - Correspondence Factor Analysis
  - Generalized Reduced Gradient (GRG) optimization method
  - Normalized mutual information
  - Chi-squared Automatic Interaction Detector (CHAID)
  - Latent semantic analysis (LSA)
  - Correlation based feature selection
  - PRISM, AQ, CN2 and C4.5 algorithms
  - Procrustes analysis
  - Independent component analysis (ICA)
  - Uplift modelling
  - Differences between natural, basis and restricted cubic splines
  - Gauss-Jordan method
  - Gauss-Seidel method
  - Learning Vector Quantization (LVQ)
  - Karush-Kuhn-Tucker conditions
  - Latin Hypercube Sampling (LHS)
  - Universal Approximation Theorem
- Quantum Computing:
  - No-cloning theorem
- Cryptography:
  - Elliptic curves
- Engineering:
  - Box Domains
  - Definitive Screening Design

  - Split-plots designs
  - Central Composite Design
  - Center Face Cube Design
  - Modelization by structural equations
  - Accelerated life testing
  - Microelectronics (npn/pnp junctions, amplifiers)
  - Stress of a rotating disc and rotating ring
  - Shelf life for Stability Study
  - Trochoidal waves (i.e. Gerstner waves)
  - Atmospheric tides
  - Soliton wave (Korteweg de Vries equation)

- Game Theory:
  - Coalition
  - Shapley value
  - Arrow's impossibility theorem

- Economy:
  - Continuous yield rate (Nielson-Siegel)
  - Equivalence of an obligation rate for a treasure bond
  - Options Portfolio hedging
    - Protective Put/Call
    - Bull Spread/Call
    - Bear Spread/Call
    - Butterfly
    - Straddle
    - Strangle
    - Collar
    - Box spreads
    - Calendar spreads
  - Jarrow-Rudd, Tian and Leisen-Reimer binomial models
  - Greeks for binomial trees
  - Swaps
  - Black-Litterman portfolio
  - Margrabe's formula
  - Kirk's (approximation) formula
  - CreditRisk+
  - Fokker-Planck equation

  - Vector autoregressive models for multivariate time series
  - Granger test for times series causation
  - Event Study Analysis
  - Kalman Filter
  - Heston option pricing model
  - Spread option pricing
  - Cornish-Fisher VaR
  - Close to close, Parkinson, Garman-Klass, Rogers-Satcheli, Garman-Klass Yang-Zhang, Yang-Zhang volatility estimates
  - Asian geometric and arithmetic average option pricing
  - Digital options
  - Dynamic stochastic general equilibrium
  - Wold's theorem
  - Changepoint detection analysis
  - SABR model closed form approximate solution
  - RAROC, RORAC, RARORAC
  - Causal Inference (instrumental variables, panel data, difference in difference, regression discontinuity, potential outcome modeling)

- Quantitative Management:
  - Gale-Shapley Algorithm
  - Pareto/NBD, BG/NBD and BG/BB customer lifetime value models
  - Bullwhip Effect
  - Condorcet paradox
  - Computerized Relative Allocation of Facilities Technique (CRAFT)
  - Differed Capital in living case (life assurance)
  - CBOE's Volatility Index (started but not finished)
  - Death differed temporary (life assurance)
  - Ponzi system and pyramid scheme

- Population Dynamics:
  - Neutral theory of molecular evolution

- Biographies:
  - On the request of a reader, add for each biography the religion

Furthermore we want to compile a summarized version of this PDF (without the detailed developments but only with the main results) and a companion presentation including slides (typically made with Beamer) only with the main results, texts and pictures/plots that could be usable by any teacher for free around the World.

Remember that the LaTeX sources of this textbook (with the equations and TikZ/Pgfplots codes!) can be obtained actually depending on your donation on Patreon, Paypal, Tipeee or if you participate to the translation of the textbook in another language.

A copy of the PDF file is available at the Internet Archive (540 Megabytes PDF...):

Acknowledgements

The ideas and evidence compiled in this textbook have been developed and reinforced by many people during the twenty years of its redaction. I have greatly benefited from my regular interactions with students (university, engineering schools) and executives from all backgrounds, including CEOs, CFOs, PMs of many companies around the world, teaching sessions, developing company-specific programs, consulting, and even informal conversations. I am grateful to them for sharing their wisdom and experience with me and inspiring many of the ideas in the book. I am also grateful to all scientists, economists, engineers, illustrators and science popularizers of the last millennial without who this textbook would not exist in it's actual shape. This includes the following approximately $1,500$ people:

John Cannin, Karl Brandan Mollweide, Howard Haber, Juan F. G. Cascales, Forhad Ahmed, Xavier Hubaut, Sanjay Sekaran, William George Horner, Adrian Olszweski, Anders Jensen, Wojciech Kotłowski, Saed Sayad, Federico Errica, Shi Yan, Karl Pearson, Louis Agassiz, Maria Gaetana Agnesi, Al-Battani, Christrophe Michel, Abu Nasr Al-Farabi, Alhazen, Jim Al-Khalili, Muhammad Ibn Musa al-Khwarizmi, Mihailo Petrovic Alas, Angel Alcala, Vesto Slipher, Salim Ali, Luis Alvarez, Andre Marie Ampère, Anaximander, Carl David Anderson, Mary Anning, Milner Baily Schaefer, Charles Geschke, Virginia Apgar, Archimedes of Syracuse, Agnes Arber, Aristarchus of Samos, Aristotle, Svante Arrhenius, Oswald Avery, Amedeo Avogadro, Waloddi Weibull, David Brewster, Avicenna, Charles Babbage, Francis Thomas Bacon, Alexander Bain, T. Johnson, John Logie Baird, Pierre Barbier, Joseph Banks, Ramon Barba, John Bardeen, Fjodor van Veen, Donald E. Knuth, Paul Gingrich, Leonard Henry Caleb Tippett, Benoît de Maillet, Charles Barkla, Stichting Tegenbeld, Pablo Carlos Budassi, Ibn Battuta, William Bayliss, Colin Maclaurin, Neyman Jerzy, George Beadle, Arnold Orville Beckman, Henri Becquerel, Georges Geiser, Gilles Delpin, Steven Weinberg, R. Obviously... the views expressed in this textbook are those of the redactors and do not necessarily reflect the views of all the people cited above!

This textbook would not have been possible without the valuable support of the people mentioned below who greatly helped to make original texts more readable for the layman. They find here the expression of my gratitude (and for sure if some errors remains in this textbook this is obviously their fault...):

- **HARMEL Léon** (†12012), graduate electrical engineer with a specialization in electronics and automation, responsible in the physical research laboratory at ACEC in Charleroi (BEL), for the redaction of almost 400 pages used in the sections of Corpuscular Quantum Physics, Wave Quantum Physics, Quantum Field Theory, Spinor Calculus and General Relativity.

- **KOLANI Daname**, PhD student in portfolio management at UM5-Rabat (MAR) for his help on the redaction of almost 700 pages of the `R` and MATLAB® companion books, proofreading and complements of the section in this textbook about data mining and machine learning and translation of a few hundred pages of the original french website into this LaTeX book.

- **LEGRAND Mathias**, PhD of the École Centrale de Nantes (FRA) for his help on the translation of the first 550 pages of the original french website into this LaTeX book.

- **RICCHIUTO Ruben**, engineer degree in physics HES (B.Sc.) from the Engineering School of Geneva (CHE) and mathematician from the University of Geneva for his valuable help (almost 150 pages) in plasma physics, electromagnetism, quantum physics, statistics, topology, quantum chemistry, fractals theory, analysis and many other areas affecting pure mathematics and computing.

- The regular users of Les Mathematiques.net, Futura-Sciences.com, Maths Stackexchange.com, Physics Stackexchange.com and LaTeX Stackexchange.com forums, for their valuable assistance in many areas of mathematics and physics. The debates and discussions that took place on the forums helps to constantly improve the educational aspect of this textbook.

- The Wikipedia, Wikipedia and ProofWiki websites to whom I am indebted to many borrow almost word by word (and this seems sometimes to be mutual...).

- The support of some artificial intelligences like Microsoft Copilot, Goole Bard, NotebookLM to improve some sentences, proofs and create a few illustrations.

- The professors Gabriel Nagy of Michigan State University, Liam Revell of Massachusetts Boston University, Jorge Cham (of PhD Comics), Lili Xiao (Department of Mathematical Sciences, Tsinghua University, Beijing, China), Dennis K. J. Lin (Department of Statistics, Pennsylvania State University), Fengshan Bai (Department of Mathematical Sciences, Tsinghua University, Beijing, China) and the OpenStax team that have received and read my multiple e-mails inquiries about images credits and texts credits but who never answered to me (not quite good examples of what should be the "scientific collaboration and spirit"...)

And thanks to all readers, webmasters and teachers for their websites and quality documents available for free and anonymously on the Internet and also to regular forum stakeholders. I sometimes verbatim recovered their explanations that didn't require additions or corrections. It's probably needless to say that the reader should not assume that these people are in total agreement with the scientific purposes views expressed in this textbook; and are not responsible for any errors or obscurities that the reader might accidentally find in it.

Thanks also to the few colleagues and customers who were willing to give me their comments to improve the content of this textbook. However, it is certain that it can still be improved on many points.

Several scientific figures were kind enough to support us in our approach to providing free, high-quality access to a scientific reference compendium for the general public. Here are their encouragements:

Les concepts et les mots pertinents de la science
sont, tôt ou tard, destinés à être exprimés
en concepts et en mots qui ont un sens pour
le public instruit, et à s'inscrire dans une
image générale du monde. Le site www.sciences.ch
œuvre admirablement pour cette noble entreprise.
En faisant jaillir l'émotion du savoir réputé froid,
le site ouvre les portes à la surprise, à la
curiosité, à l'humour, à l'émerveillement

PhD. Jean-Pierre Luminet (11951-) French astrophysicist specializing in black holes and cosmologyand emeritus research director at the CNRS

Comment se passer de la science
si l'on cherche la lucidité ?

PhD. Albert Jacquard (11925 – 12013) French genetics popularizer of science and essayist

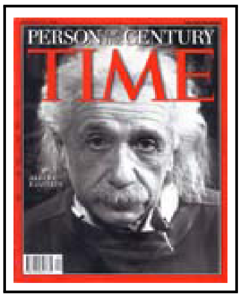
4.6 Is Science dogmatic? 120



This textbook whose first edition has been published in 12001 is designed so that the knowledge required to read it is as basic as possible. It is not necessary to have a PhD to consult it, you just have to know reasoning, to think critically, to observe and have a lot of free time available...

"Simplicity is the seal of truth and it radiates beauty"
Albert Einstein

4.1. Forewords

It is very likely that no human endeavour has had more impact than Science[1] on our lives, our conception of the Universe and ourselves these last centuries. Its theories, models and methodologies conquests and results are all around us in our industrial countries for the best and also sometimes... for the worst.

Omnipresent in the industry (aerospace, imaging, cryptography, transportation, chemistry, algorithmic, etc.) or in the services (banking, fintech, insurance, human resources, projects, logistics, architecture, communications, etc.), Applied Mathematics are a powerful tool that approximated very well our reality and that also appear in many other areas like: surveys, risk modelling, data protection, politics, etc. Applied Mathematics (also sometimes named "Mathematics Machinery") influence our lives (telecommunications, transport, medicine, meteorology, music, project management) and contribute to the resolution of current issues: energy, health, environment, climate, optimization, sustainable development, etc. much more than any soft skill technique or methodology! They great success are their fabulous dispersion in the real world and their increasing integration in all human and artificial intelligence activities. We are going therefore to a situation where mathematicians and engineers will no longer have the monopoly of mathematics, but where almost any graduate job position will have to do advanced mathematics in a way or an other.

As a former student in the field of engineering I have often regretted the absence of a single textbook fairly comprehensive, detailed (without going to the extreme...) and educational if possible free (!) and portable (being personally a fan of eBooks...) containing at least a non exhaustive idea of the overall program of Applied Mathematics in engineering schools with an overview of what is used for real in companies with more intuitive than rigorous proofs but with enough details to avoid unnecessary effort to the reader. Also a textbook that does not require the reader to adopt each time a new notation or terminology specific to the author when it is not outright to change to a foreign language... and where anyone can suggest improvements or additions (through the forum, guest-books or by e-mail).

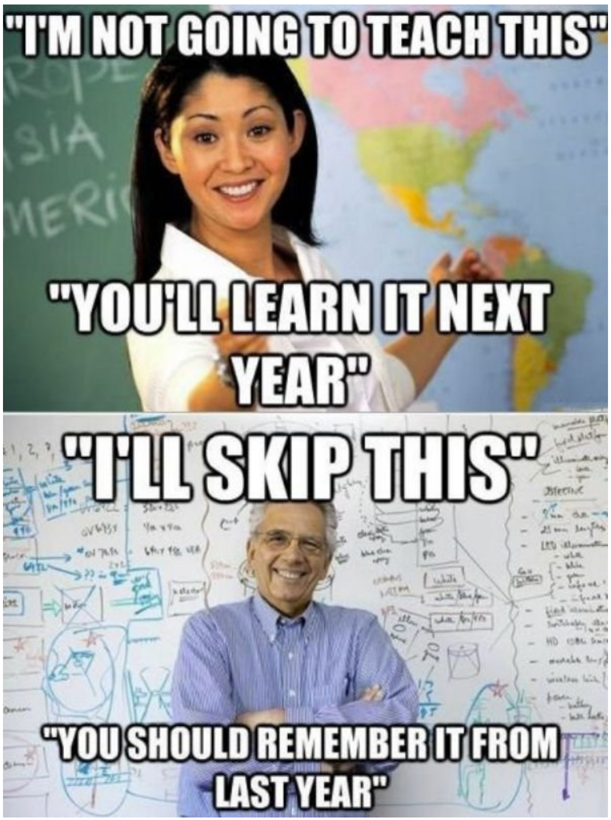
I was also frustrated during my studies to have quite often have to swallow "formulas" or "laws[2]" supposedly (and wrongly) non-provable or too complicated as my teachers says or even disappointed by renowned authors textbooks (where developments are left to the reader or as exercise and no real applications are even mention...).

---

[1] From Latin *scientia* "knowledge, a knowing, expertness". Itself from *sciens* (genitive scientis) that means "intelligent, skilled", present participle of *scire* that means "to know" probably originally comes from "to separate one thing from another, to distinguish" related to *scindere* "to cut, divide".

[2] "Laws" are descriptive in Science not prescriptive like in religions or in human legal system.

In this textbook predominates the will to avoid to confuse the reader with a majority of empty sentences like "it is evident that...", "it is easy to prove that...", "we leave it to the reader as an exercise...", "it should be known that...", since all developments are presented - we expect - in sufficient detail. But I'm not a purist of maths! I have only one ambition: to explain things the easiest possible possible without loosing too much rigour.



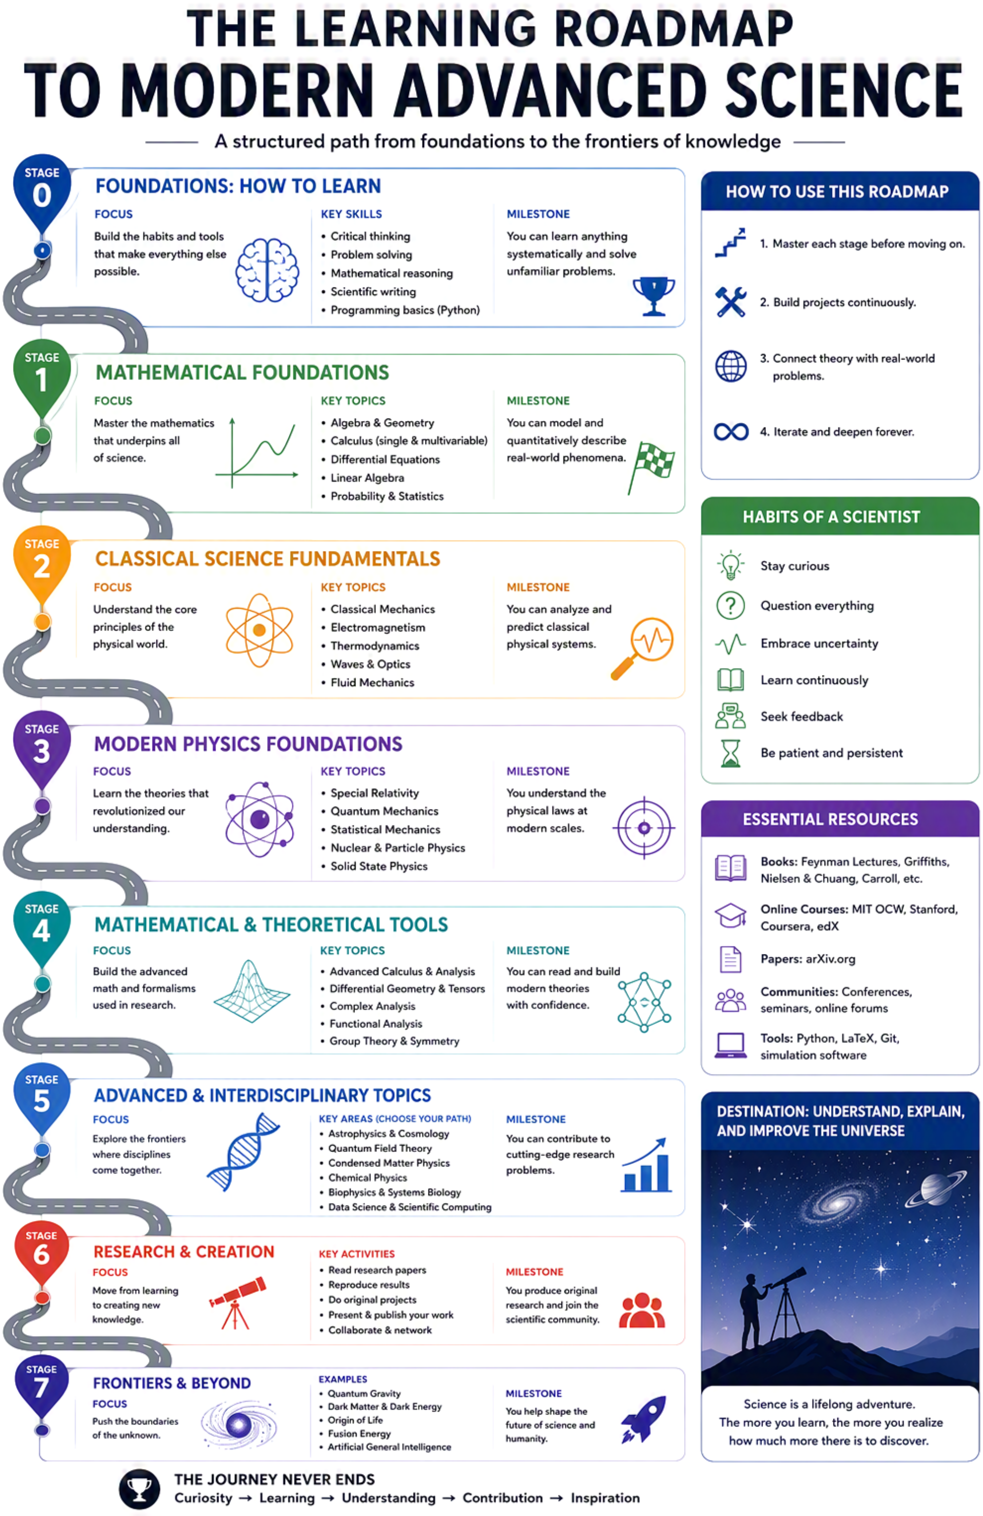
"I'M NOT GOING TO TEACH THIS"
"YOU'LL LEARN IT NEXT YEAR"
"I'LL SKIP THIS"
"YOU SHOULD REMEMBER IT FROM LAST YEAR"

Figure 4.1: **Typical kind of situation we want to avoid in this textbook**

Although I have to admit that prove some mathematical relations presented within the engineering schools curriculum can not be done because of a lack of time in the official program or size limit in a textbook, I can not accept that a teacher or author tells his students (respectively, his readers) that some relations are non-provable (because most of the time this is not true!) or that such or such proof is too complicated without giving a reference (where the student can find the information necessary to satisfy his curiosity) or at least a simplified but satisfactory proof.

Moreover, I think that it is totally archaic today that some teachers continue to ask to their students to take a massive quantity of notes during classes. It would be much more favourable and optimal to distribute a course handout containing all the details in order to be able to concentrate on the essentials points with students, that is to say the oral explanations, interpretations, understanding, reasoning, critical thinking and practice rather than excessive and time-consuming blackboard copy... Obviously by giving a complete course handout some students will be brilliant by their absence but ... it is the better! Thus, those who are passionate can deepen subjects at home or at the university library, the weak do what they have to do and the rest (struggling students but workers) will follow the course given by the teacher to profit to ask questions rather than mindlessly copying a blackboard.

Inspired on a learning model of an American scholar, whose I forgot the name (...), this textbook proposes and imposes the following properties to the reader: discover, memorize, cite, integrate, explain, restate, infer, select, use, decompose, compare, interpret, judge, argue, model, develop, create, search, reasoning, develop in a clear progressive teaching way to develop the analytic skills and openness.



THE LEARNING ROADMAP
TO MODERN ADVANCED SCIENCE

A structured path from foundations to the frontiers of knowledge

STAGE 0 — FOUNDATIONS: HOW TO LEARN

FOCUS
Build the habits and tools that make everything else possible.

KEY SKILLS
- Critical thinking
- Problem solving
- Mathematical reasoning
- Scientific writing
- Programming basics (Python)

MILESTONE
You can learn anything systematically and solve unfamiliar problems.

STAGE 1 — MATHEMATICAL FOUNDATIONS

FOCUS
Master the mathematics that underpins all of science.

KEY TOPICS
- Algebra & Geometry
- Calculus (single & multivariable)
- Differential Equations
- Linear Algebra
- Probability & Statistics

MILESTONE
You can model and quantitatively describe real-world phenomena.

STAGE 2 — CLASSICAL SCIENCE FUNDAMENTALS

FOCUS
Understand the core principles of the physical world.

KEY TOPICS
- Classical Mechanics
- Electromagnetism
- Thermodynamics
- Waves & Optics
- Fluid Mechanics

MILESTONE
You can analyze and predict classical physical systems.

STAGE 3 — MODERN PHYSICS FOUNDATIONS

FOCUS
Learn the theories that revolutionized our understanding.

KEY TOPICS
- Special Relativity
- Quantum Mechanics
- Statistical Mechanics
- Nuclear & Particle Physics
- Solid State Physics

MILESTONE
You understand the physical laws at modern scales.

STAGE 4 — MATHEMATICAL & THEORETICAL TOOLS

FOCUS
Build the advanced math and formalisms used in research.

KEY TOPICS
- Advanced Calculus & Analysis
- Differential Geometry & Tensors
- Complex Analysis
- Functional Analysis
- Group Theory & Symmetry

MILESTONE
You can read and build modern theories with confidence.

STAGE 5 — ADVANCED & INTERDISCIPLINARY TOPICS

FOCUS
Explore the frontiers where disciplines come together.

KEY AREAS (CHOOSE YOUR PATH)
- Astrophysics & Cosmology
- Quantum Field Theory
- Condensed Matter Physics
- Chemical Physics
- Biophysics & Systems Biology
- Data Science & Scientific Computing

MILESTONE
You can contribute to cutting-edge research problems.

STAGE 6 — RESEARCH & CREATION

FOCUS
Move from learning to creating new knowledge.

KEY ACTIVITIES
- Read research papers
- Reproduce results
- Do original projects
- Present & publish your work
- Collaborate & network

MILESTONE
You produce original research and join the scientific community.

STAGE 7 — FRONTIERS & BEYOND

FOCUS
Push the boundaries of the unknown.

EXAMPLES
- Quantum Gravity
- Dark Matter & Dark Energy
- Origin of Life
- Fusion Energy
- Artificial General Intelligence

MILESTONE
You help shape the future of science and humanity.

HOW TO USE THIS ROADMAP

1. Master each stage before moving on.
2. Build projects continuously.
3. Connect theory with real-world problems.
4. Iterate and deepen forever.

HABITS OF A SCIENTIST

- Stay curious
- Question everything
- Embrace uncertainty
- Learn continuously
- Seek feedback
- Be patient and persistent

ESSENTIAL RESOURCES

- **Books:** Feynman Lectures, Griffiths, Nielsen & Chuang, Carroll, etc.
- **Online Courses:** MIT OCW, Stanford, Coursera, edX
- **Papers:** arXiv.org
- **Communities:** Conferences, seminars, online forums
- **Tools:** Python, LaTeX, Git, simulation software

DESTINATION: UNDERSTAND, EXPLAIN, AND IMPROVE THE UNIVERSE

Science is a lifelong adventure.
The more you learn, the more you realize how much more there is to discover.

THE JOURNEY NEVER ENDS
Curiosity → Learning → Understanding → Contribution → Inspiration

So, in my mind, this non-exhaustive textbook (and its associated companion PDFs) must be a substitute, free of charge for all students and employees around the World, to many references and gaps of the scholar system, allowing any curious student not to be frustrated for many years during his academic curriculum. Otherwise, the science of the engineer could have the aspect of a frozen science, apart from the scientific and technical developments, a heterogeneous accumulation of knowledge and especially of formulas which made he considered as a tasteless subproduct of mathematics and that brings companies and governments to many false results and bad decisions...

This textbook has also been designed to meet the needs of executives, both finance as well as non-finance managers. Any executive who wants to probe further and grasp the fundamentals of strategic finance, strategic marketing or project management engineering and supply chain issues will benefit from its lecture.

This textbook has also for purpose to describe and explain how our observable Universe and our World (also other "worlds" in our Universe) works in a much more accurate, more complete and detailed way than any Holy book. This textbook will give you help the reader to understand how science is done and how scientists and engineers work, it will provide the reader models and quantification methods for the origin of species, of galaxies, of planets, of quantum phenomenon, of physics movements, of stellar physics, of extreme observable events and also extreme rare events and explains social strategies and modern technologies in a mathematical and provable way that everyone can check by himself and by exposing every-time the assumptions that any reasonable entity should take care of!

Obviously Applied Mathematics is such an abundant topic that a textbook of this scale can only accommodate the basis (we just scratch the surface of gigantic topics!). Readers are certainly encourage to go beyond this (see the bibliography at the end of the textbook at page 9443).

Now, those who see Applied Mathematics only as a tool (what it also is), or as the enemy of religious beliefs, or as a boring school field school, are legion. However, it is perhaps useful to recall that, as Galileo said, «*the book of nature is written in the language of mathematics*» (without wishing to do scientism!). When you go to China, you learn chinese. When you want go to the Universe you learn maths! Because maths are the language of the Universe. This is why maths are so fundamental and their are amazing as they apply to the whole Universe and across time. It is in this spirit that this textbook discusses Applied Mathematics for students in the Natural, Earth and Life sciences, as well as for all those who have an occupation related to the various subjects including philosophy or for anyone curious to learn about the involvement of science in everyday life.

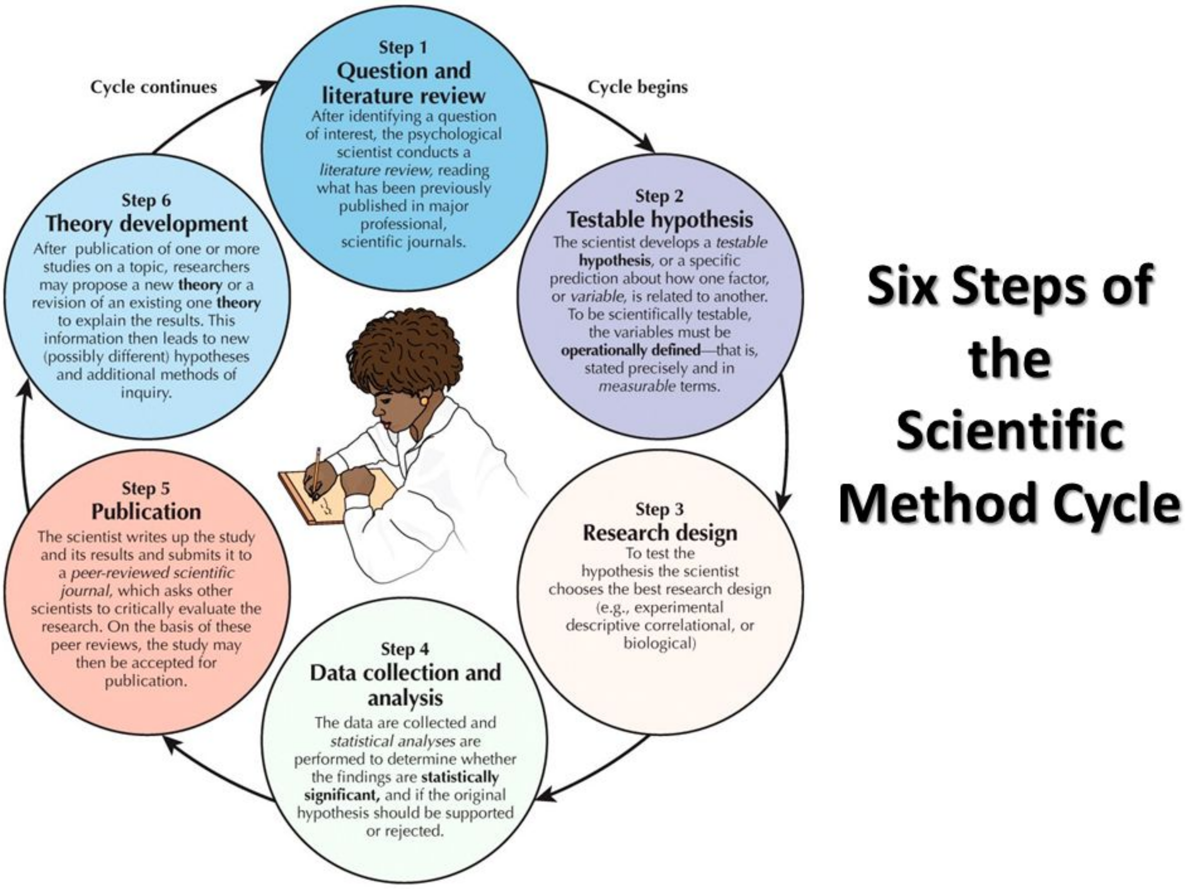
The choice to study engineering in this textbook as a branch of Applied Mathematics comes from the fact that the differences between all areas of physics (formerly known as "natural philosophy") and mathematics are so hardly notable that Fields medal (the highest award today in the field of mathematics) was awarded in 11990 (holocene calendar) to physicist Edward Witten, who used physical ideas to prove a mathematical theorem. This trend is certainly not fortuitous, because we can observe that all science, since it seeks to achieve a more detailed understanding of the subject it studies, always finish its trials in the pure mathematics (the absolute path by excellence ...). Thus, we can predict in a far future, the convergence of all the sciences (pure, exact or social) to the mathematics for the modelisation techniques (see for example the French PDF *L'explosion des mathématiques* available in the download page of the companion website).

It can sometimes seem to us difficult (due to irrational as obscure and unjustified fear of pure sciences in a large fraction of our contemporaries) to transmit the feeling of the mathematical beauty of nature, its deepest harmony and the well-oiled mechanics of the Universe, to those who know only the basics of algebra. The physicist Richard Feynman spoke a day of "two cultures": people who have and those who do not have sufficient understanding of mathematics to appreciate the scientific structure of nature. It is a pity that mathematics are necessary to deeply understand nature and that they also have a bad reputation. For the record, it is claimed that a King who asked Euclid to teach him geometry complained about its difficulty. Euclid replied, "There is no royal road". Physicists and mathematicians can not convert themselves to a different language. If you want to learn about nature, to appreciate its true value, you must understand its language. The nature is revealed only in this form and we can not be pretentious to the point of asking him to change this fact.

In the same way, no intellectual discussion will allow you to communicate with a deaf person what you really feel while listening music. Similarly, all discussion of the world remain powerless to transmit an intimate understanding of the nature of those of the "other culture". Philosophers and theologians may try to give you qualitative ideas about the Universe. The fact that the scientific method (in the full sense of the term) can not convince the World of its strengths through its iterative process (the fact that it is rewritten and rewritten and rewritten by incremental improvement as in the DMAIC Six Sigma process[3]), is perhaps the fact of the limited horizon of some people who imagine that the human or another intuitive concept, sentimental or arbitrarily is the center of the Universe (anthropocentric principle).

---

[3] DMAIC (an acronym for Define, Measure, Analyze, Improve and Control) refers to a data-driven improvement cycle used for improving, optimizing and stabilizing processes and designs. The DMAIC improvement cycle is the core tool used to drive Six Sigma projects that we will study in-deep in the section of Industrial Engineering. However, DMAIC is not exclusive to Six Sigma and can be used as the framework for other improvement applications.



Cycle continues
Step 1
Question and literature review
After identifying a question of interest, the psychological scientist conducts a *literature review,* reading what has been previously published in major professional, scientific journals.
Cycle begins
Step 2
Testable hypothesis
The scientist develops a *testable* **hypothesis**, or a specific prediction about how one factor, or *variable,* is related to another. To be scientifically testable, the variables must be **operationally defined**—that is, stated precisely and in *measurable* terms.
Step 3
Research design
To test the hypothesis the scientist chooses the best research design (e.g., experimental descriptive correlational, or biological)
Step 4
Data collection and analysis
The data are collected and *statistical analyses* are performed to determine whether the findings are **statistically significant,** and if the original hypothesis should be supported or rejected.
Step 5
Publication
The scientist writes up the study and its results and submits it to a *peer-reviewed scientific journal,* which asks other scientists to critically evaluate the research. On the basis of these peer reviews, the study may then be accepted for publication.
Step 6
Theory development
After publication of one or more studies on a topic, researchers may propose a new **theory** or a revision of an existing one **theory** to explain the results. This information then leads to new (possibly different) hypotheses and additional methods of inquiry.
Six Steps of the Scientific Method Cycle

Figure 4.2: **Scientific method cycle process (source: ?)**

Definition (#4.1.1): The "scientific method" is the iterative process that involves making reproducible observations following a robust protocol, formulating a null hypothesis statistical test to explain the observed phenomenon, predicting new phenomenons with numerical outputs based on the hypothesis, conducting experiments to be able to refute the hypothesis, analysing statistically the data collected from experiments from significant power size samples using the triple blinded method and publishing the results by respecting the scientific publication rules.

quote
4.1:40.#3

> *The internet is flooded with people who think common sense talking points are how science is done!*
>
> ?

Remark

If you are an honest scientist (the word "scientist" seems to have been used for the first time in the 118th century according to holocene calendar), the huge majority of your ideas, even good ideas (!), are going to be ruled out, not by new experiments but already by inconsistency with old experiments. This is what really makes Science very different, and what gives us an internal notion of right and wrong before new experiments. So, quite contrary to the sense that some sceptical layperson would get, the idea that you can just make up crap is wrong!

So in science we have theory, experiment, and, in the middle between them, "phenomenology". Phenomenologists are the ones who coax predictions out of theories, usually by simplifying the math and figuring out what can be measured, to which precision, and how (and, not rarely, also by whom).

> ❞ *If you are not a professional active scientist, and you disagree with scientists about Science, it's actually not a disagreement! You're just wrong!! Science is not truth. Science is finding the evidence. When science changes its opinion, it didn't lie to you. It learned more!* ❞
>
> ?

quote 4.1:41.#4

4.1.1 Motivation and goals

The main purpose of this textbook is to make Modern Science known throughout the world so that all human beings can understand and know the origins and mechanisms of Nature around them.

Of course, in order to share this mathematical knowledge, it may seem paradoxical to increase, with our work, the long list of books already available in libraries, in commerce and on the Internet. Nevertheless, I must be able to present arguments that justifies the creation of such a textbook (and its associated website) as compared to textbooks such as that of Feynman ($\sim 1,500$ pages), Landau ($\sim 3,000$ pages) or Bourbaki ($\sim 8,200$ pages) and Wikipedia/Wolfram webpages themselves or Khan Academy videos or OpenStax PDFs ($\sim 5,500$ pages) or even the *Enzyklopädie der mathematischen Wissenschaften* ($\sim 20,000$ pages). So what do I think I can add to such a wealth of material?

1. The great pleasure that we take to write this textbook ("keep the hand" and improve our skills) and have a detailed high quality compendium of tools for our customers and our students (and also all those around the World) for free.
2. The passion for sharing knowledge for free (battle again "copyright madness" (RIP Aaron Swartz!)) and without frontiers with a tool of quality as LaTeX (at the opposite of Wikipedia that mixes LaTeX and normal text and the awful and shameful content of Khan Academy[4]).
3. Support free scientific education, critical thinking and evidence-based understanding of the natural World. Furthermore it is clear that there is an undeserved appetite for people to understand and this textbook has been written for this purpose (we will for example

---

[4] OpenStax has good undergraduate PDF - especially the example in their books - but there are between 40-60% of missing proofs and the table of contents of their PDF and also the Index are not interactive... and major issue...: the content is limited only to undergraduate subjects

introduce the scientific definition of a vaccine, we will deal mathematically with some of the fallacious arguments of flat earthers, we will also prove mathematically why it is normal not to see the stars in many photos or videos taken in space, we we will prove why the Big Bang (i.e. cosmic inflation theory) at the contrary to an urban legend is neither an explosion nor a singularity and was not discovered by G. Lemaître, we will prove mathematically that the Universe can emerge spontaneously by disintegration of the quantum vacuum, that the emergence of life from non-life is only a question of probabilities, etc.).

> ❞ *We don't debunk lies to convince the liars, we debunk lies to educate other people that lies aren't going unchallenged!* ❞

4. Helping defenceless people who are being dragged into false dichotomous beliefs by oversimplified false rhetorical statements or claims to acquire a certain level of critical method and investigation techniques.

5. Write a modern 3rd millennial version of the "Almagest" hence the name "Opera Magistris" that means in English "Major Work".

6. Because we can't wait as there are places in the world where the absence of teaching modern science and its methodology takes peoples to have believes that bring them to some dangerous and obscure paths.

7. We want to offer Applied Mathematics in an enjoyable and easy-to-learn manner ("keep it simple and stupid" at the opposite of the 9 Landau's graduate level books), because we think that Applied Mathematics change the way we understand the Universe.

8. This textbook was first written in French before (in year 12001 according to holocene calendar) that the French version of Wikipedia had good mathematical content and long before Khan Academy or OpenStax did even exist.

9. The quick updates/corrections opportunities to the last scientific discoveries (at the opposite of Khan Academy) and collaborations of a free e-book (with associated effective search tools) without having topics that disappears (at the opposite of Wikipedia).

10. The content depending on readers requests/comments and on our interests (at the opposite of Khan Academy, OpenStax or Landau textbooks)!

11. At the opposite of Scientific publications (PRL or other similar) that sucks because don't give detailed proofs and sometimes turn in an infinite loop of references.

12. The access to LaTeX sources to everybody so nobody need to reinvent the wheel and loose hundred or thousand of hours on redaction instead of innovation (at the opposite of Landau, Feynman and Bourbaki textbooks)!

13. Rigorous presentation with simplified detailed proofs of all presented concepts (at the opposite of Wikipedia, Khan Academy and OpenStax that focus only of the mathematical proofs of undergraduate concepts).

14. The presentation of many advanced and detailed mathematical tools used in business and R&D keeping in mind that the mathematical language seems eternal and to be one of the only common denominator between all countries in the World.

15. The opportunity for students and teachers to reuse content by copy/paste (at the opposite of Landau, Feynman and Bourbaki textbooks)!.
16. Constant and fixed notation (at the opposite of Wikipedia, Khan Academy and OpenStax) throughout the textbook, for mathematical operators, a clear language on all topics (3.C. criterion: clear, complete and concise) and focus on the basics to make an important pedagogical work on the subjects (at the opposite of Landau's textbooks).
17. Gather as much information about pure and exact sciences in one electronic (portable), homogeneous and rigorous textbook (but that don't go as far as Landau's textbooks).
18. Release from all pseudo-truths, only truths[5] that can be proven mathematically with detailed reasoning.
19. Benefit from the development of teaching methods that use the Internet to search for the solution of mathematical problems.
20. The dramatic improvement of automatic translation software and computing power that will make of this textbook, at least we hope, a reference in the fields of sciences.
21. A PDF is better than a website as first all people that use the Internet since 11990 (holocene calendar) know that the huge majority of website disappear after ten years and secondly it is well known that some countries block Wikipedia and other knowledge website to keep their population in the ignorance (and block a PDF that can be shared in a e-mail is much more difficult).
22. and... because Applied Mathematics are beautiful and especially when written in LaTeX and illustrated (at the opposite of Landau or Bourbaki textbooks whose illustrations and equation rendering quality are quite old and poor).

And also ... I think that the results of individual research are the property of humanity and should be available to all those who explore anywhere the phenomena of nature. In this way the work of each benefit to all, and that is for all humanity that our knowledge cumulates and this is the trend that allows Internet.

I do not hide that my contribution is limited largely to this day to that of a collector who gleans his information in the works of masters or publications or from anonymous web pages and who completes and argues developments and improved them when this is possible. Therefore some of the material in this textbook is original, and some comes from primary literature. However the vast majority of what we wrote is a rephrasing of results presented in the existing vast library of some (rare) fantastic textbooks. For those who would accuse me of plagiarism, they should think on the fact that the theorems presented in most non-free textbooks and commercially available have been discovered and written by their predecessors and their own personal contribution was also made, like mine, to put all this information in a clear and modern form a few hundred years later. In addition, it can be seen as doubtful that we ask to pay for access to a culture that is certainly the only truly valid and fair one in this world and where there is no patent or intellectual property rights.

---

[5] Here the word "truth" must not be taken in the sense of "absolute truth" that anyway doesn't exist in experimental science! But only as "something that works in a very reliable way as far as we know"!

quote
4.1:44.#5

> *If you steal from one author, it's plagiarism; if you steal from many, it's research!*
>
> Wilson Mizner

This textbook also reflects my own intellectual limitations. Although I try to study as much science and math fields as possible, it is impossible to master them all. This textbook shows clearly only my own interests and experiences as consultant, but also my strengths and my weaknesses. I am responsible for the selection of inputs and, of course, of possible errors and imperfections.

After attempting a strict (linear) order of presentation of the subject, I decided to arrange this textbook in a more pedagogical (thematic) way and always with practical examples o applications. It is in my opinion very difficult to speak of so vast subject in a purely mathematical order in only one human life, that is to say, when the concepts are introduced one by one, from those already known (where each theory, operator, tools, etc.. would not appear before its definition). Such a plan would require cutting the book, in pieces that are not more thematic. So I decided to present things in a logical order and not in order of need. Thus the reader will encounter, as the editor himself, to the extreme complexity of the subject.

The consequences of this choice are the following:

1. Sometimes it will necessary to admit certain concepts, even to understand later.
2. It will probably be necessary for the reader to go at least twice throughout the book. At the first reading, we apprehend the essential and at the second reading, we understand the details (I congratulate this who understand all the subtleties the first time).
3. You must accept the fact that some topics are repeated and that there are many cross-references and complementary remarks.

Some know that for every theorem and mathematical model, there are almost always several methods of proofs. I've always tried to choose the one that seemed the most simple (e.g. in relativity and quantum physics there is the algebraic and matrix formalism). The objective is to arrive at the same result anyway.

This textbook being in its draft version, it necessarily has lacks on convergence controls, on continuity, grammar and others... (which will horrify some readers and mathematicians ...)! However, I have avoided (or, otherwise, I indicate it) the usual approximations of physics and the use of dimensional analysis, by using it as little as possible. I also try to avoid as much as possible subjects with mathematical tools that have not previously been presented and demonstrated rigorously.

Finally, this presentation, that can still be improved, is not an absolute reference and contains errors. Any comment is welcome. I shall endeavour, as far as possible, to correct the weaknesses and make the necessary changes as soon as possible.

However, while mathematics is accurate and indisputable, theoretical physics (its models), is still interpreted in the common vocabulary (but not in the mathematical vocabulary) and its conclusions all relative. I can only advise, when you read this textbook, to read by for yourself and not to be subjected to outside influences. You must have a very (very) critical mind, take nothing for granted and question everything without hesitation. In addition, the keyword of good scientist should be: "Doubt, doubt, doubt ... doubt still, and always checks.". We also recall that "nothing that we can see, hear, smell, touch or taste, is what it seems to be", therefore do not rely on your daily experience to draw hasty conclusions, be critical, Cartesian, rational and rigorous in your development, reasoning and conclusions!

Remark

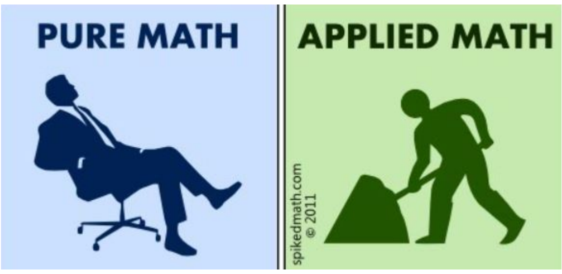
One of the causes of anti-intellectualism probably lies actually in the inability of educational institutions to inculcate critical thinking at high-school. In particular universities, unable to develop critical thinking of their students. The Internet and its amalgamation of true and false also have their part of responsibility. In addition, some experts increase the problem by speaking publicly on issues outside their area of expertise!!!!

I want to say to those who would try to find themselves the results of some developments of this textbook, do not worry if they do not success or if they doubt about their competences because of the time spent solving an equation or problem: some theories that seem obvious or easy today, have sometimes needed several weeks, months, even years, to be developed by mathematicians or leading physicists in the past!

I also tried to ensure that this textbook is pleasing to the eye and to read through.

Finally, I have chosen to write this work in the first person plural form: "we". Indeed, the mathematical physics is not a science that has been made or has evolve through individual work but with intensive collaboration between people connected by the same passion and desire of knowledge. Thus, by making use of "we", I would like to pay tribute to the dead and missing scientists, to contemporary and future researchers for the work they will perform in order to approach the truth[6] and wisdom.

I am happy to make this precious work available to you, and I hope that you will enjoy reading it a little every day!



---

[6] It is clear from the above discussion that scientific research does not and can not lead to a knowledge of nature that is completely free from error. Rather it leads and is able to lead only to an unending process in which the degree of truth in our knowledge is continually increasing. Thus, with the further progress of science into new domains, it becomes possible for us to define the errors in older laws in more and more detail and in more and more respects, and in this way to delimit the domains of validity of these laws more precisely and more nearly completely.

quote
4.1:45.#6

> *Truth is a word that oddly is used most by those who spread lies, that they themselves know to be lies!*
>
> ?

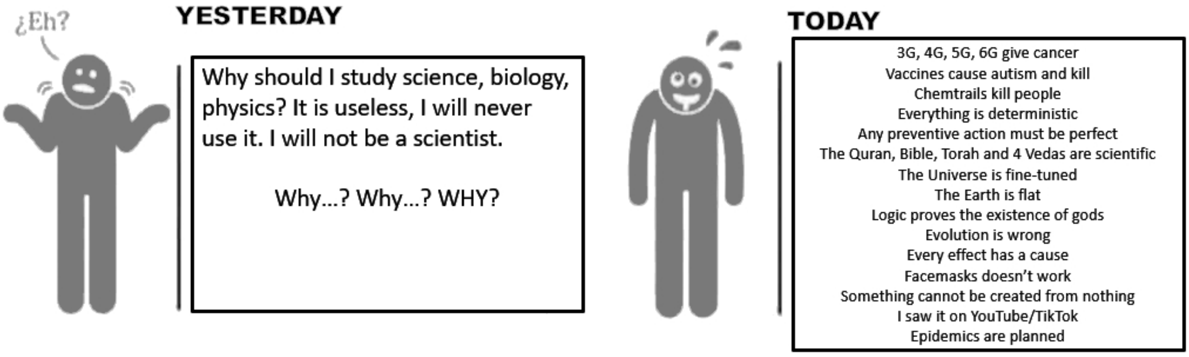
4.1.2 Who this textbook is intended for

This textbook is intended for anyone who is curious about Science and wants to learn more about the Natural world, its origin and mechanisms. It is written in a clear and concise way, making it easy to understand even if you have no prior knowledge of Science. Whether you are a student, a teacher, a hobbyist, or just a casual reader, this textbook will provide you with an engaging and accessible introduction to the fundamental concepts and methods of Science. You will explore detailed proofs from kindergarten level to PhD level on topics such as mathematics, probabilities, physics, engineering, management, finance, chemistry, biology, astronomy, geology, ecology, and more, using real life examples. You will also discover how science relates to everyday life and how it can help you solve problems and make informed decisions and to not be manipulated by the lies of religions/sects and charlatans. this textbook is not a comprehensive textbook, but rather a guide to spark your interest and inspire you to further your scientific knowledge and skills. By reading this textbook, you will develop a scientific mindset and a lifelong passion for learning.

Here are some specific examples of who might find this textbook useful:

- Students in any grades who are learning about science
- Teachers who are looking for a free resource to use in their classrooms
- Consultant who need to provide an unique rigorous source to their customers
- Adults who are interested in learning more about science
- Anyone who is curious about the world around them

This textbook is designed to be flexible and adaptable to your needs and preferences. You can use it as a self-study guide, a reference book, a supplement to your school curriculum, or a source of inspiration for further exploration.



¿Eh?
YESTERDAY
Why should I study science, biology, physics? It is useless, I will never use it. I will not be a scientist.
Why...? Why...? WHY?
TODAY
3G, 4G, 5G, 6G give cancer
Vaccines cause autism and kill
Chemtrails kill people
Everything is deterministic
Any preventive action must be perfect
The Quran, Bible, Torah and 4 Vedas are scientific
The Universe is fine-tuned
The Earth is flat
Logic proves the existence of gods
Evolution is wrong
Every effect has a cause
Facemasks doesn't work
Something cannot be created from nothing
I saw it on YouTube/TikTok
Epidemics are planned

By reading this textbook, on the philosophical point of view, you will typically learn and be exposed to the mathematical proofs and scientific experimental evidence of the following topics:

- Why there is something rather than nothing
- Why the Big Bang isn't an explosion that started at a point
- Why there are a dozens of different types of logics build on different axioms
- Where morality comes from
- That consciousness is only chemical
- Why mathematics are build in such a way to describe to real world so well
- Where does information comes from
- Where particles, atoms, stars, planets and galaxies are formed
- How did life arise from non-life
- Why the our universe isn't fine-tuned for life
- That the purpose of life is to follow the arrow of entropy
- Why time is an illusion in the framework of the Wheeler-DeWitt universe model
- Why everything around you is only a problem of probabilities
- Why scientists don't trust their intuition or reason but instead follow the evidence

4.1.3 How is this textbook structured

This science textbook is structured in a way that gradually increases in complexity. The first few chapters introduce basic concepts and principles, and then the later chapters build on these concepts to explore more advanced topics. The textbook is divided into 12 parts, each covering a major branch of science: mathematics, physics, computing, social science, finance and engineering. Each part consists of several chapters that introduce the key concepts, principles, and phenomena of that branch.

This structure allows readers to learn at their own pace. If you are new to science, you can start with the early chapters and then move on to the later chapters as you become more comfortable with the material. The chapters are organized in a quite logical sequence, building on the previous ones and preparing you for the next ones when possible.

Each chapter begins with an overview of the topic that will be covered. This overview provides a framework for understanding the material that follows. The chapter then proceeds to discuss the topic in more detail, using clear and concise language.

You can follow the textbook from start to finish, or you can choose the topics that interest you the most and skip the ones that you are already familiar with. The textbook also provides cross-references, glossaries, appendices, and indexes that help you navigate the textbook and find the information you need.

To help you understand the material, the textbook includes a variety of features, such as:

- The textbook includes many illustrations to help you visualize the concepts being discussed
- The textbook includes examples to help you understand how the concepts being discussed apply to the real world

I hope this helps you understand how this textbook is structured.

4.2. Methods

SCIENCE is the set of all systematic efforts (scrupulous observations and plausible assumptions until the evidence of the contrary) to acquire knowledge about our environment, to organize and synthesize them into testable laws and theories, whose main purpose is to explain the "how" of things (and NOT the why!) often by a four-step approach:

- What do we have?
- Where will we go?
- What is our goal?
- Does it fit the data?

Scientists have to submit their ideas and results to independent verification and replication of their peers[7] ("peer review"). They must abandon or modify their conclusions when confronted with more complete or different evidences. The credibility of Science is based therefore on this self-correcting mechanism and this is what still makes in the 121st century (holocene calendar) that Science is not the best tool (as we do not know what will exist in the future...) but is has been proven as being the best investigation method for truth (i.e. not the "philosophical truth", but the "truth" as the best explanation at our actual level of knowledge) in comparison for all other actual existing methods or beliefs. The history of science shows that this system works very well compared to all the others. In each area, progress has been spectacular. However, the system sometimes fails and has also to be corrected before small drifts accumulate.

The downside is that scientists are humans. They have the imperfections of all humans, and especially, vanity, pride, anger and conceit. Nowadays, it happens that many people working on the same topic for a given time develop a common faith and believe[8] they hold the truth. The leader of the faith is the Pope and distils his opinion. The Pope that plays the game, takes his miter and his pilgrim's staff to evangelize his fellow heretics. Until then, this makes smile. But, as in real religions, they are sometimes annoying to want to expand their opinion to those who do not believe. Some of these "churches" do not hesitate to behave like the Inquisition. Those who dare to express a different opinion are burned at every opportunity, during conferences, or at their place of work. Some young researchers, uninspired, prefer to convert to the dominant religion, to become clerics faster rather than innovative researchers or even iconoclasts. The great Pope write his Bible to disseminate his ideas, imposes it to read to students and newcomers. He formats then the thought of younger generations and ensures his throne. This is a medieval attitude that can block progress. Some Popes go so far that they believe be the pope in their specialization field automatically gives them the same throne in all other areas...

---

[7] Although peer review is an essential tool for maintaining the quality of scientific research, it is obviously not without flaws since it is performed by humans with all their usual biases. However, it remains the method with the lowest error rate to date.

[8] There are multiple definitions of "faith". Wikipedia gives: « *Confidence or trust in a person, thing, or concept. Belief in God or in the doctrines or teachings of religion.* ». The christian bible (Hebrew 11:1) gives: « *Now faith is confidence in what we hope for and assurance about what do not see.* »

This warning, and the reminders that will follow, must serve the scientist or any reader to ask himself by making good use of what we consider today as the good working/reasoning practices (we will discuss the principles of the Descartes method more below) to solve problems or develop theoretical models. And we do not use the models to build up some metaphysical system. We use the models to predict the outcomes of other measurements and to aid us in putting these to practical use!

For this purpose, here is a summary table that provides the steps that should be followed by a scientist who works in mathematics or theoretical physics (for definitions, see just below):

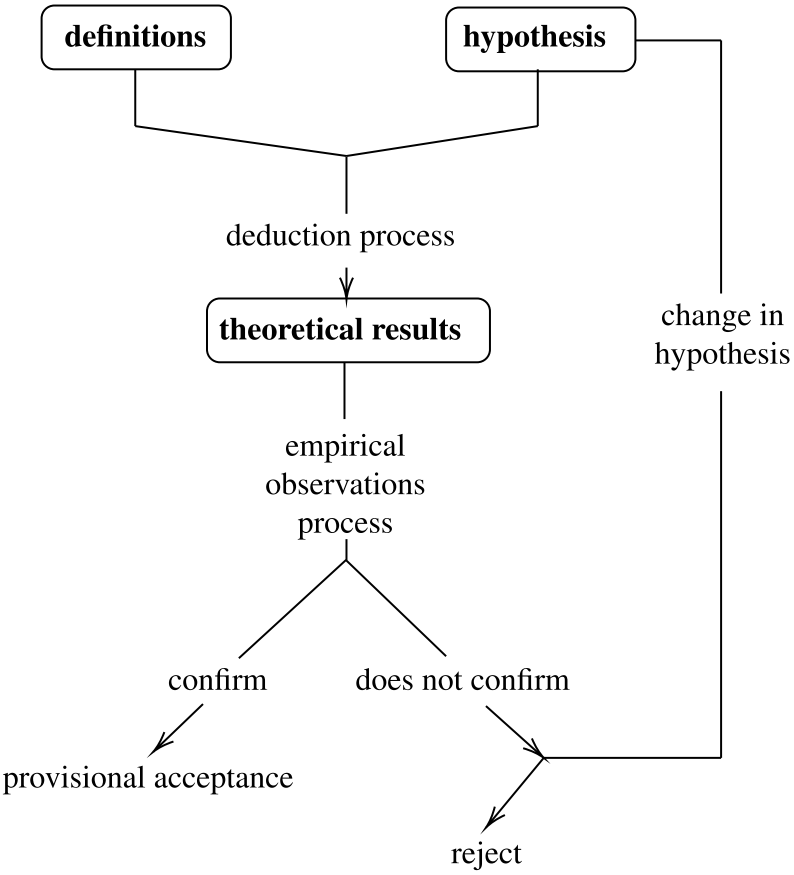
Mathematics	Physics
1. Expose formally or in common language the "hypothesis", the "conjecture" the "property" to prove (hypothesis are denoted H1., H2., etc. the conjectures CJ1., CJ2., etc. and the properties P1., P2., etc.).	**1.** Expose correctly in a formal or common language all the details of the "problems" to solve (problems are denoted P1., P2., etc.) and defines the vocabulary and notations rigorously.
2. Define the "axioms" (non-demonstrable, independent and non-contradictory) that will give the starting points and establish restrictions on the developments (the axioms are denoted A1., A2., etc.)[9]. In the same vein, the mathematicians define the specialized vocabulary related to mathematical operators which will be denoted by D1., D2., etc.	**2.** Define (or state) the "postulates" or "principles" or the "hypothesis" and "assumptions" (supposedly unprovable but supported by datas!) that will give the starting point and establish restrictions on the developments (typically, assumptions and principles are denoted P1., P2., etc. and assumptions H1., H2., etc. trying to avoid the notation confusion between postulates and principles)[10]
3. Once the Axioms laid, pull directly "lemmas" or "properties" whose validity follows directly and prepare the development of theorem supposed to validate departure hypothesis or conjectures (lemmas being denoted L1., L2., etc. and properties P1., P2., etc.).	**3.** Once the "theoretical model" (not to be confuse with the word "theory"...!) developed, check equations units for possible errors in the developments (such checks being denoted VA1., VA2., etc.).
4. Once the "theorems" (noted T1., T2., etc.) proved conclude on "consequences" (denoted C1., C2., etc.) and even properties (denoted P1., P2., etc.).	**4.** Search for borderline cases (including "singularities") of the model to verify its validity/behaviour intuitively (these borderline controls are denoted CL1., CL2., etc.).
5. Test the strength (robustness) or usefulness of the conjectures or hypothesis by proving the reciprocal of the theorem or by comparing them with other examples of mathematical well-know theories to see if form together a coherent structure (examples being denoted E1., E2., etc.).	**5.** Experimentally test the theoretical model obtained and submit work to compare with other independent research teams. The new model should provide experimental results and new never observed one (predictions to falsify). If the model is validated beyond reasonable doubt then it can get the official status of "theory".
6. Possible remarks may be shown in a hierarchically structured order and denoted R1., R2., etc.	**6.** Possible remarks may be shown in a hierarchically structured order and denoted R1., R2., etc.

Table 4.1: **Methodology for Maths & Physics developments**

Remark

The fact that a question can be phrased in a grammatically correct English sentence doesn't make it meaningful, or entitle it to our serious attention. Nor, the fact that a word exist in the dictionary (like the word "soul") make it real...

Proceed as in the above table is a possible workflow basis for people active in the field in mathematics or physics, or for any individual that wants to follow a rigorous critical thinking process[11]. Obviously, proceed cleanly and traditionally as above takes a little or much more time than doing things no matter how (this is why most teachers do not follow these rules, as they would otherwise not have enough time to cover their entire course program) and this is one of the reasons why science takes a majority of people outside of their comfort zone (as most people are looking to fix problems and interrogations in less than a few dozens of minutes).



It must also be known to the reader that we insist on the fact that real scientists should no have emotions behind the subjects they study or speak about. They have to only use evidence (facts based on data, peer review, reproducible experiences, consensus of scientific community) rather

---

[9] Sometimes "properties", "conditions" and "axioms" are confused while the concept of axiom is much more accurate and profound.

[10] The reader should not forget, however, that the validity of a model is not dependent on the realism of its assumptions but on the conformity of its implications with reality.

[11] To educate and exercise yourself or students on the topic of critical thinking we strongly recommend [432] and critical thinking tests like the Ennis-Weir test (free-writing test in which the test-taker evaluates, paragraph by paragraph, a given reasoned case) or the California Critical Thinking Disposition Inventory (CCTDI) that measures dispositions to use critical thinking skills like the Watson-Glaser Critical Thinking Appraisal (WGCTA).

than emotional, biased[12], subjective educational individual analysis that are not data driven. Obviously we may question the assumption that the used sensory probes detect something real or not? But professional scientists don't care about such a philosophical question. The only thing that matters (putting a part the fun of it...) is that these sensory probes give reliable, useful and consistent measures to test models that will help to build new tools for humanity!

Definitions (#4.2.2):

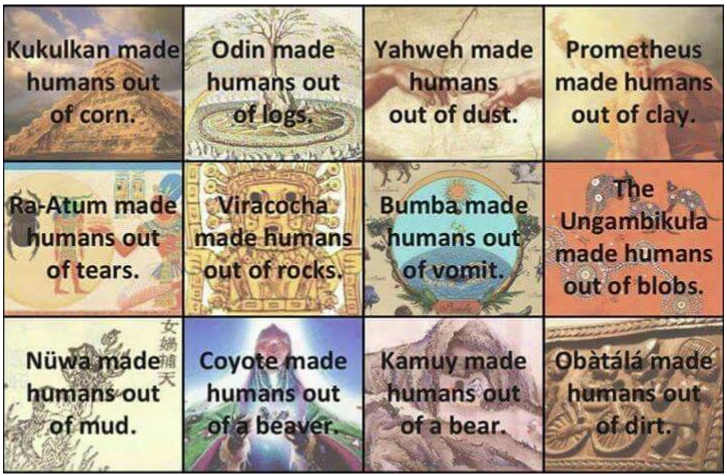
D1. The "reality" is the total set of phenomena that can be observed, measured, and tested, and whose existence is supported by public, reproducible empirical evidence.

D2. An "ontological fact" concerns the fundamental nature of reality and what exists, assumed to be independent of human perception and instruments.

D3. An "epistemological fact" relates to how we come to know or understand something - our knowledge, methods, and justifications.

> *What we observe is not Nature in itself but Nature exposed to our method of investigation.*
>
> Werner Heisenberg

quote 4.2:53.#7



Kukulkan made humans out of corn.
Odin made humans out of logs.
Yahweh made humans out of dust.
Prometheus made humans out of clay.
Ra-Atum made humans out of tears.
Viracocha made humans out of rocks.
Bumba made humans out of vomit.
The Ungambikula made humans out of blobs.
Nüwa made humans out of mud.
Coyote made humans out of a beaver.
Kamuy made humans out of a bear.
Obàtálá made humans out of dirt.

Figure 4.3: **An example of absence of consensus in a small sample of religions**

> *Science doesn't set out to refute religions; science sets out to discover what is true. Religions are just collateral damage!*
>
> ?

quote 4.2:53.#8

---

[12] Among all major biases that we will introduce later, the Confirmation Bias - the tendency to search for, interpret, favour, and recall information that confirms or supports one's prior personal beliefs or values - is very likely the most common by scientifically illiterate people.

Notice also a funny shape of scientific 10 commandments:

1. The phenomena you will observe
   And never measures you will falsify
   (attention to the confirmation bias[13]!)
2. Hypothesis you will proposed
   That with experiment you will test
3. The experiment precisely you will describe and the data and algorithms you will provide
   Because your colleague will reproduce it
   (attention to the narrative discipline trap: the facts will be fitted to the desired results)
4. With your results
   A theory you will build
5. Parsimony you will use
   And the simplest hypothesis you will retain
6. Ultimate truth will never be (epistemic humility)
   And always you will search for the truth
7. From a non-refutable thesis you will refrain
   Because outside of the science it will remain
8. All failures will be like a success
   Because science can confirm but also invalidate
9. My authority I will not use (authority bias)
   To bias people opinions in fields where I have no proven expertise
10. The Archimedean Oath and the Scientific Publication Rules I will respect
    As science must be transparent and responsible

quote 4.2:54.#9

> ❞ *Science knows it doesn't know everything, otherwise it would stop.* ❞
>
> Dara Ó Brian

---

[13] It's very strongly advised to read our introduction to cognitive biases in the section of Decision Theory page 7381

Caution! It is very easy to make new physical theories by just aligning words. This is named "philosophy" or "rhetoric" and the Greeks thought of the atoms in this method. This can lead with a lot of luck to a true theory. Against it is much more difficult to make a "predictive theory", that is to say with equations that predict the outcome of an experiment (all physical theories must posit a correspondence between their mathematical apparatus and the physical world that they are attempting to describe).

Moreover many philosophers reinvent arguments physicists have long known to be wrong. We have heard philosophers worry about paradoxes physicists solved ages ago, and we have heard philosophers deduce how natural laws should be while ignoring how natural laws are. In short, there are unfortunately many philosophers who don't notice when they are out of their depth. The same can be said of physicists, though. Some physicists draw on philosophical arguments more frequently than they like to admit. It's easy enough however for us to discard philosophy as useful - because it is useless.

> ” *Science doesn't know everything, religion doesn't know anything!* ”
>
> L. Aron Nelson

quote
4.2:55.#10

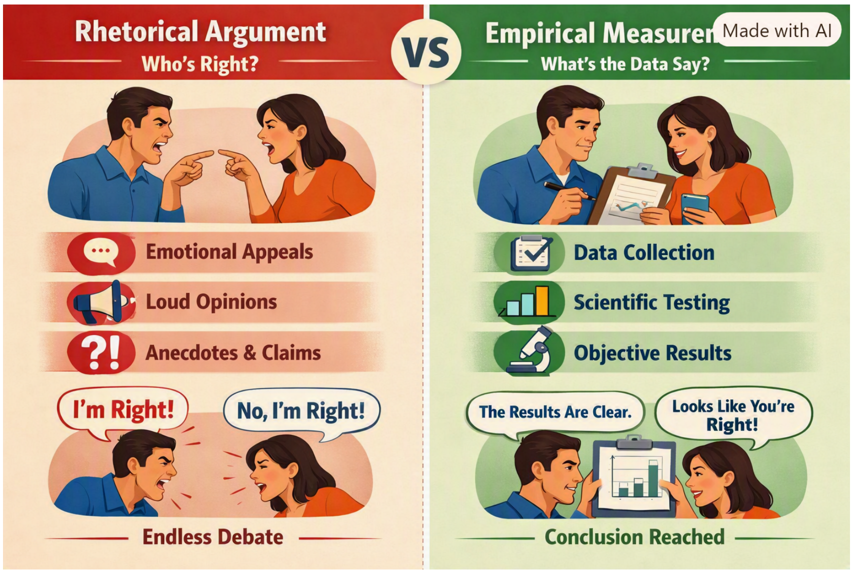
Remark

What separates mathematics and physics is that in mathematics, the hypothesis is always true. Mathematical discourse is not a proof of an external seeking truth, but a target of consistency. What should be correct is just the reasoning.

> ” *When people say "The reason you can't trust science is that scientists used to say <thing that turned out be wrong> but now they say <different thing>", they are actually explaining why science works so well!* ”
>
> Matt Blaze

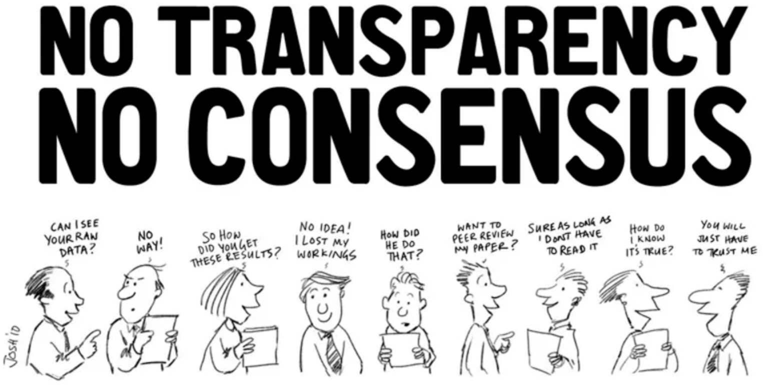
quote
4.2:55.#11

When these rules are not respected, we speak of "scientific fraud" or of "intellectual fraud" (which often leads to being fired from his job but unfortunately we still not retired the diplomas when it happens). In general, scientific fraud itself comes in four main forms: plagiarism, fabrication of data and alteration of results unfavourable to the hypothesis, the omission of clear working hypotheses and collected datas, fallacious and biased arguments (remember that especially a rhetorical argument that isn't backed up by experimental evidence has no interest for professional scientists!).



Rhetorical Argument
Who's Right?
VS
Empirical Measurement
What's the Data Say?
Made with AI
Emotional Appeals
Loud Opinions
Anecdotes & Claims
I'm Right!
No, I'm Right!
Endless Debate
Data Collection
Scientific Testing
Objective Results
The Results Are Clear.
Looks Like You're Right!
Conclusion Reached

To these frauds we can also add behaviours that pose problems regarding to the quality of work or more specifically to ethics, such as submitting for example several times the same publication with only a few modifications, the omission of conflict of interest (financial, religious, political), the dangerous experiments, the non-conservation of primary data, etc.



NO TRANSPARENCY
NO CONSENSUS
CAN I SEE YOUR RAW DATA?
NO WAY!
SO HOW DID YOU GET THESE RESULTS?
NO IDEA! I LOST MY WORKINGS
HOW DID HE DO THAT?
WANT TO PEER REVIEW MY PAPER?
SURE AS LONG AS I DON'T HAVE TO READ IT
HOW DO I KNOW IT'S TRUE?
YOU WILL JUST HAVE TO TRUST ME
JOSH 10

Figure 4.4: Source: http://cartoonsbyjosh.co.uk

4.2.1 Descartes' Method

Now we present the four principles of the Descartes' method which, as remind, is considered as the first scientist in history by his method of analysis:

P1. Never accept anything as true that I obviously knew to be such. That is to say, carefully avoid precipitation and to understand nothing more in my judgements than what would appear so clearly and distinctly to my mind, that I had no occasion to doubt.

P2. Divide each of the difficulties I have to examine into as many parts as possible (scrupulous observations and plausible hypothesis until evidence of the opposite), and that would be required to resolve them in the best way.

P3. Driving my thoughts in order, beginning with the simplest objects and easiest to know, to go up gradually by degrees to the knowledge of the most compounds, and even assuming the order between those who not naturally precede each other.

P4. Make everywhere so complete enumerations and so general reviews, that I'm sure not to omit anything.

> ”” *The Art and Science of asking questions is the source of all Knowledge.* ””
>
> Thomas Berger

quote 4.2:57.#12

Nullius in Verba

Nullius in verba (Latin for "on the word of no one" or "take nobody's word for it") is the motto of the Royal Society. It is an expression of the determination of Fellows to withstand the domination of authority and to verify all statements by an appeal to facts determined by reproducible experiments and by cautious scientific peer review[14].

> ”” *You are entitled to your opinion. But you are not entitled to your own facts.* ””
>
> Daniel Patrick Moynihan

quote 4.2:57.#13

---

[14] The process of peer review generally applies to journal articles, but it is possible for a textbook to be peer reviewed as well. Although many textbooks go through some sort of editorial or review process, there is not an easy method for determining whether a textbook is peer reviewed. One method for locating peer reviewed textbooks is to take a look at textbook publications from university presses. Textbooks published by university presses almost always go through a process of peer review. Textbooks from university presses are typically written by faculty members are who are under immense pressure to produce authoritative scholarly literature. The process of peer review for university presses typically involves two or three independent referees who will initially review the manuscript. If the manuscript receives positive review, the university press will send it to their editorial board, who are all faculty members, for final review.

4.2.1.1 Blind studies

Scientific experiments[15] are designed to determine facts about our world using either "retrospective studies" based on the search of correlations by exploiting existing databases (hence looks backwards) or "prospective studies[16]" based on the search of causalities using controlled/randomized/double-blinded experiments (respectively frequently abbreviated RCT or RCDBT where the "T" stand for "Trial" instead of using the word "Experiment" or "Study"). But in complicated analyses, there's a risk that researchers will unintentionally skew results to match what they were expecting to find. To reduce or eliminate this potential bias, scientists apply a method known as "blind analysis".

Phenomenon	**Causal diagram**	**Structural equations**	**Description**
Causation		$y = f(a)$	A causes Y.
Mediation (full)		$m = f_1(a)$ $y = f_2(m)$	The effect of A on Y is fully mediated by M.
Mediation (partial)		$m = f_1(a)$ $y = f_2(a, m)$	The effect of A on Y is partially mediated by M.
Confounding		$a = f_1(c)$ $y = f_2(a, c)$	C is a common cause (or confounder) of A and Y.
Conditioning[1]		$a = f_1(c)$ $y = f_2(a, c)$	Analysis or study design is conditional on C (i.e. controlling for C, adjusting for C, etc.).
Collider		$c = f(a, y)$	C is a collider of A and Y, i.e. conditioning on C would induce a spurious association between A and Y.
Collider bias[1]		$c = f_1(a, u)$ $y = f_2(u)$	Y is independent of A, but conditioning on the collider C creates a spurious association between A and U (dashed line), opening a back-door path between A and Y.
Instrumental variable		$y = f_1(a, u)$ $a = f_2(z, u)$	Z is an instrumental variable for the exposure A, i.e. the association between Z and Y can be used to derive an estimate of the effect of A on Y.
Feedback loop		$a_2 = f_1(a_1, y_1)$ $a_3 = f_2(a_2, y_2)$ $y_2 = f_3(a_1, y_1)$ $y_3 = f_4(a_2, y_2)$	Example of a cyclical process or feedback loop, where the exposure A is affected by past values of the outcome Y and vice versa.

[1] Note that conditioning on the variable C is only represented in the causal diagram, not in the structural equations.
A: exposure. C: confounder or collider. M: mediator. U: unmeasured confounder. Y: outcome. Z: instrumental variable.

Figure 4.5: **Most common types of causal relationships in Science (source: [275])**

---

[15] This text is a copy/paste of an article written by Manuel Gnida at `http://www.symmetrymagazine.org/article/the-facts-and-nothing-but-the-facts`

[16] Prospective studies have usually fewer potential sources of bias and confounding than retrospective studies.

Definition (#4.2.3): A "randomized controlled trial" (RCT) is a form of scientific experiment used to neutralize factors not under direct experimental control by randomly allocating participants among compared treatments. This random allocation achieve sufficient conversion of confounding factors (confounding factors are those that may compete with the exposure of interest in explaining the effect of a treatment) as white noise to deliver a useful comparison of the treatments study.

Blind studies are probably best known from their use in clinical drug trials[17] (the term "triple-blinding" sometimes refers to this), in which patients are kept in the dark about - or blind to - whether they're receiving an actual drug or a placebo[19] or standard of care (indeed dummy pills, with no pharmacological activity at all, demonstrably improve health at a low statistical level of significance that is why double-blinded drug trials must use placebos or standard of care as controls to neutralize the placebo effect and permit the blinding of the treatment) but also the doctors themselves (to minimize behavioural bias) and the people who collects the data (to minimize the corruption), we speak then of "double-blinded randomised placebo controlled trial". This approach helps researchers judge whether their results stem from the treatment itself or from the patients' belief that they are receiving it. But the method is also use in Gastronomy tasting or in forensic laboratories as well.

Particle physicists and astrophysicists do blind studies, too (see [299])!!! The approach is particularly valuable when scientists search for extremely small effects hidden among background noise that point to the existence of something new, not accounted for in the current model. Examples include the much-publicized discoveries of the Higgs boson by experiments at CERN's Large Hadron Collider[20] (a double-blind data under wraps was done by the DZero and CDF groups of the Higgs experiment) and of gravitational waves by the Advanced LIGO detector.

«*Scientific analyses are iterative processes, in which we make a series of small adjustments to theoretical models until the models accurately describe the experimental data.*» says Elisabeth Krause, a postdoc at the Kavli Institute for Particle Astrophysics and Cosmology, which is jointly operated by Stanford University and the Department of Energy's SLAC National Accelerator Laboratory. «*At each step of an analysis, there is the danger that prior knowledge guides the way we make adjustments. Blind analyses help us make independent and better decisions*».

Return on experience (REX) shows as expected that blind analyses need to be designed individually for each experiment. The way the blinding is done needs to leave researchers with enough information to allow a meaningful analysis, and it depends on the type of data coming out of a specific experiment.

---

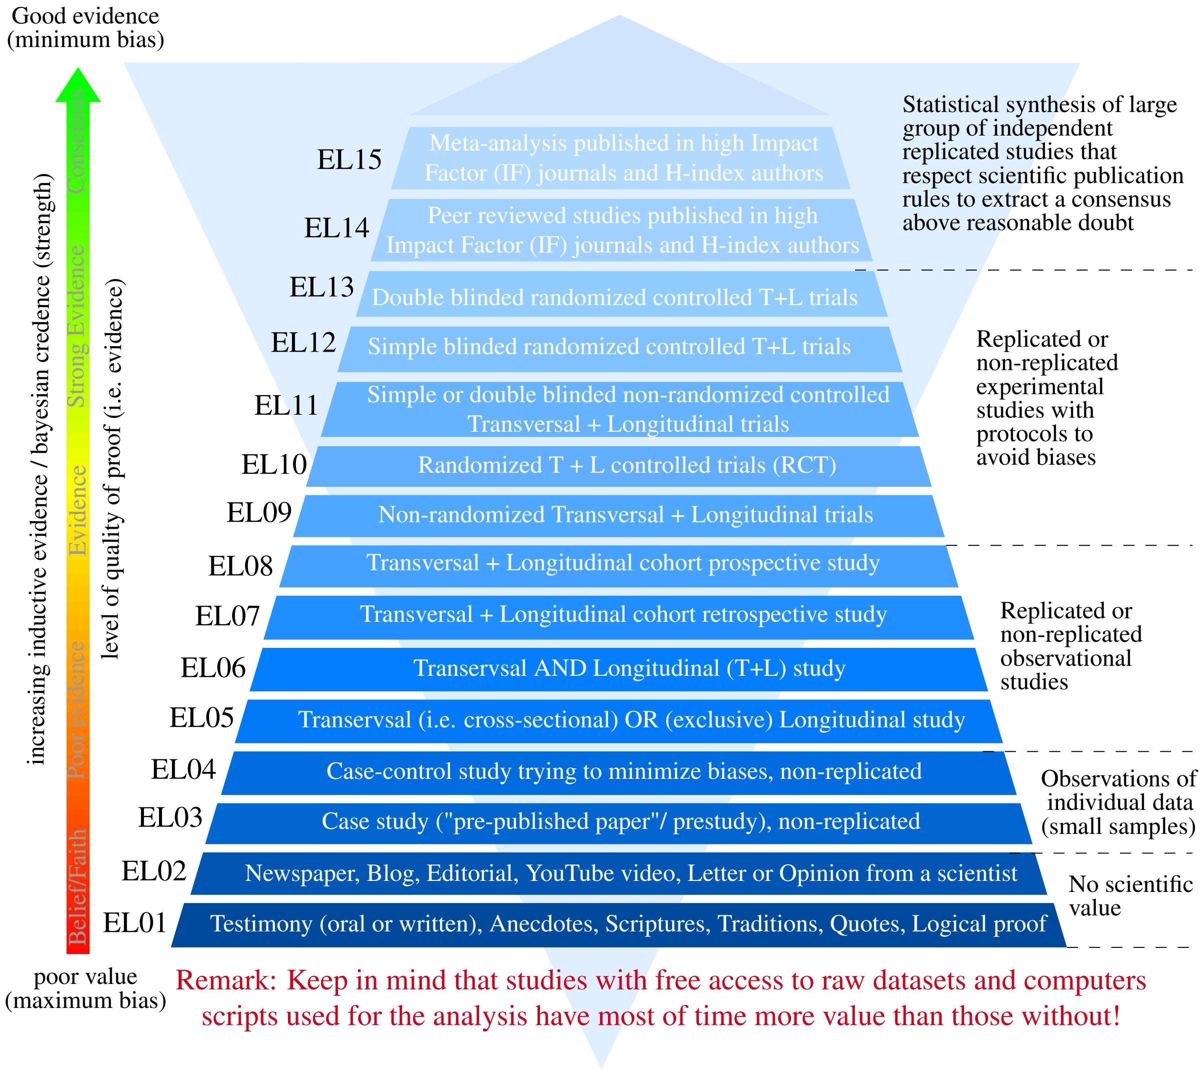
[17] The simplest trial design is a "single-arm trial". In this design, a sample of individuals with the targeted medical condition is given the experimental therapy and then followed over time to observe their response. In a "double-arm trial" half of the people will receive a "placebo" or "standard of care[18]" as reference (exposure group vs non-exposure group). In a "triple-arm trial" a third will receive a competitive treatment. In the general case we speak of "multi-arm trial".

[19] In the science of drugs, a "pure placebo" is a treatment without any active substance; an "impure placebo" is a pharmacologically active product but having no effect on the pathology treated, or whose efficacy has not been sufficiently demonstrated.

[20] If you doubt of the utility in every day life of the CERN, just keep in mind that it is in this fundamental research center that the world wide web has been invented, but also touch-screens, tracker balls, robust chips for nuclear power plants, bid data visualisation softwares, hybrid pixelated detectors, gas electron multiplier, superconductivity technologies for tokamaks and nuclear magnetic resonance scanner, etc.

A common approach is to base the analysis on only some of the data, excluding the part in which an anomaly is thought to be hiding. The excluded data is said to be in a "black box" or "hidden signal box[21]".

Take the search for the Higgs boson. Using data collected with the CERN's Large Hadron Collider (LHC) until the end of 12011 (holocene calendar), researchers saw hints of a bump as a potential sign of a new particle with a mass of about 125 gigaelectronvolts. So when they looked at new data, they deliberately quarantined the mass range around this bump and focused on the remaining data instead.



Good evidence
(minimum bias)
Consensus
Strong Evidence
Evidence
Poor evidence
Belief/Faith
increasing inductive evidence / bayesian credence (strength)

EL01
Testimony (oral or written), Anecdotes, Scriptures, Traditions, Quotes, Logical proof
Statistical synthesis of large group of independent replicated studies that respect scientific publication rules to extract a consensus above reasonable doubt
Replicated or non-replicated experimental studies with protocols to avoid biases
Replicated or non-replicated observational studies
Observations of individual data (small samples)
No scientific value
poor value
(maximum bias)

Remark: Keep in mind that studies with free access to raw datasets and computers scripts used for the analysis have most of time more value than those without!

Figure 4.6: **Scientific evidence hierarchy (assuming each level is made "at its best")**

The figure above[22] that applies to multiple fields of Science (physics, chemistry, biology, genetics, epidemiology, social science, economy, psychology, archaeology, astrophysics, astronomy, cosmology, epidemiology) illustrates in the lowest level of evidence EL01 the obvious fact that we should never trust the opinions and beliefs of scientists (even less "corporate scientists"...), physicians, doctors and engineers (these latter are not scientists by the way, see for example [500] and [190]!) - because science must not be driven by humans beliefs and opinions (!) - but only by the evidence provided by the **DATA** from reproducible independent experiments provided with their statistical analysis at a meta-analysis level inhigh Impact Factor (IF) peer reviewed papers with high H-index (HI) authors !

---

[21] Injecting false signals in scientific detectors is also a periodic common quality routine test in professional research to check the robustness of the scientific processes and the unbiased behavior of researchers.

[22] The huge majority of techniques and methods mentioned in each of the rows of the figure are proven and explained in the section Statistics starting from page 542 and in the section of Numerical methods starting from page 6316.

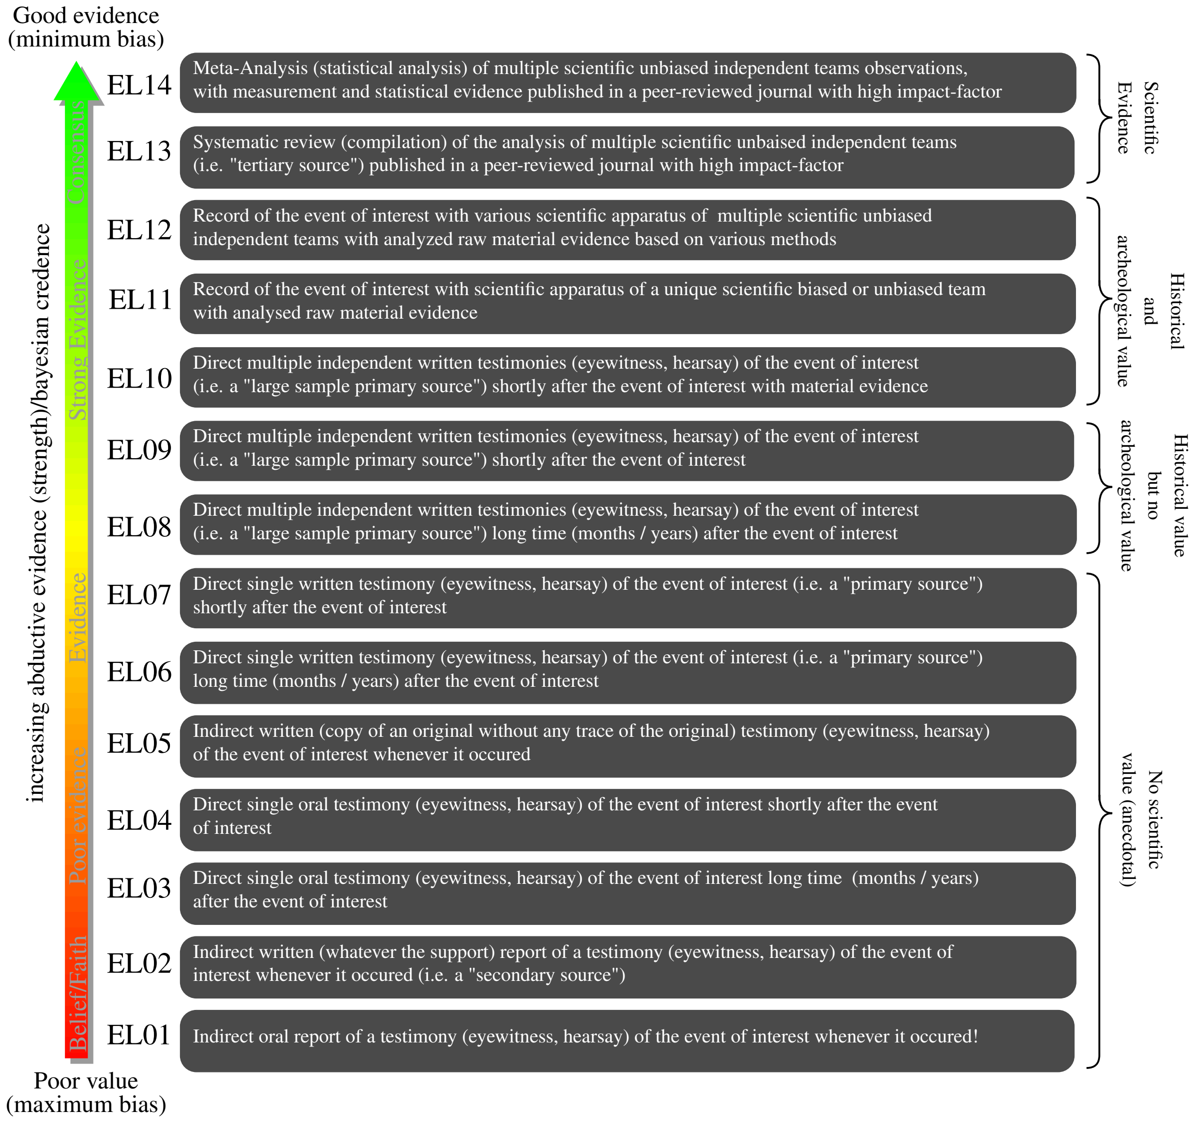
Caution! We can find on Internet plenty of professional looking websites administered by anonymous people (that try hard to hide who they are, in what country they live and what business they run...) compiling meta-analysis! However a website that is anonymous - having by definition a zero H-index - is obviously suspect especially when they cherry-pick only studies that goes in the direction of their political and religious agenda and don't provide the source code to reproduce the results. The same goes for some textbooks that want to pass themselves off as textbooks and published by editor with dubious catalogue and having no affiliation with a major university. In this early 121st century, the content of journal with an H-index below 500 and an Impact Factor below 10 must be taken with extreme precaution and not be considered as written by highly skilled professional scientists.

For example the above level of evidence doesn't applied to History as we cannot repeat or observe the past (at the opposite of astrophysics where the further we look, the further we go back into the life of the Universe we see!). In History the basic rules (undergraduate level) for example are to consider the three different type of sources below:

PRIMARY SOURCE	SECONDARY SOURCE	TERTIARY SOURCE
Definition: raw data; original source of information before it has been analyzed; written by the protagonist of the topic	**Definition:** sources that analyze, interpret or story tell primary data testimonials; they do not offer new evidence and don't constitute evidence; not original	**Definition:** Sources that compile data on a particular topic.
Characteristics: first-hand observation/account;protagonist wrote it;contemporary accounts of events; original dated document	**Characteristics:** interpretation of information; written after the event of interest; offer review or critique;	**Characteristics:** collections or lists of primary an secondary sources; reference works;finding tools for sources
Examples: interviews; speeches; diaries; birth certificates; coins; dated measurement original articles; originals written at the time; experiments account	**Examples:** biographies; journal articles; textbooks; commentaries; editorial; holy books; videos reproducing the events	**Examples:** encyclopedias; bibliographies; abstracts indexes; literature; reviews; library catalogs; databases; this textbook (Opera Magistris)

Table 4.2: **Reminder of the difference scale of Sources in Sciences**

But at a graduate and postgraduate level we have the following actual (nothing is fixed for ever) hierarchy of scientific evidence in the field of History (this hierarchy is rarely taught because they may hurt and offend many believers and even put in cognitive dissonance a significant proportion of professionals - teachers and professors - who have important anchor biases):



Good evidence
(minimum bias)
increasing abductive evidence (strength)/bayesian credence
Consensus
Strong Evidence
Evidence
Poor evidence
Belief/Faith
Poor value
(maximum bias)
Scientific Evidence
Historical and archeological value
Historical value but no archeological value
No scientific value (anecdotal)

EL14 Meta-Analysis (statistical analysis) of multiple scientific unbiased independent teams observations, with measurement and statistical evidence published in a peer-reviewed journal with high impact-factor

EL13 Systematic review (compilation) of the analysis of multiple scientific unbaised independent teams (i.e. "tertiary source") published in a peer-reviewed journal with high impact-factor

EL12 Record of the event of interest with various scientific apparatus of multiple scientific unbiased independent teams with analyzed raw material evidence based on various methods

EL11 Record of the event of interest with scientific apparatus of a unique scientific biased or unbiased team with analysed raw material evidence

EL10 Direct multiple independent written testimonies (eyewitness, hearsay) of the event of interest (i.e. a "large sample primary source") shortly after the event of interest with material evidence

EL09 Direct multiple independent written testimonies (eyewitness, hearsay) of the event of interest (i.e. a "large sample primary source") shortly after the event of interest

EL08 Direct multiple independent written testimonies (eyewitness, hearsay) of the event of interest (i.e. a "large sample primary source") long time (months / years) after the event of interest

EL07 Direct single written testimony (eyewitness, hearsay) of the event of interest (i.e. a "primary source") shortly after the event of interest

EL06 Direct single written testimony (eyewitness, hearsay) of the event of interest (i.e. a "primary source") long time (months / years) after the event of interest

EL05 Indirect written (copy of an original without any trace of the original) testimony (eyewitness, hearsay) of the event of interest whenever it occured

EL04 Direct single oral testimony (eyewitness, hearsay) of the event of interest shortly after the event of interest

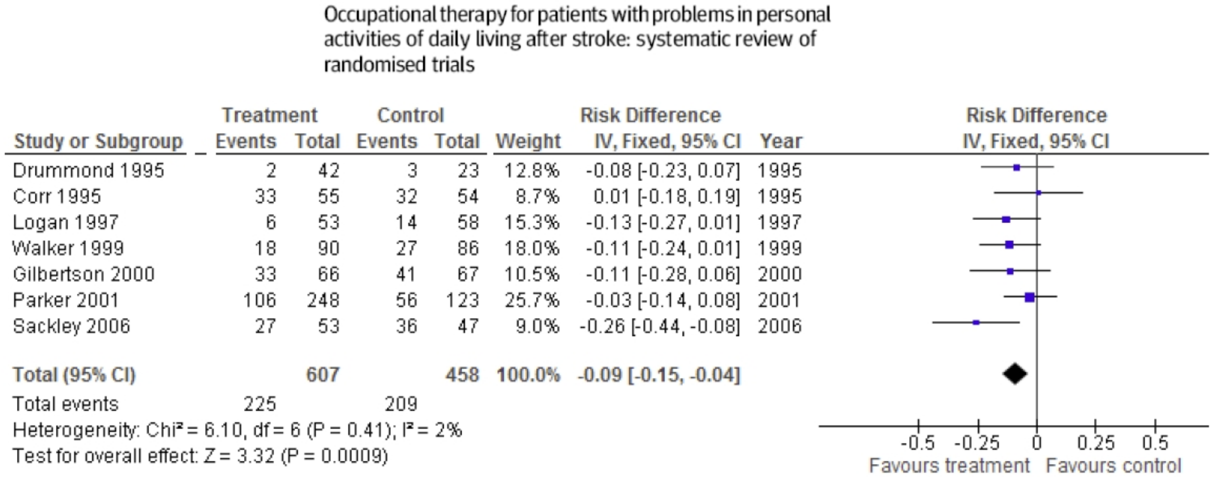
EL03 Direct single oral testimony (eyewitness, hearsay) of the event of interest long time (months / years) after the event of interest

EL02 Indirect written (whatever the support) report of a testimony (eyewitness, hearsay) of the event of interest whenever it occured (i.e. a "secondary source")

EL01 Indirect oral report of a testimony (eyewitness, hearsay) of the event of interest whenever it occured!

Figure 4.7: **Levels of Evidence in a social science like History**

As we can see from the both scales of evidence above, an important safety check to ensure that scientific claims are trustworthy is "replication"! If novel findings from scientific research can be reproduced, it means they are more likely to be valid. On the other hand, if the findings cannot be replicated they are likely to be invalid. Therefore, no single study (not even a randomized controlled trial) can be considered to be strong evidence – it is merely indicative. For this reason, we prefer meta-analyses. A meta-analysis is a summary of studies in which statistical analysis techniques are used to combine the results of individual studies to get a more accurate estimate of the effect. Thus, irrespective of the type of question, meta-analyses are often the most appropriate research designs. In other words, it is the body of evidence that is important – not single studies!



Occupational therapy for patients with problems in personal activities of daily living after stroke: systematic review of randomised trials

Study or Subgroup	Treatment Events	Treatment Total	Control Events	Control Total	Weight	Risk Difference IV, Fixed, 95% CI	Year
Drummond 1995	2	42	3	23	12.8%	-0.08 [-0.23, 0.07]	1995
Corr 1995	33	55	32	54	8.7%	0.01 [-0.18, 0.19]	1995
Logan 1997	6	53	14	58	15.3%	-0.13 [-0.27, 0.01]	1997
Walker 1999	18	90	27	86	18.0%	-0.11 [-0.24, 0.01]	1999
Gilbertson 2000	33	66	41	67	10.5%	-0.11 [-0.28, 0.06]	2000

Total events	225		209				

Heterogeneity: Chi^2 = 6.10, df = 6 (P = 0.41); I^2 = 2%

Test for overall effect: Z = 3.32 (P = 0.0009)

Figure 4.8: **Special example of a meta-analysis in the field of clinical trials with concepts that we will detail without exception in this entire textbook (source: [344])**

Remark

Testimonials or personal anecdotes have almost no values if the sample size is small and biased and if there is no direct way to measure the related event directly! This is why Historical Evidence based on only a few testimonial written in a unique thousands of year old book have no scientific value (even if there is a dozens of such books with concordant testimonials).

Those who quote Nietzche:

> *There are no facts, only interpretations!*
>
> Friedrich Nietzsche

quote 4.2:63.#14

also don't understand that they are at the level EL01 because is that claim itself a fact...????

The LHC (CERN) scientists used that data to make sure they were working with a sufficiently accurate model. Then they "opened the box" (unblinding) and applied that same model to the untouched region. The bump turned out to be the long-sought Higgs particle[23].

That worked well for the Higgs researchers. However, as scientists involved with the Large Underground Xenon (LUX) experiment reported at the workshop, the "black box" method of blind analysis can cause problems if the data you're expressly not looking at contains rare events crucial to figuring out your model in the first place.

LUX has recently completed one of the world's most sensitive searches for WIMPs - hypothetical particles of dark matter[24], an invisible form of matter that is five times more prevalent than regular matter. LUX scientists have done a lot of work to guard LUX against background particles-building the detector in a cleanroom, filling it with thoroughly purified liquid, surrounding it with shielding and installing it under a mile of rock. But a few stray particles make it through nonetheless, and the scientists need to look at all of their data to find and eliminate them.

---

[23] Blinding and unblinding of experimental data analysis should be mandatory in all field of Science to avoid methodological biases!

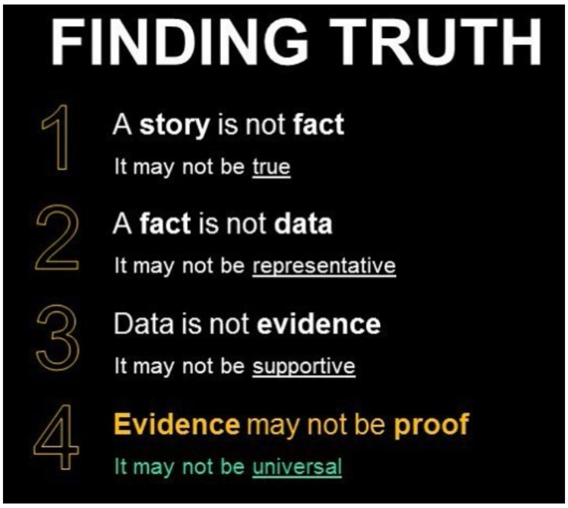
For that reason, LUX researchers chose a different blinding approach for their analyses. Instead of using a "black box", they use a process called "salting".

LUX scientists not involved in the most recent LUX analysis added fake events to the data - simulated signals that just look like real ones. Just like the patients in a blind drug trial, the LUX scientists didn't know whether they were analysing real or placebo data. Once they completed their analysis, the scientists that did the "salting" revealed which events were false.

A similar technique was used by LIGO scientists, who eventually made the first detection of extremely tiny ripples in space-time (for a naive and technical definition of "space-time" see the section of Special Relativity at page 5708) named "gravitational waves".

Not everyone in the scientific community is convinced that blinding is necessary. Blind analyses are more complicated to design than non-blind analyses and take more time to complete. Some scientists participating in blind analyses inevitably spend time looking at fake data, which can feel like a waste.

Typically some quite famous medical doctors and engineers (all are mathematics haters because they were very bad in this field during their studies and don't understand how to apply advanced statistics nor how to read the corresponding analytical results!) castigates the "totally randomized double-blind religion" and a medicine/engineering that has passed from the humanist hands of caregivers/inventors to the cold ones of statisticians and "methodologists". For sure (...) we know since long time that the rule of thumb, feelings and beliefs work much better than statistical method...



FINDING TRUTH

1 A **story** is not **fact**
It may not be true

2 A **fact** is not **data**
It may not be representative

3 Data is not **evidence**
It may not be supportive

4 **Evidence** may not be **proof**
It may not be universal

---

[24] Since June 12025 (holocene calendar) it is known thanks to FRB (Fast Radio Bursts) that approximately 76% of the Universe's baryonic matter lies in the IGM (InterGalactic Medium). About 15% resides in galaxy halos, and a small fraction is burrowed in stars or amid cold galactic galactic gas ([109]).

The reader must also keep in mind that we never claimed in this textbook that meta-analysis or RCT (randomized control trial) are the golden rule of evidence based science. We just claim that they are the tools that seems actually - at the time we write these lines - to give the best results. Obviously they are not perfect (as the humans conducting the experiments are also not perfect beings...) and sometimes they have failed but anyone criticizing meta-analysis and RCT should provide quantitative based evidence that there are other methods (mentioning which one) that performs statistically significantly better!

> ❞ *Most people don't really want the truth; they just want reassurance that what they already believe, is the truth.* ❞
>
> L. Aron Nelson

quote 4.2:65.#15

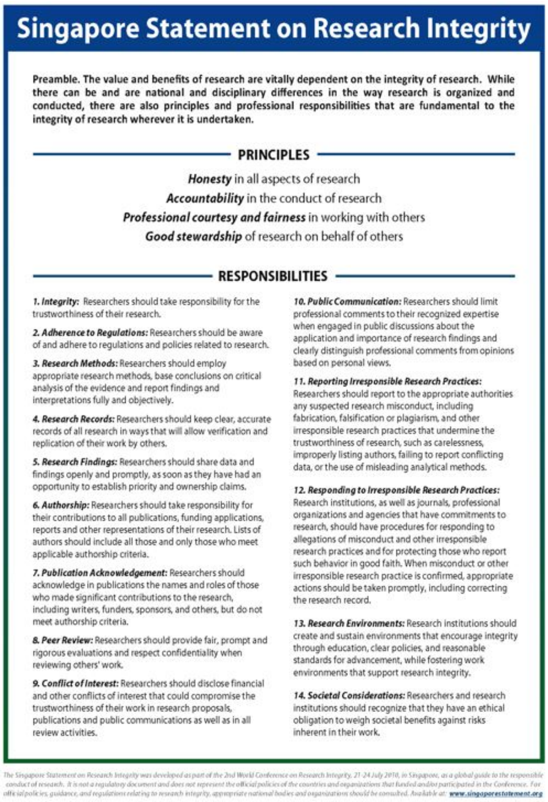
4.2.2 Research Integrity and Engineering/Scientific Ethics

Humans are trying at multiple levels to impose international standards of research integrity and engineering/scientific ethics.

Let us introduce three of the most famous one:

4.2.2.1 Singapore Statement on Research Integrity

The first one is the Singapore Statement on Research Integrity, drafted at the Second World Conference on Research Integrity, which took place in Singapore from July 21 to 24, 12010 (holocene calendar), that is an important step toward promoting ethical conduct among scientists around the world. The 340 conference attendees included scientists, journal editors, academic and industry leaders, and representatives from government funding agencies and publishers from over 51 countries. Nanyang Technological University, the National University of Singapore, the Singapore Management University, and the Agency for Science, Technology, and Research hosted the gathering, with support from Singapore's Ministry of Education and National Research Foundation. The Singapore statement was drafted by conference co-chairs, Nicholas Steneck (University of Michigan) and Tony Mayer (Nanyang Technological University), and the incoming chair for the next World Conference, Melissa Anderson (University of Minnesota). In contrast to the First World Conference, which took place in Lisbon, Portugal in 12007 (holocene calendar) and focused on misconduct issues, the goal of the Second World Conference was to make a concerted effort to promote global research integrity. The Singapore Statement is the fruit of this endeavour.



Singapore Statement on Research Integrity

Preamble. The value and benefits of research are vitally dependent on the integrity of research. While there can be and are national and disciplinary differences in the way research is organized and conducted, there are also principles and professional responsibilities that are fundamental to the integrity of research wherever it is undertaken.

PRINCIPLES

Honesty in all aspects of research
Accountability in the conduct of research
Professional courtesy and fairness in working with others
Good stewardship of research on behalf of others

RESPONSIBILITIES

1. Integrity: Researchers should take responsibility for the trustworthiness of their research.

2. Adherence to Regulations: Researchers should be aware of and adhere to regulations and policies related to research.

3. Research Methods: Researchers should employ appropriate research methods, base conclusions on critical analysis of the evidence and report findings and interpretations fully and objectively.

4. Research Records: Researchers should keep clear, accurate records of all research in ways that will allow verification and replication of their work by others.

5. Research Findings: Researchers should share data and findings openly and promptly, as soon as they have had an opportunity to establish priority and ownership claims.

6. Authorship: Researchers should take responsibility for their contributions to all publications, funding applications, reports and other representations of their research. Lists of authors should include all those and only those who meet applicable authorship criteria.

7. Publication Acknowledgement: Researchers should acknowledge in publications the names and roles of those who made significant contributions to the research, including writers, funders, sponsors, and others, but do not meet authorship criteria.

8. Peer Review: Researchers should provide fair, prompt and rigorous evaluations and respect confidentiality when reviewing others' work.

9. Conflict of Interest: Researchers should disclose financial and other conflicts of interest that could compromise the trustworthiness of their work in research proposals, publications and public communications as well as in all review activities.

10. Public Communication: Researchers should limit professional comments to their recognized expertise when engaged in public discussions about the application and importance of research findings and clearly distinguish professional comments from opinions based on personal views.

11. Reporting Irresponsible Research Practices: Researchers should report to the appropriate authorities any suspected research misconduct, including fabrication, falsification or plagiarism, and other irresponsible research practices that undermine the trustworthiness of research, such as carelessness, improperly listing authors, failing to report conflicting data, or the use of misleading analytical methods.

12. Responding to Irresponsible Research Practices: Research institutions, as well as journals, professional organizations and agencies that have commitments to research, should have procedures for responding to allegations of misconduct and other irresponsible research practices and for protecting those who report such behavior in good faith. When misconduct or other irresponsible research practice is confirmed, appropriate actions should be taken promptly, including correcting the research record.

13. Research Environments: Research institutions should create and sustain environments that encourage integrity through education, clear policies, and reasonable standards for advancement, while fostering work environments that support research integrity.

14. Societal Considerations: Researchers and research institutions should recognize that they have an ethical obligation to weigh societal benefits against risks inherent in their work.

The Singapore Statement on Research Integrity was developed as part of the 2nd World Conference on Research Integrity, 21-24 July 2010, in Singapore, as a global guide to the responsible conduct of research. It is not a regulatory document and does not represent the official policies of the countries and organizations that funded and/or participated in the Conference. For official policies, guidance, and regulations relating to research integrity, appropriate national bodies and organizations should be consulted. Available at: **www.singaporestatement.org**

4.2.2.2 European Code of Conduct for Research Integrity

The second one is the European Code of Conduct for Research Integrity that serves the European research community as a framework for self-regulation across all scientific and scholarly disciplines and for all research settings.

The European Code of Conduct for Research Integrity is a PDF of twenty A4 pages where only seven pages contains the code. The people interested to download it for free can just click on the following link:

The European
Code of Conduct for
Research Integrity
REVISED EDITION

4.2.2.3 Archimedean Oath

The last one is inspired by the Hippocratic Oath, a group of students of the École Polytechnique Fédérale de Lausanne in 11990 (holocene calendar) developed an oath of Archimedes expressing the responsibilities and duties of the engineer and technician. It was taken in various versions by other European engineering schools and could serve as basic inspiration oath for scientific researchers (however a few points are missing like as in medicine[25], to be struck off the order of scientists in the event of serious ethical error).

"Considering the life of Archimedes of Syracuse which illustrated as of Antiquity the ambivalent potential of the technique, considering the responsibility increasing for the engineers and scientists with regard to the men and nature, considering the importance of the ethical problems that the technique and its applications raise, today, I pledge following and will endeavour to tend towards the ideal which they represent:

01 I will practice my profession for the good of the people, in the respect of the Human Rights and of the Environment.

02 I will recognize, being as well as possible informed to me, the responsibility for my acts and will not discharge me to in no case on others.

03 I will endeavour to perfect my professional competences.

04 In the choice and the realization of my projects, I will remain attentive with their context and their consequences, in particular from the point of view technical, economic, social, ecological... I will pay a detailed attention to the projects being able to have fine soldiers.

05 I will contribute, in the measurement of my means, to promote equitable relationships between humans and to support the development of the countries lower-income group.

06 I will transmit, with rigour and honesty, with interlocutors chosen with understanding, any information important, if it represents an asset for the company or if its retention constitutes a danger to others. In the latter case, I will take care that information leads to concrete provisions.

07 I will not let myself dominate by the defense of my interests or those of my profession.

08 I will make an effort, in the measurement of my means, to lead my company to take into account the concerns of this Oath.

09 I will practice my profession in all intellectual honesty, with conscience and dignity.

10 I promise it solemnly, freely and on my honour."

---

[25] Let us recall that contrary to a well spread misconception that doctors and surgeons or any medical personnel are obviously not scientists (we leave it to the reader to do an extensive fact checking if that surprises him)!

Remark

Obviously, any engineer that has worked for Fortune 500 corporations knows that such an oath cannot be applied when the board committee and the managers are themselves not engineers and don't care about this oath (at the opposite of medicine where most of time all the hierarchy is made of doctor!). So the only possibility to apply this oath for engineers working is such structures is either to negotiate the respect of this oath during the hiring process (good luck...!) or to resign the contract... (what most engineers don't do and therefore they don't respect this oath...).

Sadly this oath should be completed with the "Münich Declaration of the Duties and Rights of Journalists" (year 11971 according to holocene calendar). That is, the essential duties of the scientist in gathering, reporting on and commenting on data consist in:

- Respecting the truth no matter what consequences it may bring about to him, and this is because the right of the public is to know the truth.
- Defending the freedom of information, of commentaries and of criticism.
- Publishing only such pieces of information the origin of which is known or – in the opposite case – accompanying them with due reservations; not suppressing essential information and not altering texts and documents.
- Not making use of disloyal methods to get information, photographs and documents.
- Feeling obliged to respect the private life of people.
- Correcting any published information which has proved to be inaccurate.
- Observing the professional secrecy and not divulging the source of information obtained confidentially.
- Abstaining from plagiarism, slander, defamation and unfounded accusations as well as from receiving any advantage owing to the publication or suppression of information.
- Never confusing the profession of journalist with that of advertiser or propagandist and not accepting any consideration, direct or not, from advertisers.
- Refusing any pressure and accepting editorial directives only from the leading persons in charge in the editorial office. Every journalist worthy of this name feels honoured to observe the above-mentioned principles; while recognising the law in force in each country, he does accept only the jurisdiction of his colleagues in professional matters, free from governmental or other interventions.

4.2.3 Scientific Publication Rules (SPR)

It is impossible to have a constructive debate or analysis if the basis material is unusable, unavailable or poorly defined. Sadly still in the 121st century (holocene calendar) it is quite easy to find Nobel prize peer-review scientific publications[26] (PRSP) that are scientifically unusable (furthermore there is a huge issue with profit oriented scientific journals that reject replication studies most of the time considering them as "boring", i.e. non-money profitable...). This is why we recall here the basic publication rules to follow to be accepted by a scientific peer review committee:

01 Use of LaTeX for the writing of the publication

02 All redaction files and raw data files must have ISO 9660 compliant names

03 The publication should have a GUID (a unique Digital Object Identifier - DOI - alike code)

04 Put the history of major and minor versions of the publication (eg: v3.6 r58) with dates (ISO 8601 date/time format) and respective status (eg: working paper, preprint, submitted, peer review, accepted, published, retracted) and related taxonomy field keywords at the beginning

05 Put the experiment (development) period date (ISO 8601 date/time format)

06 The typographical rules of the language in which the publication is written must be strictly respected

07 Write an abstract (problem statement, indication of methodology, hypotheses, protocol, main findings and conclusions)

08 Write an introduction (including literature review)

09 All measurement[27] units and mathematical notation must follow ISO 80000 standards

10 Use the "principle of precaution[28]" (use of conditional)

11 Use "reactive responses", that is to say the make the confrontations between hypotheses / data, hypotheses / facts, hypotheses / observations

12 Any borrowing or reproduction of a text from an external source (human or algorithmic) must be placed between quotation marks and referenced

---

[26] Some studies get published with no peer review at all, even studies from Nobel Prizes (...), are named "predatory publishers" flood the scientific literature with journals that are essentially fake, publishing any author who pays (see an exhaustive online list on `https://beallslist.net`).

[27] Measurement by the way must be recordable, reproducible and answer to one or multiple identified causalities.

[28] The of expressions like "...(we) believe...", "....(we have) faith...", "...(we) think..." in the conclusions are forbidden.

⑬ Use, when available, "leverage factors" to give substance and credit to the work by making reference to other corresponding publications on the same subject[29]

⑭ Material and Methods should be described in details and new vocabulary defined with precision. For theoretical papers, they should provide a link (URL) or reference where the full detailed proof can be found (if detailed proof is omitted in the original publication!). For experiments they should provide the detailed randomized double-blinded protocol[30]

⑮ Put high resolution print-screens of charts (including the mandatory measurement errors and confidence/prediction intervals visible on the charts with the source code to generate them for reproducibility!) or photos

⑯ Write the results and for experimental data always provide a statistical analysis to show if the effect seems significant or not (effect sizes[31], fluctuation intervals, confidence interval, averages, medians, standard deviations, standard errors, sample sizes, kurtosis, bayes factor, skewness, Risk Ratio (RR), Odds Ratio (OR), Absolute Risk Reduction (ARR) and if the p-value is communicated then the power of the test must also always be communicated and be at least around 80% to have a scientific value!)

⑰ Calculate the propagation of errors of measurement instruments

⑱ Write the precautional conclusion to avoid HARKing (Hypothesizing After Results Are Known)[32] and always remind that a single study is not conclusive but indicative AND also that the paper may be retracted if it contains methodological errors

⑲ Remove from the publication any explicit personal political position agenda (unscientific statements like "socialism is a mortal enemy"), social beliefs (unscientific statements like "there is only two genders anyway") or religious beliefs (unscientific statements like "peace be upon him" or "may ... have mercy" or "for the sake of..." or "prayers and thoughts")

⑳ Give access to the raw data in a non-proprietary format to the scientific community[33]

㉑ Give access to the scripts/codes (of Open Source softwares!) used for data analysis to the scientific community[34]

㉒ Give access to the LaTeX sources of the publication to the scientific community (the sources can therefore contain in the format of LaTeX comments many additional details on the experiment or on the mathematical proofs)

---

[29] This also the very important step of "personal review", that is to say a personal analysis of several tens / hundreds of scientific publications and that you have made one critical analysis that you use to build your own argument.

[30] Double-blinded to avoid typical scandals like, among many others well-known examples, the Jacques Benveniste affair...

[31] This indicator has for pros of not being dependent of the sample size.

[32] The conclusion for experimental results (reject null hypothesis or not) should be written before (!) the experiment is run and not changed afterwards to avoid human cognitive biases.

[33] There are international standards for this purpose like Study Data Tabulation (SDTM), Analysis Data Model (ADaM) and Standard for Exchange of Nonclinical Data (SEND)

[34] To avoid case like the famous (and shameful) Reinhart-Rogoff error...

㉓ Provide the exact version (with possibly minor version!) of the software used for the experimentation[35] (calculations, writing and others) as well as devices/machines[36]

㉔ Put the bibliography with the references (ISO 690 - Numerical) and give access to the corresponding BibTeX file freely (check at the same time that the articles cited really exist and have not been retracted)

㉕ Cite equivalent studies for meta-analysis[37]

㉖ For meta-analysis weighted confidence intervals, the Harbord's test, the Begg rank correlation test, the Egger test, the heterogeneity test (chi-square), the Macaskill test and the funnel plot must be provided

㉗ Acknowledgements and % financial support of each sponsor must be detailed (competing interests[38], funding sources)

㉘ Submit the paper to the peer review committee[39] (in single or double blind way[40])

㉙ List all actors (with position, grade from which university, e-mail[41] and religious beliefs) and peer reviewers (only name for that latter) of the publication

Any publication that doesn't respect at least one of this rule cannot be considered as a "scientific" (i.e. "serious") publication! Many of the points above also applies to video content (typically TEDx videos or YouTube videos - or any other platform - where the speaker in a comfortable monologue[42]... - doesn't cite the sources and meta-analysis when arguing or exposing its "personal experience", "opinions", or "expertise").

The list of constraints above leads us to the obvious conclusion that just because you're reading an article about science doesn't mean it's a scientific article!

---

[35] Ideally you should keep a virtual machine with the configuration, the software version and the libraries for subsequent reproducibility.

[36] The experiment must be sufficiently detailed to be identically reproducible (or it is also necessary to specify the factors which would make the experiment likely to be non-reproducible).

[37] If there are no equivalent studies, then no meta-analysis are possible, then the results and conclusions don't reach any scientific consensus for recall!

[38] Not only industrial and economic, but also religious like working for a non-secular university!

[39] Notice that if all scientists followed these rule, peer review committees, with their bias and mood influence, would not be necessary anymore as the validation of a scientific paper could be quite easily automated.

[40] "single blind" is that the peer reviews doesn't know the name of the authors, "double blind" is that neither the authors nor the reviewers know each others' identities.

[41] And eventually with gender type, country of origin, religious belief, and birth year for statistical purposes. Like: Albert Einstein (Researcher, PhD Physics ETHZ, a.einstein@ethz.ch, M, CHE, Deist, 11879)

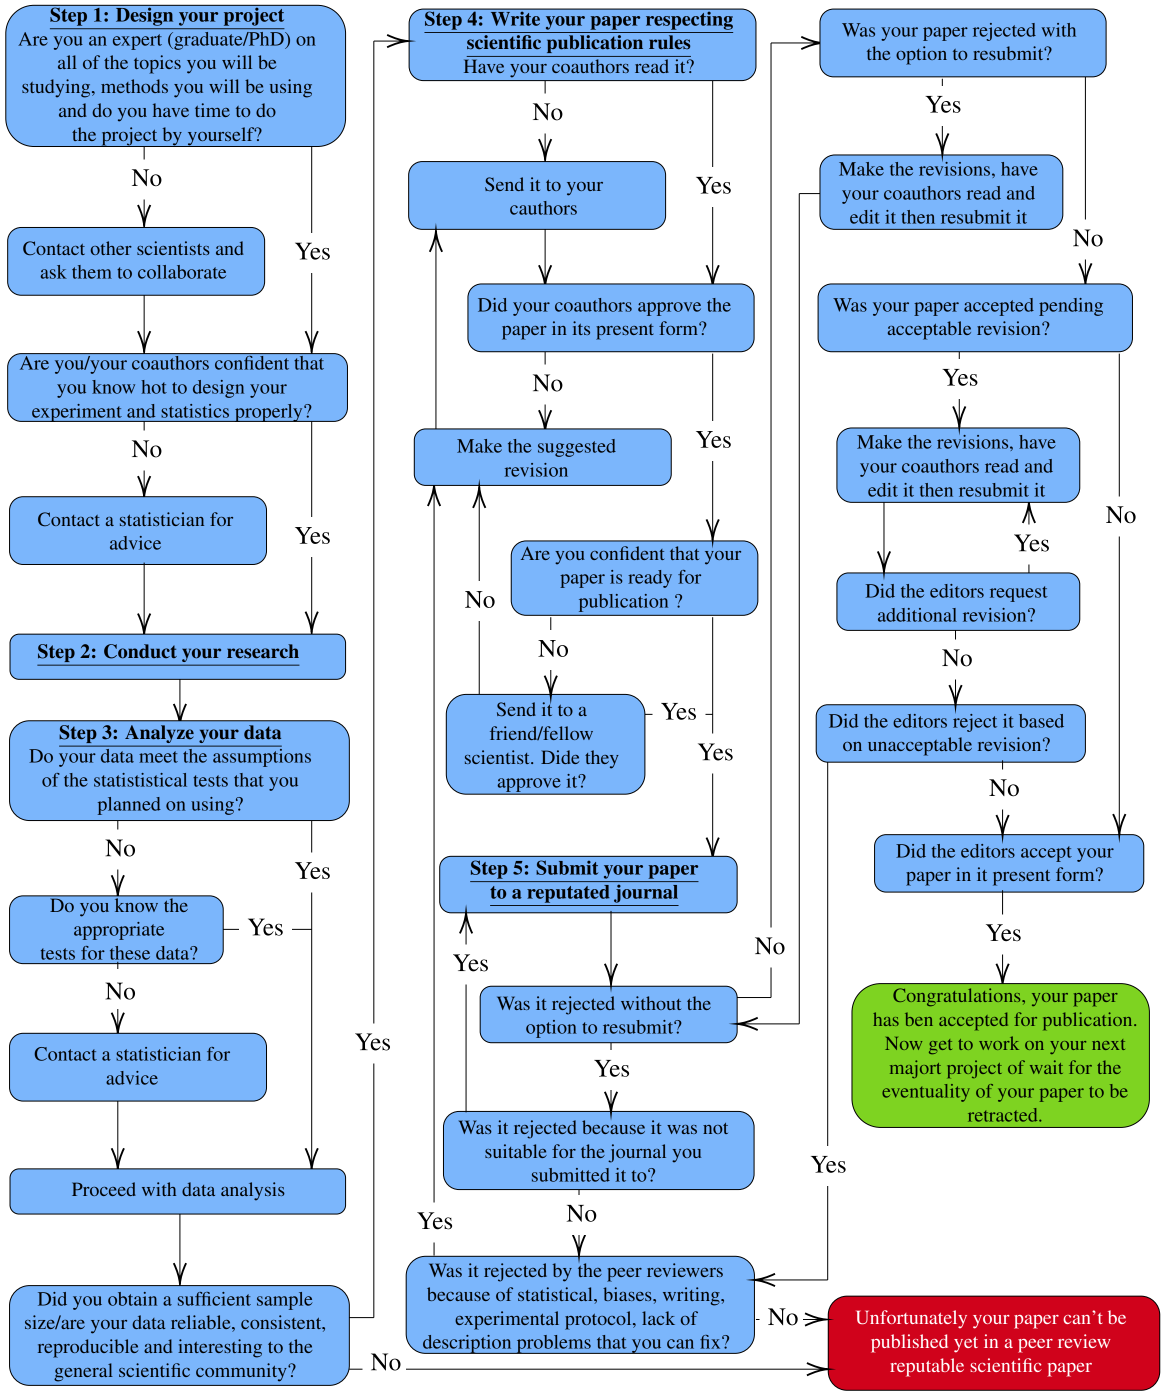
[42] People should not trust monologues - whether on radio, television or any social network - because there are no experts to counter the possible wrong arguments or ill-defined concepts that may lead a part of the audience to wrong speculative interpretations! In addition, humans under the stress of knowing that they are recorded are naturally prone to vocabulary errors and that's without counting the more than 200 cognitive biases in the brain which sometimes lead to the erroneous simplification of complex thoughts... !

Remark

There is an equivalent good list of 29 rules that has been which was proposed in 11996 (holocene calendar) dedicated to scientific systematic review reports! The last version is named "PRISMA 2020" where "PRISMA" stand for: *Preferred Reporting Items for Systematic Reviews and Meta-Analyses*. For more see: `http://prisma-statement.org`.

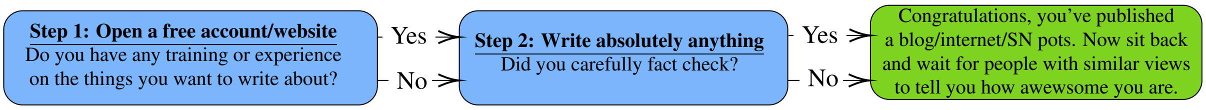
A photograph or video can be regarded as scientific evidence only if it meets the same methodological standards as empirical measurements: the phenomenon must be independently recorded by multiple qualified scientific teams, modelled in a way that yields predictive outcomes, subjected to rigorous statistical analysis, authenticated through forensic examination of the raw, unaltered files to exclude any computer-generated manipulation, and ultimately published in peer-reviewed journals in accordance with the scientific publication rules given above!

How To Publish Peer Reviewed Literature



Step 1: Design your project
Are you an expert (graduate/PhD) on all of the topics you will be studying, methods you will be using and do you have time to do the project by yourself?
No
Yes
Contact other scientists and ask them to collaborate
Are you/your coauthors confident that you know hot to design your experiment and statistics properly?
No
Yes
Contact a statistician for advice
Step 2: Conduct your research
Step 3: Analyze your data
Do your data meet the assumptions of the statistical tests that you planned on using?
No
Yes
Do you know the appropriate tests for these data?
Yes
No
Contact a statistician for advice
Proceed with data analysis
Did you obtain a sufficient sample size/are your data reliable, consistent, reproducible and interesting to the general scientific community?
Yes
No
Step 4: Write your paper respecting scientific publication rules
Have your coauthors read it?
No
Yes
Send it to your cauthors
Did your coauthors approve the paper in its present form?
No
Yes
Make the suggested revision
Are you confident that your paper is ready for publication ?
No
No
Yes
Send it to a friend/fellow scientist. Dide they approve it?
Yes
Yes
Step 5: Submit your paper to a reputated journal
Yes
Was it rejected without the option to resubmit?
No
Yes
Was it rejected because it was not suitable for the journal you submitted it to?
Yes
No
Was it rejected by the peer reviewers because of statistical, biases, writing, experimental protocol, lack of description problems that you can fix?
No
Unfortunately your paper can't be published yet in a peer review reputable scientific paper
Was your paper rejected with the option to resubmit?
Yes
Make the revisions, have your coauthors read and edit it then resubmit it
No
Was your paper accepted pending acceptable revision?
Yes
Make the revisions, have your coauthors read and edit it then resubmit it
Yes
No
Did the editors request additional revision?
No
Did the editors reject it based on unacceptable revision?
No
Yes
Did the editors accept your paper in it present form?
Yes
Congratulations, your paper has ben accepted for publication. Now get to work on your next majort project of wait for the eventuality of your paper to be retracted.

How To Publish A Blog/Internet/Social Network Post



Step 1: Open a free account/website
Do you have any training or experience on the things you want to write about?
Yes
No
Step 2: Write absolutely anything
Did you carefully fact check?
Yes
No
Congratulations, you've published a blog/internet/SN pots. Now sit back and wait for people with similar views to tell you how awesome you are.

Figure 4.9: **How to publish peer review literature (source: https://www.thelogicofscience.com)**

The fact of being published in a peer-reviewed journal, however, does not guarantee the quality of an article! This is indeed an interesting fact that deserves to be underlined again and studied. Is it surprising ? Obviously not! All "publishers" know that the "reviewers" who judge the quality of articles submitted to journals are themselves researchers, caught up in the spiral of their own work and teachings, which have neither the desire nor the material possibility of check step by step all the calculations of an article in theoretical physics or all the references of an article in human sciences. This is not their mission. The vast majority of clearly erroneous articles are rejected by the system (the authors of the failed hoaxes do not suck and no one will know how many were foiled). Some, however, pass through the filters. It is obviously regrettable but perfectly well known to each concerned community. That of the hard sciences is not spared and notorious charlatans have managed to publish in respected and recognized journals. The hard sciences have not naturally been disqualified! These articles have simply been ignored for the vast majority of them (so unfortunately not all and especially those that do not detail all mathematical developments!): Neither read nor cited.

Remark

Even if there is a consensus at a given time between scientists (in 12021 according to holocene calendar, there was an estimate of approximately 9 million scientists around the World according to UNESCO), a unique oriented study (which can be very important) can be used to influence the opinion of mainstream media, governments and people. This is why a study must always be repeated, peer-reviewed and meta-analysed by independent teams and laboratories.

The existing H-index and IF (Impact Factor) index already used in the scientific publications field could be completed by an "SPR index" (Scientific Publication Rules) that gives the percentage of the number of rules listed above respected in a scientific article to give the level of scientific rigour of its content.

Caution! Some people think that a "scientific consensus" refers to a large group of scientists who agree in majority that something is "true" (i.e. have enough evidence to be actually considered as the most accurate model) at a given time. In reality, a scientific consensus is a large body of scientific studies that all agree with and support each other ("consensus of data"). The agreement among the scientists themselves is simply a by-product of the consistent evidence.

A well known example of non-existing consensus are religions. Indeed, if someone argue that as the statistics don't lie the christian god must exist as it is the most followed religion in the world with 2 billion Christians and that 2 billion people can't be wrong, you can recall this same person that as there is 7 billion people in the World, the 5 other billion that not believe in the christian god cannot be wrong as... statistic don't lie... Same if you merge Muslims and Christians together, then only 55% of the people in the World believe in a unique god and 55% is statistically not enough to reach the scientific consensus that is at a threshold level of 95%...

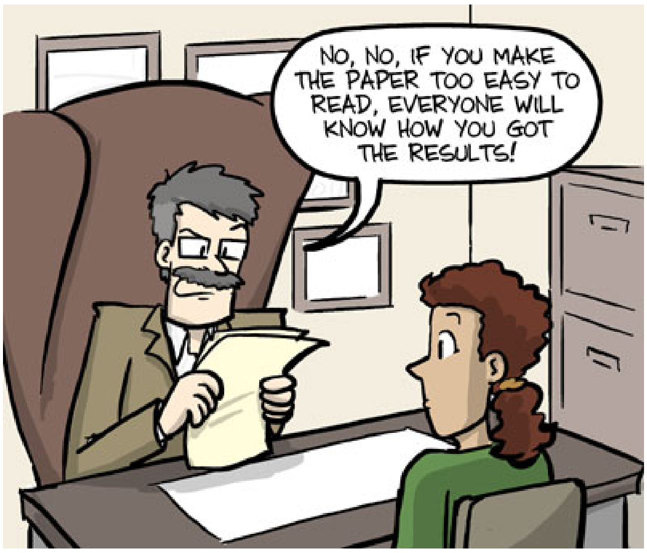
> ❞ *If a religion had even one true evidence beyond reasonable doubt, there would be no other religions!*

quote 4.2:75.#16

”

Remark

It is possible to logically provide evidence of the non-existence of any gods with certain attributes, by showing an inconsistency between those attributes and either the definition of the god or other established facts. For many examples of this, see [372].



NO, NO, IF YOU MAKE THE PAPER TOO EASY TO READ, EVERYONE WILL KNOW HOW YOU GOT THE RESULTS!

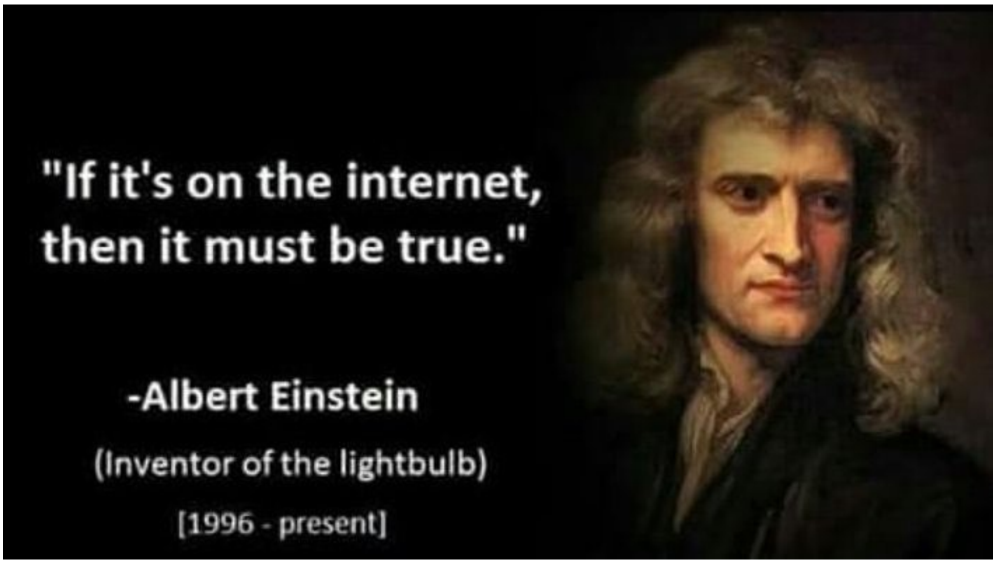
It is then easy to understand why Internet web pages and YouTube videos (or any other similar platform) are not a reliable scientific sources according to the above protocol as:

1. The peer-reviewers names are the huge majority of time not indicated
2. Contributor/Editors are anonymous and can therefore not be identified (typically an issue of Wikipedia)
3. The mathematical details are not provided (or even worst, there is not equations given at all!) so it is hard or even impossible to check by yourself if the reasoning is accurate
4. The experiment exact protocol is not given so it is impossible to know if the results are fake or real
5. No sources or cross-references are given
6. The content is not in a reliable format (a video or a web page are not perennial and protected[43] sources)
7. The new presented theoretical models predict indeed what the previous one do, but doesn't predict anything new and is therefore not falsifiable

---

[43] In the 121st century (holocene calendar) a PDF for example should be protected against edition and should also be electronically signed

8. The speaker on the video makes assumption that are not falsifiable (reference to god or to theories who mathematical details are not provided)
9. etc.



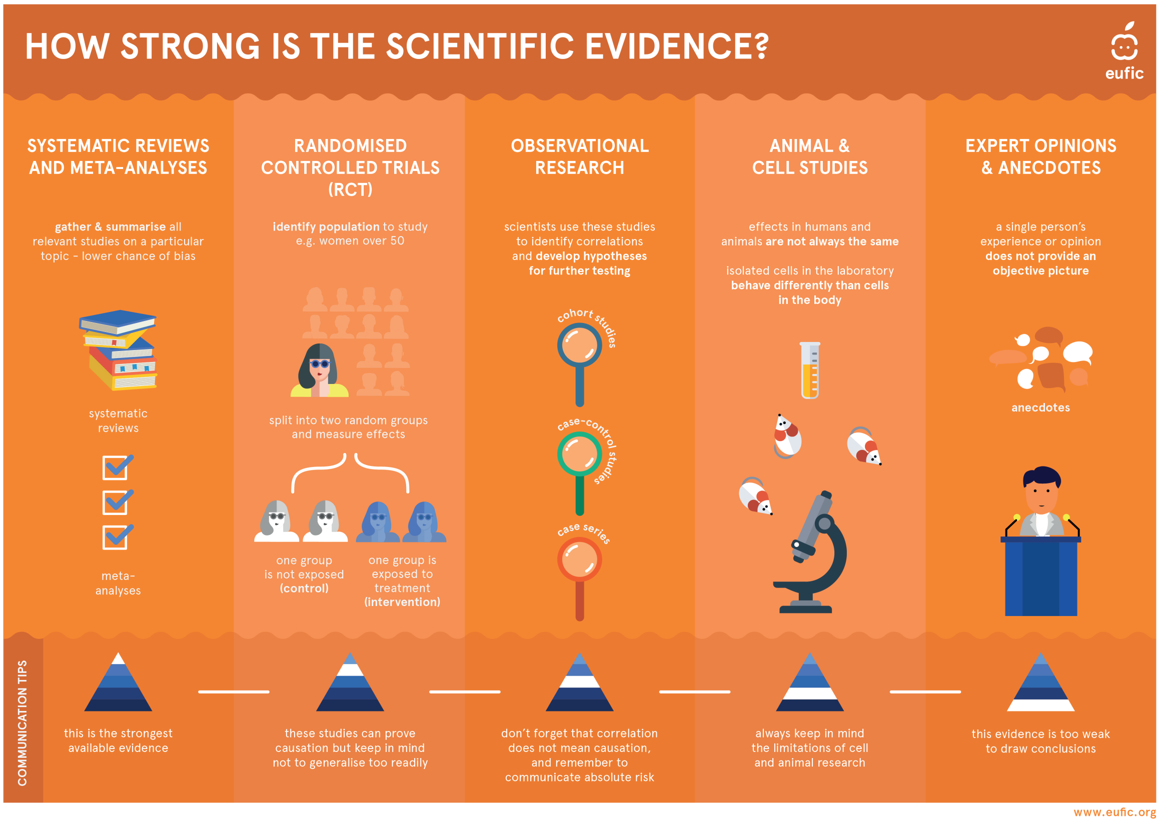
"If it's on the internet, then it must be true."
-Albert Einstein
(Inventor of the lightbulb)
[1996 - present]

The strength of scientific evidence produced by different types of studies (for instance systematic reviews, meta-analysis, randomised control trials, observational research, animal studies, cell studies and expert opinions) can vary.

Remark

The world is not systematically in line with our desires, our hopes, our prejudices, our philosophical aspirations, nor even with our apprehensions or our anxieties. It is not because it would be super cool to be able to move objects by the mere thought that this is necessarily possible. Likewise, it is not because he would be nice that a treatment for a rare disease exists that a therapeutic claim relating to this pathology is necessarily true. Our dreams, our hopes and our imagination are precious attributes of our humanity, which can put us in great danger if we forget that the associated intellectual productions are not due to us by reality. In the same vein, one thing is not necessarily true because it is conceivable that it is.

This infographic will help you understand the advantages and limitations of different types of scientific evidence:



HOW STRONG IS THE SCIENTIFIC EVIDENCE?
eufic
SYSTEMATIC REVIEWS AND META-ANALYSES
gather & summarise all relevant studies on a particular topic - lower chance of bias
systematic reviews
meta-analyses
RANDOMISED CONTROLLED TRIALS (RCT)
identify population to study e.g. women over 50
split into two random groups and measure effects
one group is not exposed (control)
one group is exposed to treatment (intervention)
OBSERVATIONAL RESEARCH
scientists use these studies to identify correlations and develop hypotheses for further testing
cohort studies
case-control studies
case series
ANIMAL & CELL STUDIES
effects in humans and animals are not always the same
isolated cells in the laboratory behave differently than cells in the body
EXPERT OPINIONS & ANECDOTES
a single person's experience or opinion does not provide an objective picture
anecdotes
COMMUNICATION TIPS
this is the strongest available evidence
these studies can prove causation but keep in mind not to generalise too readily
don't forget that correlation does not mean causation, and remember to communicate absolute risk
always keep in mind the limitations of cell and animal research
this evidence is too weak to draw conclusions
www.eufic.org

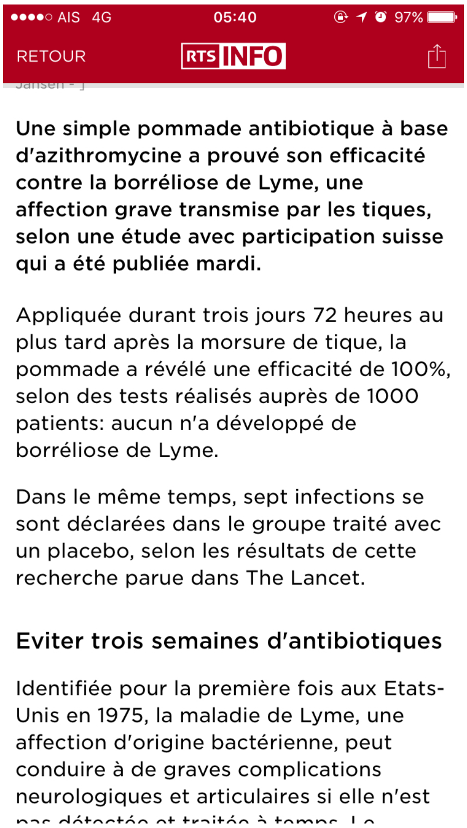
Figure 4.10: **Different types of scientific evidence (source: EUFIC)**

Anyway, we have to keep in mind that the popularity of a idea has no a priori relevance; the arguments must relate to the quality of the evidence, not its notoriety!

4.2.4 Scientific Mainstream Media communication

The reader of mainstream media or also (even worst!) social networks must never trust a scientific study if the reference and peer-reviewed paper is not given as link[44] (and if the paper does not respect the scientific publication rules that we have introduced earlier above page 70!). The study must also not be taken as "absolute truth" by the reader if there is a consensus of the scientific community on only... A UNIQUE ... study/publication[45] at a given time. The only way to be almost sure is to read the study itself and check if that latter respects the previous scientific publication rules, and this even more when you know that most mainstream medias are World champions in fall into the trap of cognitive biases (see section Game and Decision Theory page 7381) and data fallacies (see section Statistics page 1342).

A typical example of such an issue is a news that was taken by many international mainstream media on the Lyme borreliosis disease as following:



Une simple pommade antibiotique à base d'azithromycine a prouvé son efficacité contre la borréliose de Lyme, une affection grave transmise par les tiques, selon une étude avec participation suisse qui a été publiée mardi.

Appliquée durant trois jours 72 heures au plus tard après la morsure de tique, la pommade a révélé une efficacité de 100%, selon des tests réalisés auprès de 1000 patients: aucun n'a développé de borréliose de Lyme.

Dans le même temps, sept infections se sont déclarées dans le groupe traité avec un placebo, selon les résultats de cette recherche parue dans The Lancet.

Eviter trois semaines d'antibiotiques

Identifiée pour la première fois aux Etats-Unis en 1975, la maladie de Lyme, une affection d'origine bactérienne, peut conduire à de graves complications neurologiques et articulaires si elle n'est pas détectée et traitée à temps. Le

Figure 4.11: Swiss TV publication about Lyme borreliosis treatment the 12017-01-08 (source: RTS App)

In summary what the "scientific journalist" (humm humm... I think it must be a new intern in fact...), of one of the main National Swiss Television (so a TV that has enough money to investigate correctly any news... at least in theory... in a country that assess to be number one in almost everything...), has published is a very bad (catastrophic) interpretation of the original scientific publication. The above article report that: «*...a treatment applied during* 3

---

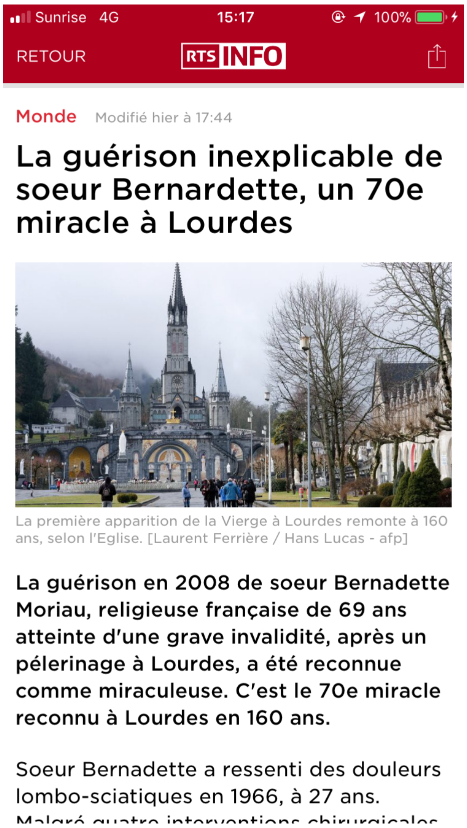
[44] And this is even more true for every information or brain-candy statistics as we will see later during our studies of percentages.

[45] Keep in mind that even a broken clock is right twice a day...

days not later than 72 hour after the bite of the tick has revealed and efficiency of 100%...». The most funny thing is that this article is provided by the Swiss Telegraph Agency (and afterwards relayed by Swiss TV) that says stupidly to be 100% accurate (this is the result of a country that gives a journalist accreditation after only 50 days of training...).

In reality (if medias did have read the publication until the end...) the study was stopped after 8 weeks and it has been shown that the treatment has no better effect than a placebo...

A second typical and recurrent mistake of the mainstream media is the confirmation bias (we will see the study of the biases later) of which here is a boring and ashamed example so much it is repeated (we may really think they do such errors on a given purpose ...):



Monde Modifié hier à 17:44

La guérison inexplicable de soeur Bernardette, un 70e miracle à Lourdes

La première apparition de la Vierge à Lourdes remonte à 160 ans, selon l'Eglise. [Laurent Ferrière / Hans Lucas - afp]

La guérison en 2008 de soeur Bernadette Moriau, religieuse française de 69 ans atteinte d'une grave invalidité, après un pélerinage à Lourdes, a été reconnue comme miraculeuse. C'est le 70e miracle reconnu à Lourdes en 160 ans.

Soeur Bernadette a ressenti des douleurs lombo-sciatiques en 1966, à 27 ans.
Malgré quatre interventions chirurgicales

Figure 4.12: **Swiss TV publication about a miracle in Lourdes the 12018-02-12 (source: App RTS/AFP)**

Of course, any person with a minimum of general knowledge can quite simply check through existing meta-analysis that "miracles[46]" are also occurring in hospitals and that in terms of "rates" of remission, Lourdes does not no better than mere chance in comparison to hospitals scattered all over the planet relative to this type of observation.

---

[46] A "miracle" is the term used by many people when they do not know how to explain an observed phenomenon. Eclipses were an example of a "miracle" not so long ago... If something can happen and does, it's hardly miraculous. So, a miracle must be something that can't happen. But, if a miracle does happen, then clearly, it can happen. And therefore it wasn't a miracle to begin with. So if life is full of miracles then you don't understand Nature and probabilities! Miracles have always been the snare of the ignorant and the refuge of the ambitious...

> *Everything is a sign or miracle when you don't understand Physics.*

quote 4.2:80.#17

It is therefore again shameful that one of the main Swiss national channel (a service that has enough money to properly investigate all information before relaying it ... at least in theory ... in a country that exclaims to be the number one in almost everything ...) has published biased information and this is even more shameful that this type of information comes from the AFP (Agence France Presse)...

We give also another similar problematic example in the section of Population Dynamics that occurred during the COVID-19 pandemic in France in 12021 (holocene calendar) at page 7345.

4.2.4.1 Social Networks

About social networks and scientific communication ... A priori we could see as well on Facebook, YouTube, Twitter, Instagram, TikTok during discussions or debates that:

- If we simplify the scientific discourse (thinking that I may be a good idea...) on some hot topics[47] we can be quickly enough be accused of distorting reality (this is the problem of indeed of simplification...!) or even to be condescending. And if you point out that you have simplified to make scientific illiterate people able to understand your argumentation, you will probably be accused of ad hominem attack. This is a situation afterwards where it is difficult or even impossible to restore confidence.
- If we do not simplify the scientific discourse (by using the vocabulary and quantitative methods of the field), or if we communicate the links to the scientific studies[48] or theories themselves, we are accused of hiding the truth or make statistics lie (or even to be condescending again!) thanks to an abscond vocabulary and the use of too technical terms and tools. The result is even worse when access the scientific papers are not in free access!
- If we are talking about a subject on which we have no expertise or diploma, or which is not our field of activity, we get "repacked" quickly (rightly!)
- On some groups and social networks accounts, some messages from a discussion may be deleted by administrators, this does not permit the possibility to support arguments or counter-arguments or just completely biases the discussion because some answers disappear or just simply never appear (some stakeholders or messages are typically hidden or deleted by the administrator).
- A small percentage of people are very well educated but may be biased because their are indoctrinated since childhood and even worst (because quite difficult to detect)... some are just trolls (with postgraduate curriculum) who enjoy to trigger people on social networks

---

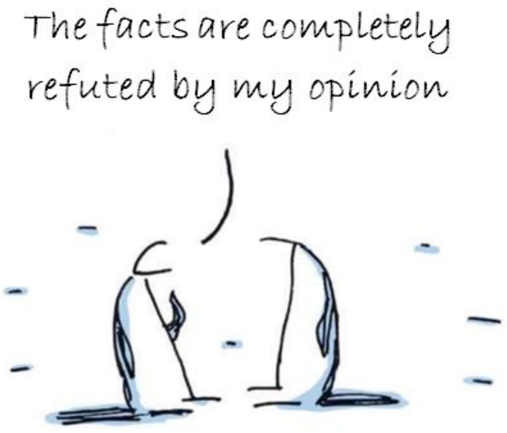
[47] Topics where typically people will tell you that: "the facts are denied by my opinion" ...

[48] Note that it seems to happen regularly that when links to the studies or meta-analysis are provided, there is almost always people to say that they are financed by lobbyists, or the links they were chosen in the sense of the defended arguments, or even that as not all the links towards all the studies of the world are provided then the given one are not representative...

just for the fun of reading the answers or... for the pleasure to analyse by curiosity the answers of people to their trolling.

- Statistically, 2.2% of open social networks users like Facebook, TikTok, Snapchat, Instagram (this excludes automatically social networks like ResearchGate obviously!) have an IQ below 70 points (and even some with higher IQ suffer of a sort of psychological paedomorphosis or of childhood indoctrination). In a country like France, that has in 12021 (holocene calendar) forty millions of daily active users, that makes $880,000$ users... and therefore quite a lot of uneducated, scientifically illiterate and non-rational people (taking into account that these kind of people are most of time jobless and therefore have much more to spend on social networks than PhD holder). That's why the mainstream social networks are frequented by plenty of WDKS representatives (World Dunning-Kruger Society).
- Finally keep in mind that all social networks do not support LaTeX, so it is impossible to have real scientific discussion (that is to say... using mathematical equations or chemical formulas).

The goal here is not to provide a scientific solution to these problems (it would be relevant, however, to conduct some studies on the subject ...!). However ... tricks that seem to work quite well are blocking comments on the content published by scientists or by the scientific community. To intervene in exchanges only if and only if you are invited to communicate as an external expert (and not to intervene on your own initiative).



The facts are completely refuted by my opinion

Finally, let us mention the spurious common argumentation techniques that are particularly flagrant on social networks (and in other media in general too ...) from those who are impervious to the scientific method and statistical analyses and simulations and that are voluntarily (or not?) inspired from the principles of war propaganda that the historian Anne Morelle has stated:

1. We do not want war (i.e. we do not want any "changes")
2. The opponents are the only one responsible for the war (it is he who forces the "unnatural changes")
3. The leader of the opponents has the face of the devil

4. This is a noble cause that we defend (eg a "public service") and not individual interests
5. The opponents knowingly provokes atrocities (eg murders, dismissals, deaths, ...) and if we commit mistakes it is involuntarily
6. The opponents uses unauthorized weapons (i.e. we do not understand the arguments of the opponents)
7. We suffer very little loss, the opponents losses are huge (the current system is good so we must not change it because it will be worse)
8. Artists and intellectuals support our cause
9. Our cause has a sacred character (eg truth seeker, public service, etc.)
10. Those who put in doubt our propaganda are traitors (i.e. they weaken the social cohesion, the national cohesion, try to make profit on the poorest, etc.)

This is typically "post-truth" circumstances as defined by the Oxford dictionary[49].

We can also add to this list the famous: «*I did my own research*». The guys searched two hundred hours on Twitter, YouTube and amateurs Blogs for scientific evidence by cherry picking and ignoring meta-analysis and this without the technical skills to understand scientific protocols and statistical (literally they pick up the first results on Google thinking that any text on the Internet or in a holy fictional book has a scientific value...).

NUCLEAR AND QUANTUM LAB
CHEMISTRY LAB
BIOMOLECULAR LAB
«DID MY OWN RESEARCH» LAB
Google

---

[49] Post-truth: relating to or denoting circumstances in which objective facts are less influential in shaping public opinion than appeals to emotion and personal belief.

No wonder, if the world is filled with empty and ridiculous opinions, there is nothing more capable of giving them course, than ignorance!

Furthermore, keep in mind the "Dunning-Kruger effect" that is a type of cognitive bias in which people believe that they are smarter and more capable than they really are. Essentially, low ability people do not possess the skills needed to recognize their own incompetence. The first rule of Dunning-Kruger club is you don't know you're in Dunning-Kruger club!

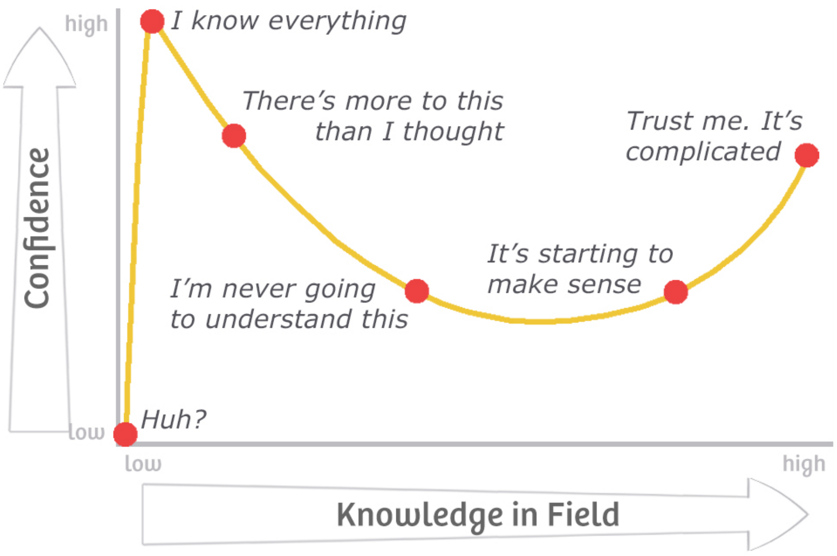


Figure 4.13: **Caricatural Dunning-Kruger effect curve (see the original paper of Dunning-Kruger for the original one)**

Remark

The most important mistake people make about the Dunning-Kruger effect, according to Dr. Dunning, has to do with who falls victim to it. «*The effect is about us, not them*» he wrote. «*The lesson of the effect was always about how we should be humble and cautious about ourselves.*» The Dunning-Kruger effect is not about dumb people. It's mostly about all of us when it comes to things we are not very competent at. Also some sociologist claim that these effect may not exist in reality and that it's a data artefact. As always anyway the conclusion is that educated people know that things are always more complicated than they seem to be...!

quote 4.2:84.#18

> *Ignorance more frequently begets confidence than does knowledge: it is those who know little, not those who know much, who so positively assert that this or that problem will never be solved by science.*
>
> Charles Darwin

4.2.4.2 Expert Opinions

We must also be careful with the method mainstream media choose to interview "experts".

Indeed, in science it doesn't make really sense to invite an expert to speak especially if the latter:

- Use arguments without providing detailed evidence (name of peer-reviewed meta-analysis)
- Don't make difference between "opinions" and "scientific based evidence"
- Speaks about subjects outside of his field of specialization
- Don't work anymore since many years in laboratories
- Use his awards and books to give himself a legitimate expert position
- Use his laboratory team work to promote himself
- Is alone doing a monologue[50] (typical of TEDx as already mentioned)
- Is interviewed by a scientifically illiterate journalist
- Is full of certitudes (the stupid are cocksure while the intelligent[51] are full of doubt)
- Has a mental illness (not to be confused with a physical disease)

There a lot of famous examples (like Nobel Prizes that have turned obsess by irrational subjects outside of their field of competence). However let us give two examples that we will meet later in this textbook again in different sections.

The first example is that Nosek's team that invited researchers to take part in a crowd-sourcing data analysis project. The setup was simple. Participants were all given the same data set and prompt: Do soccer referees give more red cards to dark-skinned players than light-skinned ones? They were then asked to submit their analytical approach for feedback from other teams before diving into the analysis.

Twenty-nine teams with a total of 61 analysts took part. The researchers used a wide variety of methods, ranging - for those of you interested in the methodological gore - from simple linear regression techniques to complex multilevel regressions and Bayesian approaches. They also made different decisions about which secondary variables to use in their analyses.

Despite analysing the same data, the researchers got a variety of results. Twenty teams concluded that soccer referees gave more red cards to dark-skinned players, and nine teams found no significant relationship between skin color and red cards.

---

[50] As already said people should not trust monologues - whether on radio, television or any social network - because there are no experts to counter the possible wrong arguments or ill-defined concepts that may lead a part of the audience to wrong speculative interpretations! In addition, humans under the stress of knowing that they are recorded are naturally prone to vocabulary errors and that's without counting the more than 200 cognitive biases in the brain which sometimes lead to the erroneous simplification of complex thoughts... !

[51] See the definition of "intelligence" at page 7385.

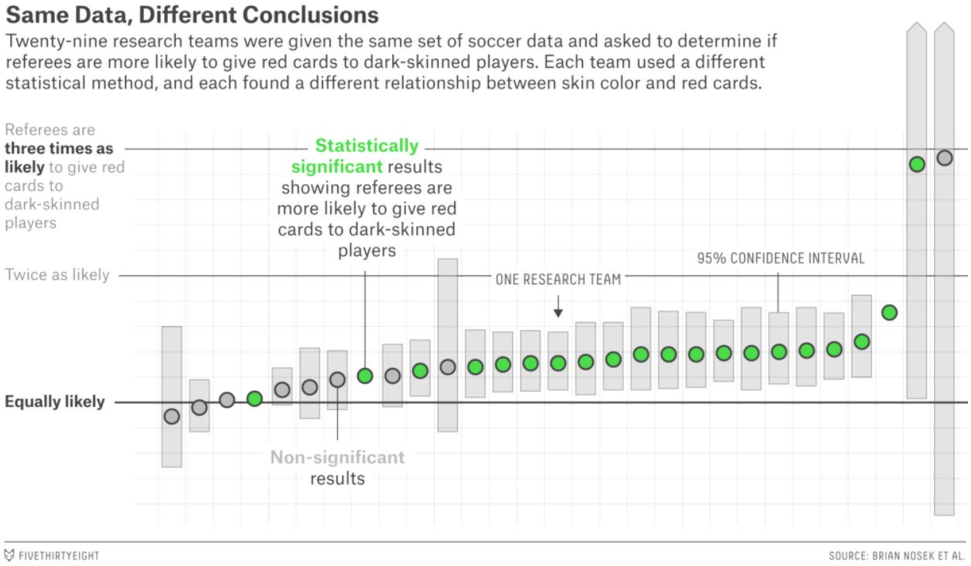

Figure 4.14: **Same data, different conclusions (purpose of meta-analysis)**

The variability in results wasn't due to fraud or sloppy work. These were highly competent analysts who were motivated to find the truth, said Eric Luis Uhlmann, a psychologist at the Insead Business School in Singapore and one of the project leaders. Even the most skilled researchers must make sometimes subjective choices that have a huge impact on the result they find. That's why again it is quite a non-sense to give only one expert to speak in mainstream media in a monologue[52]...

The second recent example (obviously it's special case that must not be generalized!) was the spread of the COVID-19 in the first trimester of year 12020 (holocene calendar) in the USA. It has been asked to a few US experts what is their prognosis for the number of positive COVID-19 cases in March 29 in USA. This was summarised in the following figure:

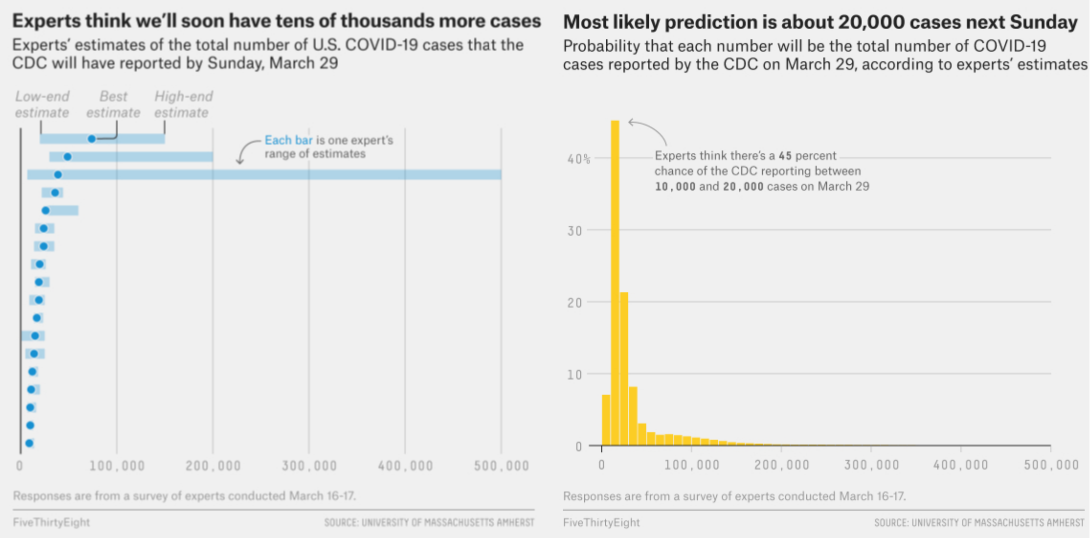

Figure 4.15: **Experts opinions/estimation issue**

---

[52] As already said people should not trust monologues - whether on radio, television or any social network - because there are no experts to counter the possible wrong arguments or ill-defined concepts that may lead a part of the audience to wrong speculative interpretations! In addition, humans under the stress of knowing that they are recorded are naturally prone to vocabulary errors and that's without counting the more than 200 cognitive biases in the brain which sometimes lead to the erroneous simplification of complex thoughts... !

For information, the number of positive cases known in March 29 in USA was in fact a bit above $100,000$. This is again a good example why a unique expert opinion or estimation - whatever the field - may not be always very reliable.

Obviously the reader must keep in mind that the variability exists in the above two examples because the scientists were not authorized to use the "Delphi method". Basically, the Delphi method is a process used to arrive at a group opinion or decision by surveying a panel of experts. Experts respond to several rounds of questionnaires, and the responses are aggregated and shared with the group after each round using statistical techniques (we will come back on that technique in the section Game and Decision Theory page 7392).

Statisticians do not in general exactly agree on how to analyse anything but the simplest of problems. The fact that statistical inference uses mathematics does not imply there is only one reasonable or useful way to conduct an analysis. Engineering uses math as well, but there are many ways to build a bridge. So trying multiple analyses given to multiple independent teams of researchers may be considered scientifically prudent to test the robustness of findings.

4.3. Vocabulary

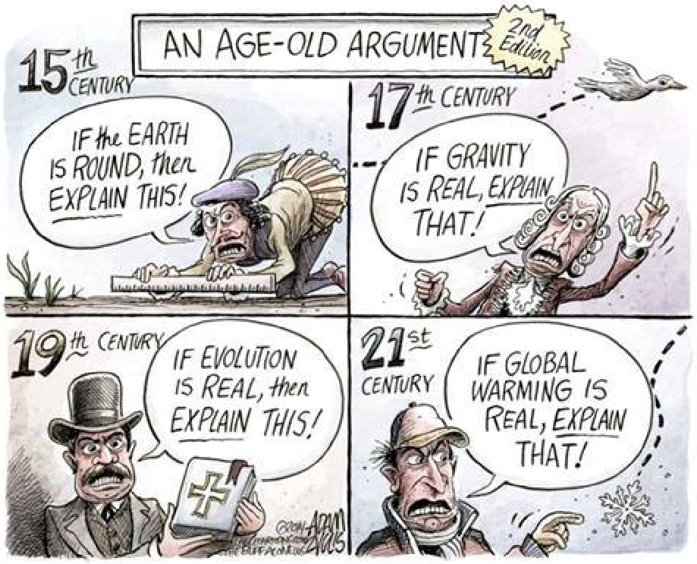
PHYSICS AND MATHEMATICS, like any field of specialization, has its own vocabulary. So that the reader is not lost in the understanding of certain texts he can read in this PDF, we have chosen to present here a few fundamentals words, abbreviations and definitions to know.

Thus, the mathematician like to finish his proofs (when he thinks they are correct) by the abbreviation "Q.E.D." which means "Quod Erat Demonstrandum" (this is Latin).

And during definitions (they are many in math and physics ...) scientist often use the following terminology:

- ... it is sufficient that ...
- ... if and only if ...
- ... necessary and sufficient ...
- ... means ...
- ... prove it ...

These five are not equivalent (identical in the strict sense). Because "it is sufficient that" correspond to a sufficient condition, but not to a necessary condition. Also it must be notice that these five are placed in the context of data analysis, data accuracy, reproduction and peer review and not on any personal or common belief or also emotional aspect of a group of people (even if this group of people is more than a few billion individuals...)!



AN AGE-OLD ARGUMENT
2nd Edition
15th CENTURY
IF the EARTH IS ROUND, then EXPLAIN THIS!
17th CENTURY
IF GRAVITY IS REAL, EXPLAIN THAT!
19th CENTURY
IF EVOLUTION IS REAL, then EXPLAIN THIS!
21st CENTURY
IF GLOBAL WARMING IS REAL, EXPLAIN THAT!

4.3.1 On Sciences

It is important that we define rigorously the different types of sciences to which humans often refers. Indeed, it seems that in the 121st century (holocene calendar) a misnomer is established and that it became impossible for people to distinguish the "intrinsic quality" between a "science" and another one.

Remark

Etymologically, the word "science" comes from the Latin "Scienta" (knowledge) whose root is the verb "scire" which means "to know".

This abuse of language is probably the fact that pure and accurate sciences lose their illusions of universality and objectivity, in the sense that they are self-correcting. This has for effect that some sciences are relegated to the background and try to borrow these methods, principles and origins to generate confusion. We must therefore be very careful about the claims of scientificity in the human sciences, and this is also (or especially) true for the dominant trends in economics, sociology and psychology. Quite simply, the issues addressed by the human sciences are extremely complex, poorly reproducible, and empirical arguments supporting their hypotheses are often quite low.

By itself, however, science does not produce absolute truth as we have already explained it numerous times. By principle, a scientific theory is valid as long as it can predict measurable and reproducible results that can be analysed statistically[53]. But the problems of interpretation of these results are part of natural philosophy.

No scientific theory is proven or provable (i.e. an absolute truth)! It is simply not falsified as long as a set of experiments have not provided contradictory evidence!!

Definitions (#4.3.4):

D1. A "scientific theory" is the best well-substantiated explanation/hypothesis of some aspect of the natural world that is based on a body of empirical[54], repeatable, measurable, controllable, verifiable, calculable and falsifiable evidence (generally condensed into a meta-analysis or systematic review analysis) and that has been tested and confirmed by inferential or abductive statistics at a significant threshold through multiples independent observations and experimentations. Unlike the everyday use of the word "theory", which might imply a guess or speculation, a scientific theory is grounded in empirical evidence and is widely accepted within the scientific community until proven otherwise.

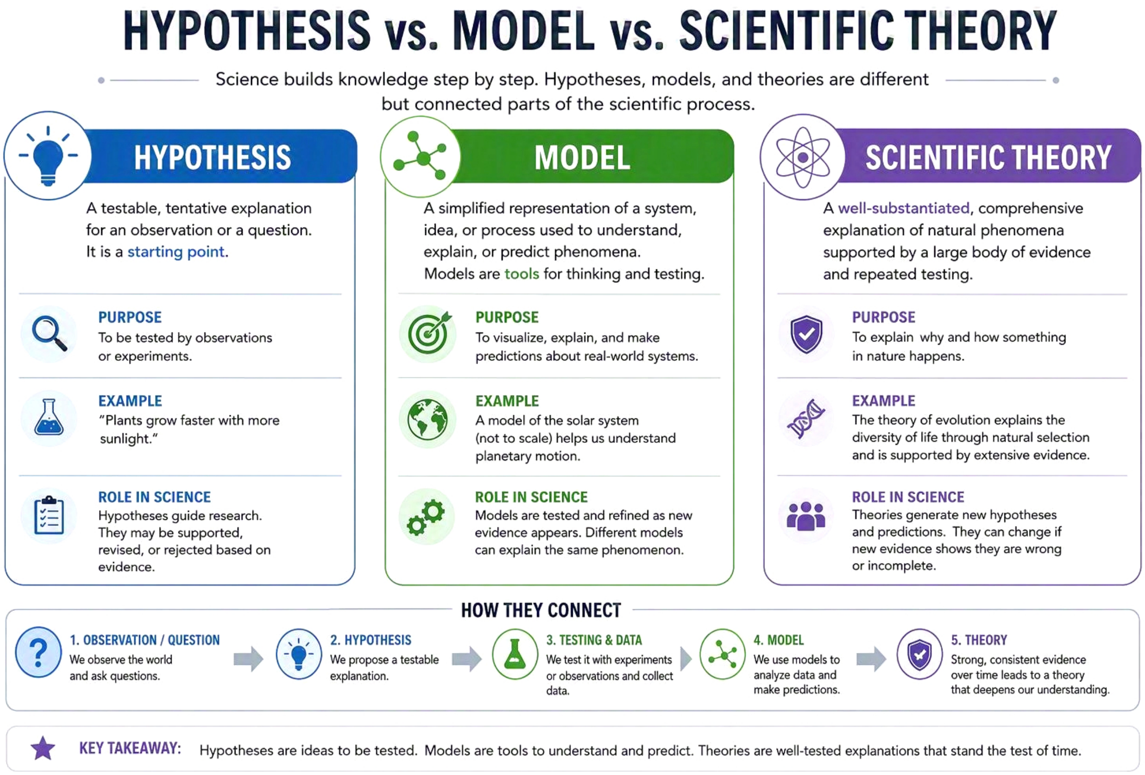
D2. A "scientific proof" is an exhaustive set of testable, measurable, and reproducible independent experiments that converge statistically, based on NHST (Null Hypothesis Statistical Testing) or BHST (Bayesian Statistical Testing(, on the same conclusion beyond reasonable doubt.

---

[53] So what we can read in all the various religious books existing around the world are not "scientific theories" but instead "speculative theories"!

[54] "Empirism" is academically defined by the state of a science when the facts based on the observation of the reality by accurate instruments and methods are not yet linked by any general theoretical model.

D3. A "scientific law", or commonly named "law", is a predictive formula obtained through experiment that hasn't any theoretical explanation yet (like Newton's law that was only later explained by the theoretical framework of General Relativity). Such laws work in the observable universe and are intelligible because they are human construction to approximate the reality.



HYPOTHESIS vs. MODEL vs. SCIENTIFIC THEORY

Science builds knowledge step by step. Hypotheses, models, and theories are different but connected parts of the scientific process.

HYPOTHESIS

A testable, tentative explanation for an observation or a question. It is a starting point.

PURPOSE
To be tested by observations or experiments.

EXAMPLE
"Plants grow faster with more sunlight."

ROLE IN SCIENCE
Hypotheses guide research. They may be supported, revised, or rejected based on evidence.

MODEL

A simplified representation of a system, idea, or process used to understand, explain, or predict phenomena. Models are tools for thinking and testing.

PURPOSE
To visualize, explain, and make predictions about real-world systems.

EXAMPLE
A model of the solar system (not to scale) helps us understand planetary motion.

ROLE IN SCIENCE
Models are tested and refined as new evidence appears. Different models can explain the same phenomenon.

SCIENTIFIC THEORY

A well-substantiated, comprehensive explanation of natural phenomena supported by a large body of evidence and repeated testing.

PURPOSE
To explain why and how something in nature happens.

EXAMPLE
The theory of evolution explains the diversity of life through natural selection and is supported by extensive evidence.

ROLE IN SCIENCE
Theories generate new hypotheses and predictions. They can change if new evidence shows they are wrong or incomplete.

HOW THEY CONNECT

1. OBSERVATION / QUESTION We observe the world and ask questions. →
2. HYPOTHESIS We propose a testable explanation. →
3. TESTING & DATA We test it with experiments or observations and collect data. →
4. MODEL We use models to analyze data and make predictions. →
5. THEORY Strong, consistent evidence over time leads to a theory that deepens our understanding.

★ **KEY TAKEAWAY:** Hypotheses are ideas to be tested. Models are tools to understand and predict. Theories are well-tested explanations that stand the test of time.

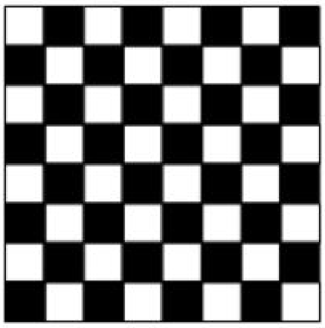
However, the scientific method is reliable enough so that Justice is not legitimate to take position on any scientific knowledge. And also the reader should keep in mind that actually, and as far as we know, it is impossible for the scientific method to prove that anything is empirically true. At best it can improve the likelihood of something to be true. The scientific method builds knowledge on experimental evidence, and provable mathematics models, not axioms. But experimental evidence verifies or falsifies theories, it does not prove them!!!!!!!!

Remark

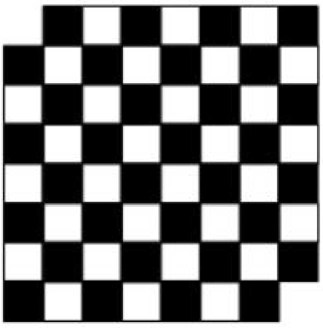
Hence keep in mind that a testimonial, or a simple sentence in a book or in a seminar even if said by a scientist has NO SCIENTIFIC VALUE, or no value for drawing conclusions, if it is not accompanied by data (typically proper, replicable, controlled scientific trials) and a mathematical detailed model! However, testimonials remains only useful by building speculative hypotheses and designing experiments and studies. If a speculative hypothesis is not accompanied by a methodology to test it experimentally, then it's still NOT science, but just free bullshit speculation! In a more elegant way we may say that it is: *pseudoscientific rhetoric aimed at a mathematically unsophisticated audience*!

If you don't get it (or you know people that don't get it), here is an illustrated example that may help to differentiate a "proof" and an "evidence":

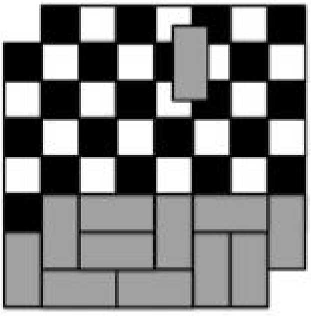
Let's imagine a chess board (a square board with black and white boxes in staggered rows) of 8 boxes per side. The board contains 64 boxes.



If we remove the two diagonally opposed boxes (two white boxes, in our case), there are 62 boxes remaining.



We propose to find a way to cover up all the remaining boxes with dominoes exactly the size of two chess boxes. All the chess boxes must be covered, and no domino must exceed the chess board.



The question is very simple: « is there at least one solution in which all the remaining chess boxes are covered, and no domino exceeds the chess board? »

- **Scientific Method:**

  An exact science is a science for which all theories are based on experiments. The scientific method consists thus to try all the possible ways to lay out the dominoes in order to cover up the chess board. After a certain number of tries, one might conclude that « It's impossible! I tried everything. » Scientifically speaking, the evidence is made that the problem has no solution.

But you will keep a doubt, deep inside you. Because maybe if you systematically eliminate all layouts, you'll finally end up on a layout that works. This would then break down the evidence of impossibility.

- **Mathematical method:**

  Each domino covers two chess boxes. A white one and a black one. On 62 remaining boxes, there are 32 black ones and 30 white ones.

  When 30 dominoes will be placed on the board, all the white boxes will be covered and there will be 2 black boxes not yet covered.

  Those two black boxes can not touch each other by a side. The best would be touching each other by a corner. A domino will thus be unable to cover both remaining boxes.

  The mathematical proof can not be argued and will never be contradicted.

Given the diversity of phenomena to be studied, over the centuries there has been a growing number of disciplines such as chemistry, biology, thermodynamics, etc. All these disciplines that are a priori heterogeneous have common foundation physics, for language mathematics, as grammar the statistics and for elementary principle the scientific method.

> ❞ *The sciences do not try to explain, they hardly even try to interpret, they mainly makes models. By a model is meant a mathematical construct which, with the addition of certain verbal interpretations, describes observed phenomena. The justification of such a mathematical construct is solely and precisely that it is expected to work-that is, correctly to describe phenomena from a reasonable wide area.* ❞
>
> J. von Neuman

quote 4.3:92.#19

Thus, a small memory refresh seems useful:

Definitions (#4.3.5):

D1. We define as "pure science" any set of knowledge based on rigorous reasoning (deductive logic) valid whatever the (arbitrary) elementary factor selected (when we say then "independent of sensible reality") and restricted to the minimum necessary. Only mathematics (often named the "queen of sciences") can be classified in this category.

D2. We define as "exact science" or "hard science" or "empirical science" or "evidence based science", any set of knowledge - appealing to no supernatural cause - based on the advanced statistical study of protocolized observations in the real world, observations that have been transcribed in symbolic form and that can be massively reproduced and refuted (theoretical physics for example... sometimes...). Primarily, the purpose of this kind of science is not to explain the "why" but the "how" and is based on deductive and abductive logic.

And never forget... Science (especially physics) doesn't have to "make sense" it just has to make all the right, testable predictions (instrumentalism)! According to the philosopher Karl Popper, a theory is scientifically acceptable if, as presented, it can be "falsifiable" (synonyms are "refutable" or "testable"), i.e. subjected to experimental tests[55] (or if it is possible to conceive of an observation or an argument which negates the statement in question). The "scientific knowledge" is then by definition the set of theories that have resisted to falsification (no amount of experimentation can ever prove you are right, but a single experiment can prove you are wrong!). Science is by nature subject to continuous questioning.

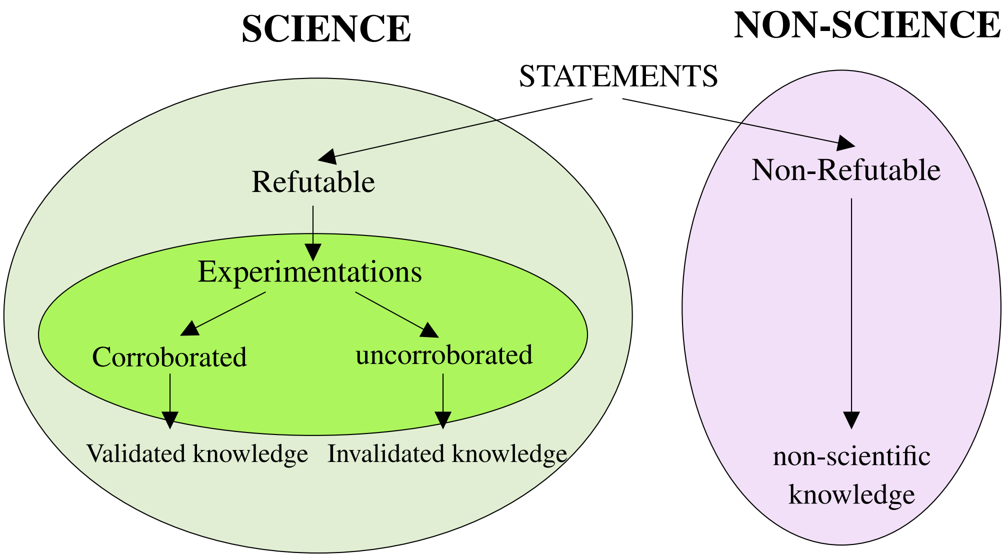
---

[55] That's why philosophy and naive human logic themselves can't "prove" anything. Because they strongly depend and vary from one socio-cultural context where people are born to another one (people from New-York have a quite different logic and philosophy from the Sentinelese tribe...). Without falsification science would be an anarchy of logically consistent but still useless models that simply suit someone's fancy.

quote
4.3:94.#20

> *A theory which is not refutable by any conceivable event is non-scientific. Irrefutability is not a virtue of a theory (as people often think) but a vice.*
>
> Karl Popper

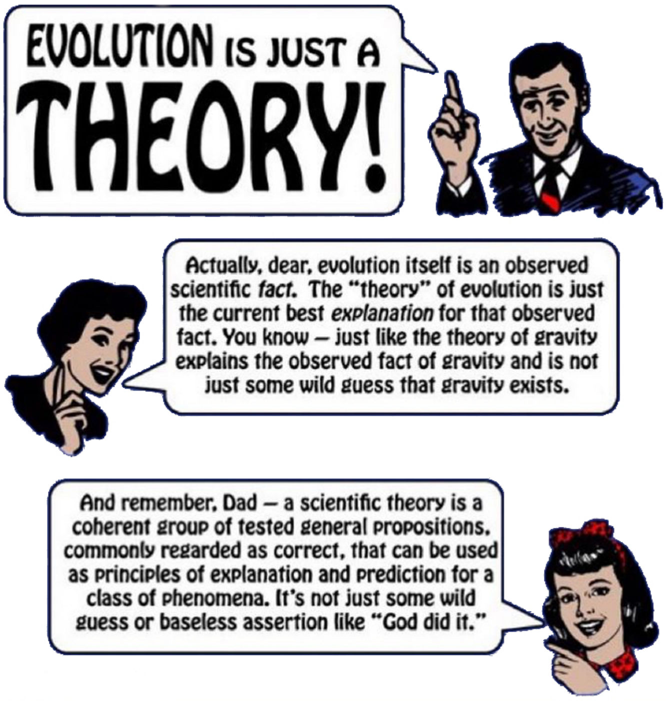
Logical Structure of Falsificationism



SCIENCE
NON-SCIENCE
STATEMENTS
Refutable
Non-Refutable
Experimentations
Corroborated
uncorroborated
Validated knowledge
Invalidated knowledge
non-scientific knowledge

Figure 4.16: **Logical structure of falsificationism**

Caution! There is no doubt that the exact sciences have yet an enormous prestige, even among their opponents because of their theoretical and practical success. It is certain that some scientists sometimes abuse of this prestige by showing a sense of superiority that is not necessarily justified. Moreover, it often happens that this same scientists expose in the popular literature, very speculative ideas as if they were very approved, and extrapolate their results outside the context in which they were tested (and ... under the hypotheses they were checked once...).



EVOLUTION IS JUST A THEORY!
Actually, dear, evolution itself is an observed scientific *fact*. The "theory" of evolution is just the current best *explanation* for that observed fact. You know – just like the theory of gravity explains the observed fact of gravity and is not just some wild guess that gravity exists.
And remember, Dad – a scientific theory is a coherent group of tested general propositions, commonly regarded as correct, that can be used as principles of explanation and prediction for a class of phenomena. It's not just some wild guess or baseless assertion like "God did it."

> **Remark**
>
> The two previous definitions are often included in the definition of "deductive sciences" or even "phenomenological science".

D3. We define as "rational science" the intellectual activity that starts from self-evident maybe biased claims and moves by rigorous first-order logical (see section Proof Theory page 163) arguments (that may be disconnected from the reality of experimental science) to a conclusion about some new logical truth (not related to experimental truth), this is named a "deduction" and may be or not wrong relatively to the conclusions of empirical science.

D4. We define as "engineering science" or "applied science" any set of knowledge or practices applied to the needs of human society such as electronics, chemistry, computer science, telecommunications, robotics, aerospace, biotechnology...

SCIENCE
ENGINEERING
SCIENCE IS ABOUT KNOWING
ENGINEERING IS ABOUT DOING

Remark

A common confusion by the population is to argue that scientists are the reason why guns and bombs exists. In facts physicists (and other "real" scientists) focus on the theories, the understanding of Nature, not on the business or political applications. The people that converts theories into business applications are "engineers" and engineers are not scientists. Engineers just convert science knowledge into business application in a genius way. That's what engineers are!

D5. We define as "science" any body of knowledge based on studies or observations of events whose interpretation has not yet been transcribed and verified with mathematical rigour, characteristic of previous sciences, but using comparative statistics. We include in this definition: medicine (we should however be careful because some parts of medicine are studying phenomena using mathematical descriptions such as neural networks or other phenomena associated with known physical causes), sociology, psychology, history, biology, etc.

Some teachers like to play with the word "science" as the acronym of (that's not stupid for college students): **S**olve, **C**reate, **I**nvestigate, **E**valuate, **N**otice, **C**lassify, **E**xperiment.

D6. We define a (modern) "scientist" as a professional owning a Doctorate and who systematically and daily gathers and uses reproducible research and experimental evidence, to make statistical hypothesis and test them using cutting edge scientific methods (like PhD level statistics or advanced reproducible numerical simulations), to gain and share peer-reviewed understanding and knowledge in famous scientific journals in a very specialized field of expertise.

The definition therefore exclude the huge majority of engineers (who don't publish in peer-reviewed papers and doesn't know how to analyse data using PhD statistical methods), laboratory assistants who just make experimental manipulations but don't make the hypothesis nor analyse the resulting measurements of their experiments but also medical doctors (see [500] and [190]) who only apply the results of scientific research but don't do any as specified above. Mathematicians are not excluded from this definition as their mathematical theories (proofs) are published in peer-reviewed papers and are reproduced (checked) independently by other mathematicians.

D7. We define as "soft science", "para-science" or "pseudo-science" any set of knowledge or practices that are currently based on non-verifiable and non-refutable facts (not scientifically reproducible) by experience or by mathematics. We include in this definition typically: astrology, theology, paranormal (which was demolished by zetetic science), graphology, justice[56], etc.

As some scientists say: *«It looks like science, it use the vocabulary of science... but that's not science at all.»*

Especially pseudo-sciences are characterized by:

- They start with a conclusion (belief), then work backwards to confirm
- They make sometimes unfalsifiable, vague or unobservable claims

---

[56] Indeed, for example in Switzerland, it is common that the cantonal Judge and the Federal Judge don't give the same judgement as that latter is non-scientific but rather subjectively based on the Judge experience of life

- They relied heavily on anecdotes, personal experiences, and testimonials
- They are hostile to criticism
- They use circular reasoning/arguments and other logical fallacies
- They use vague jargon to confuse and evade
- They use subtle strategies to change people minds (especially children)
- They make people feel special and unique
- They do cherry picking only on favourable evidence[57]
- They use non-reproducible/non-refutable methods with unrepeatable results
- They use bullshit-random language (technobabble) to impress the audience
- They use inconsistent and invalid logic
- They profess certainty, talk of "proof" with great confidence
- They claim there's a conspiracy to suppress or hide their ideas
- They go directly to the public, avoiding scientific scrutiny and consensus
- People working in the field are dogmatic and unyielding
- They highly monetize their books, videos (YouTube), conferences, etc.

Figure 4.17: Organized collection of irrational nonsense

---

[57] Typical especially for all thousand of religions and also pseudo-medicine like acupuncture that can be scientifically test by having a control group with no treatment and a placebo group treated with retractable needles...

And don't forget:

What can be asserted without scientific evidence can be dismissed without scientific evidence!!

D8. We define as a "scientific fact" a fact (i.e. simple eyewitness observation) that has been confirmed repeatedly using the scientific method (with modern apparatus, advanced statistical analysis, bias reduction, independent methods, independent teams and confusion variables control) and is accepted as true (although its truth is never final and must be continuously challenged!) by confirmation of meta-analysis (highest level of scientific evidence).

D9. We define as "phenomenological science" or "natural sciences", any science which is not included in the above definitions (history, sociology, psychology, zoology, biology, ...).

D10. "Scientism" is an ideology that considers experimental science is the only valid mode of knowledge, or, at least, superior to all other forms of interpretation in the world. In this perspective, there is no philosophical, religious or moral truths superior to scientific theories. Only account what is scientifically proven (i.e. evidence beyond reasonable doubt!).

D11. "Positivism" is a set of ideas that considers that only the analysis and understanding of facts verified by experience can explain the phenomena of the sensible world. Certainty is provided solely by the scientific experiment. He rejects introspection, intuition and metaphysical approach to explain any knowledge of the phenomena.

What is interesting about this doctrine is that it is certainly one of the few that requires people to have to think for themselves and to understand the environment around them by continually questioning everything and by never accepting anything as granted (...). In addition, the real sciences have this extraordinary property that they give the possibility to understand things beyond what we can see.

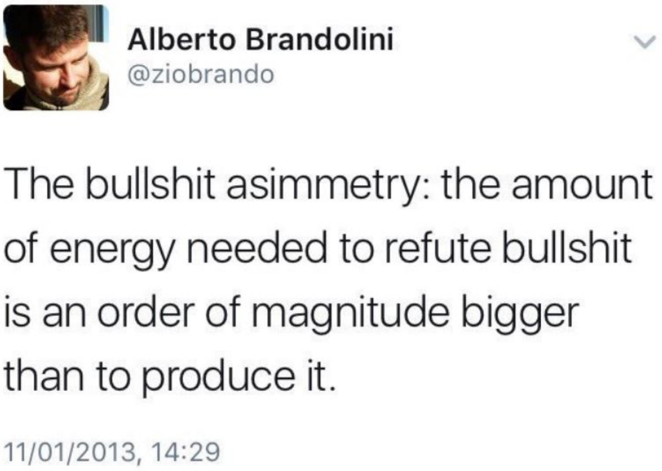
But, science is science, and nothing more: a certain ordering, not too bad success, things that no longer leads to the metaphysics as the time of Aristotle, but that does not pretend to give us the whole story on reality or even the bottom of visible things.

People must remember that Science is a robust cross-validated investigation method and NOT a belief system!!

Remark

A quite common bias is to argue that «*scientists believes in their actual models and the things they based their observations on*». That's totally wrong! Indeed, trained and real scientists are professionals (they are paid every month to do research and development - most of the time to find methods to reject existing theories - at least 30 to 70 hours per week after 5 to 7 years of graduate studies!) and at this level they are supposed to not be attached sentimentally to the models they're working on or things they used to make observations (even if some scientists - and sometimes some famous one - cannot control their cognitive biases!). The "*actual models*" and "*things they based their observations on*" are for professional scientists just "toy models" and "calibrated measurement tools" that seems actually to work well to explain and study our surrounding. When they have to build new models, this is because they are paid for! Not because they believe in them! There are absolutely no beliefs! Do you think that a garage owner really "believe" in it's wrench to work? He doesn't give a f**** about believing in it or not, it's just a well designed tool (maybe there is a better one?) that he uses to do his work conscientiously - sometimes with passion - to get his wage at the end of the month to pay his rent and food for his family!

And by the way... also don't forget that:



Alberto Brandolini
@ziobrando

The bullshit asimmetry: the amount of energy needed to refute bullshit is an order of magnitude bigger than to produce it.

11/01/2013, 14:29

Figure 4.18: **The Alberto Brandolini bullshit asymmetry law (source: Twitter)**

4.3.2 Terminology

The table of methods we presented earlier above (see page 51) contains terms that may perhaps seem unknown or barbarous for you. This is why it seems important to provide definitions of these and some other equally important that can avoid important confusion.

Definitions (#4.3.6):

D1. Beyond its negative sense, the idea of "problem" refers to the first step of the scientific method. Formulate a problem is also essential for its resolution and allows to properly understand what is the problem and see what needs to be resolved.

The concept of "problem" is intimately connected to the concept of "assumption" which will see the definition below.

D2. A "hypothesis" is always, in the context of a theory already established or underlying, a supposition awaiting confirmation or refutation that attempts to explain a group of facts or predict the onset of new facts.

Thus, a hypothesis can be at the origin of a theoretical problem that has to be resolved formally.

D3. The "postulate" or "assumption" in physics corresponds frequently to a principle (see definition below) which admission is required to establish a proof (we mean that this is a non-provable proposition).

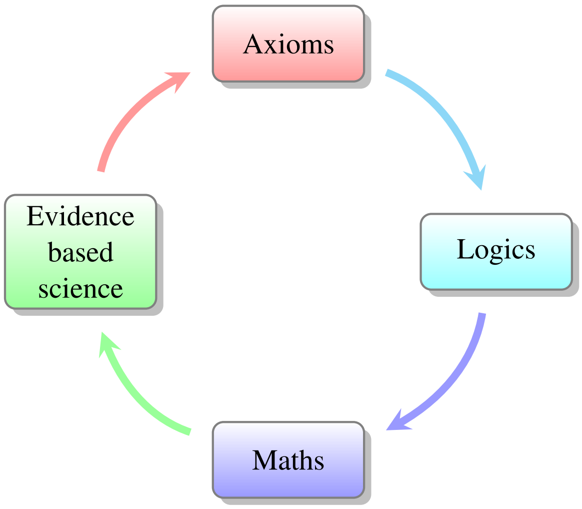
The mathematical equivalent (but in a more rigorous version) of the assumption is the "axiom" for which we will see the definition below.

D4. A "principle" (close parent of "postulate") is a proposal accepted as a basis for reasoning or a general theoretical guide line for reasoning that needs to be performed. In physics, it is also a general law governing a set of phenomena and verified by the accuracy of its consequences.

The word "principle" is used with abuse in small classes or engineering schools by teachers not knowing (which is very rare), or unwilling (rather common), or that can't because lack of time (almost exclusively) prove a relation.

The equivalent of the postulate or principle in mathematics is the "axiom" which we define as follows:

D5. Naively (in Euclid's time...) an "axiom" is a self-evident proposition or truth by itself which admission is necessary to establish a logical proof (this naive definition therefore does not require the resulting logical proof to be connected to reality!). In modern times, however, technically in first order logic (see page 131) an "axiom" is a formula $R(t_1,...,t_n)$ where R is a n-ary predicate symbol and the t_i are terms which admission is necessary and compliant with evidence based science to establish a logical proof.



We can show that an axiom is inconsistent with the remaining axioms of an axiomatic system by proving the negation of the axiom in the system. That is a form of disproof.

We can also prove an axiom by proving that it is implied by the remaining axioms in that same system.

In either case, we would then want to remove the axiom from the system.

If a system made of a single axiom contradicts reality, then it can be disproved by itself by experimental evidence. Like the axiom "every effect has a cause" is wrong in modern physics as we will see it during our study of Quantum Wave Theory (Casimir Effect) or also in our study of Nuclear Physics (radioactivity) or Cosmology (creation ex-nihilo of our universe).

If, however, the axiom is independent of the remaining axioms — very desirable, but we can't always show that — then it can be neither proven nor disproven in the system. Euclid's fifth postulate (that we will introduce during our study of Euclidean geometry at page 2553) is an example of that (as is the axiom of choice and the continuum hypothesis). Indeed, while axioms are accepted as true without proof, mathematicians often explore their implications and study their consequences. For example proofs related to the axiom of choice in Set Theory typically (see page 382) involve demonstrating its equivalence to other statements or exploring its applications. That's why we say that *the axiom of choice can neither be proved nor refuted in ZF* (which is all the ZFC axioms except the axiom of choice) and this result do not require the Gödel incompleteness theorems. And another famous example already mentioned just above is the 5th axiom of Euclidean geometry that has been proven wrong by Nikolai Lobachevsky in non-Euclidean geometries (it needs to be reformulated to hold!).

Remarks

R1. We could say that this is something we define as the truth for the speech that we argue, like a rule of the game, and that it does not necessarily a universal truth value in the sensitive world around us.

R2. Axioms must always be independent (one should not be able to be proved from the other) and non-contradictory (sometimes we also say that they must be "consistent").

D6. The "corollary" is a term unfortunately almost non-existent in physics (wrongly!) and that is in fact a proposal resulting from a truth already demonstrated. We can also say that a corollary is and obvious and necessary consequence of a theorem (or sometimes of a postulate in physics).

D7. A "lemma" is a proposal deduce from one or more assumptions or axioms and that for which the proof prepares this of a theorem.

Remark

The concept of "lemma" is also (and this is unfortunate) almost used only in the field of mathematics.

D8. A "conjecture" is a supposition or opinion based on the likelihood of a mathematical result.

Many conjectures have as little similar to lemmas, as they are checkpoints to obtain significant results.

D9. Beyond its weak conjecture sense, a "theory" or "theorem" (whose etimology means “a spectacle”, “subject for contemplation” or “proposition to be proved”) is a set articulated around a hypothesis and supported by a set of facts or developments that give it a positive content and make the hypothesis well-founded (or at least plausible in the case of theoretical physics).

D10. A "singularity" is an indeterminacy in a calculation That takes the appearance of a division by zero. This term is both used in mathematics and in physics.

D11. A "proof" is a set and sequence of mathematical procedures to use and follow to derive a result already known or not of a theorem, lemma or corollary (as already mentioned, this term should obviously be prohibited in experimental sciences as he doesn’t highlight the underlying level of evidence!).

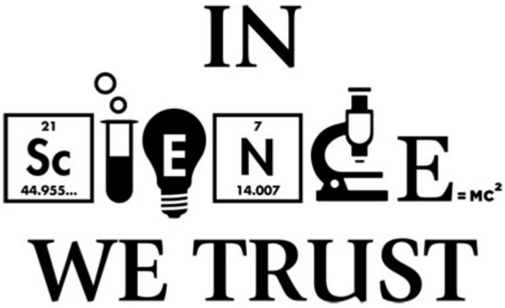
D12. If the word "paradox" etymologically means: contrary to common opinion, it is not by pure taste for provocation, but rather for solid reasons. A "sophism" meanwhile, is a deliberately provocative statement, a false proposition based on an apparently valid reasoning. Thus we speak about the "Zeno’s paradox" when in reality it is only a sophism. The paradox is not limited to falsity, but implies the coexistence of truth and falsity, so that one can no longer distinguish true and the false. The paradox appears as an unsolvable problem an "aporia".

Remark

It should be added that the well-knows paradoxes, by the questions they raised, have permitted significant advances to science and led to major conceptual revolutions in mathematics as in theoretical physics (the paradoxes on sets and on infinity in mathematical, and those at the base of relativity and quantum physics).

4.4. Science and Faith

We will see that in Science, a (scientific) theory is usually incomplete because it can not fully describe the complexity of the real world or because it does not predict what we don't know (excepted for Quantum Physics or General Relativity). It is thus for theories like the Cosmic Inflation Theory (see section Astrophysics page 5539) or the Evolution of Species (see sections Populations Dynamics page 7297 or Decision and Games Theory page 7376) because they are not reproducible in laboratories under identical conditions. But some other (scientific) theories are so accurate to predict physical phenomena that some people believe that mathematics is the nearest language with some kind of gods (at least for those who believe in a divinity[58]...) even if we know, as we have already mention it, that science is (should) be driven only by data and peer review publications.



We should distinguish between different scientific currents:

- "Realism" is a doctrine where physical theories have the aim to describe reality as it is in itself, in its unobservable components.
- "Instrumentalism" is a doctrine where physical theories are only tools to predict observations but do not describe reality itself.
- "Fictionalism" is the doctrine where the content repository (principles and postulates) of physical theories is just an illusion, useful only to ensure the linguistic articulation of the fundamental equations.

Even if today the scientific theories are sponsored by many specialists, alternative models have valid arguments and we can not totally dismiss them. However, the creation of the World in six or seven days as described in some books is difficult to accept, and many believers recognize that a literal reading of religious books is not compatible with the current state of our knowledge and that it is more prudent to interpret it as a parable (even if their own books forbids explicitly such an intellectual exercise...!). If Science never provides definitive answer, it is no longer possible to ignore it!

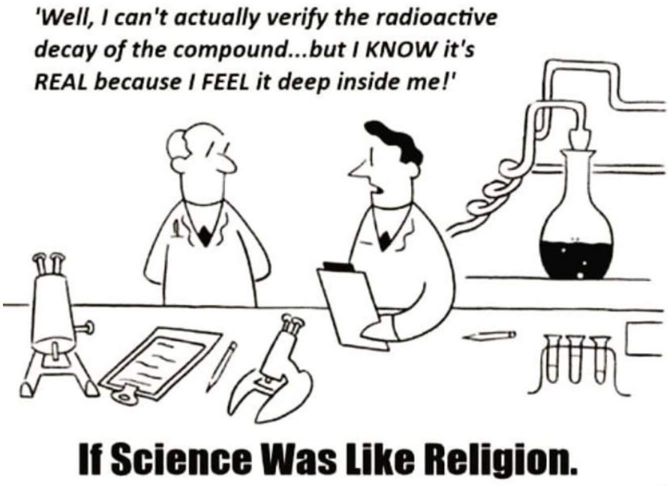
---

[58] Keep in mind that according to what we have seen before, the existence of a Divinity is an "Hypothesis" at the opposite of the Evolution of Species for example that is a "Theory" (see [492])!

Faith (whether religious, superstitious, pseudo-scientific or other not data driven) on the contrary is intended to provide absolute truths of a different nature as it is a personal unverifiable belief (for example, Science requires proofs to be evidence based, religions requires beliefs to be proved...). This is why many people say that «*Science adjusts views based on what's observed when Faith is the denial of observation so that belief can be preserved*».... In fact, one of the functions of religion is to give meaning to the phenomena that can not be explained rationally with actual knowledge[59]. Progress of knowledge trough Science therefore cause sometimes (...) questioning the religious dogma[60].

quote
4.4:104.#21

> *SCIENCE is not defined by what we believe. IT IS NOT a belief system. It has no religious doctrine! It's just an intellectual investigation method that rejects claims that have no supporting experimental reproducible evidence.*



'Well, I can't actually verify the radioactive decay of the compound...but I KNOW it's REAL because I FEEL it deep inside me!'
If Science Was Like Religion.

Conversely, except try to impose his own faith (which is nothing but a subjective and intimate personal conviction) to others, we must defy the natural temptation to characterize scientifically proven fact extrapolations of scientific models beyond their scope.

The word "Science" is, as we have already mentioned above, increasingly used to argue that there is a scientific evidence where there is only a belief (some web pages like this proliferate always more and more and especially to get followers and a lot of clicks on the Internet). According to its detractors it is, for example, the case of the movement of Scientology (but there are many others). According to them, we should rather speak about "occult sciences".

---

[59] This was the case with the rain, the thunder, diseases, stars, comets, earthquakes, volcanic eruptions, birth, evolution, etc. a few hundred years ago and is often designated by scientists under the name of "argument of ignorance"

[60] When theists say that a god must exist because Earth is "perfectly" place for life, they assume that their god is restricted to placing life where it could naturally occur anyway...

The occult sciences and traditional sciences exist since antiquity; they consist on a series of mysterious knowledge and practices designed to penetrate and dominate the secrets of nature. Over the past centuries, they have been progressively excluded from science. The philosopher Karl Popper has for a long time questioned himself about the nature of the demarcation between science and pseudoscience. After noticing that it is possible to find observations to confirm almost any theory, he proposes a methodology based on falsifiability. A theory must according to him, to deserve the adjective "scientific", guarantee the impossibility of some events. It becomes therefore refutable, so (and only then) capable of integrating science. It would suffice to observe any of these events to invalidate the theory, and therefore take the way to improving it.

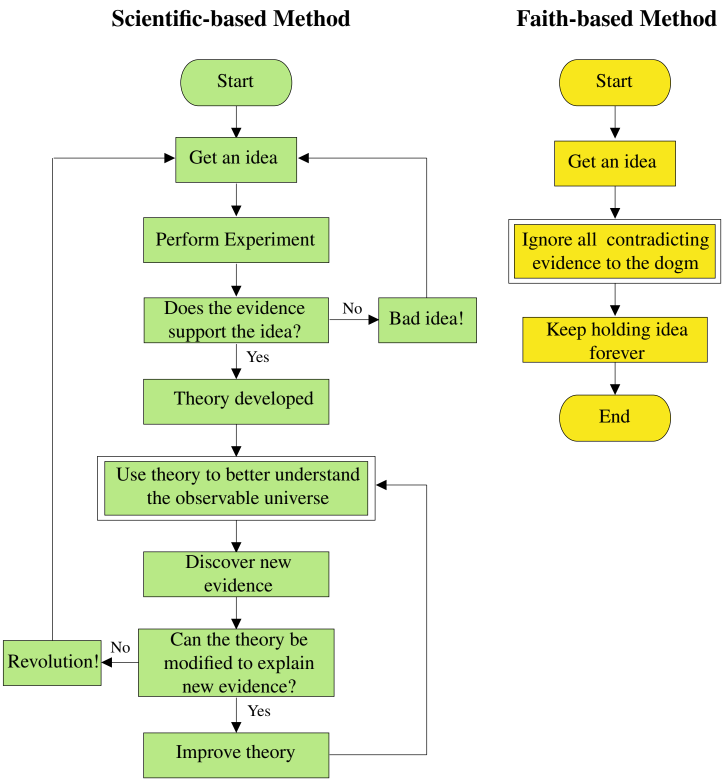
And also let us notice that major difference between scientific textbooks and religious books is that if you destroyed that latter, in a thousand year's time that wouldn't come back just as it was. Whereas if we took every science textbook and every fact and destroyed them all, in a thousand years they'd all be back. Because all the same tests would lead to the same results again!

> ❞ *The reason there is a conflict between science and religions is that science keep disproving the things religions claims to be true or accurate.* ❞

quote 4.4:105.#22

Remark

If science, and over everything MATHEMATICS are the language of a God, then why are all holy books written without maths? Oh, umh... we know why!



Scientific-based Method **Faith-based Method**

Start
Get an idea
Perform Experiment
Does the evidence support the idea?
No
Bad idea!
Yes
Theory developed
Use theory to better understand the observable universe
Discover new evidence
Can the theory be modified to explain new evidence?
No
Revolution!
Yes
Improve theory
Start
Get an idea
Ignore all contradicting evidence to the dogm
Keep holding idea forever
End

This is important because every one of the endless series of pseudo-proofs of the existence of various gods that has been proposed, from antiquity to the present day, is automatically a failure because, as already mentioned, a logical deduction tells us nothing that is not already embedded in its premises. All logic can do for us is test the self-consistency of those premises. There is only one reliable way that humans have discovered so far to obtain knowledge they do not already possess: observation! And science is the methodical collecting of observations and the building and testing of models to describe those observations. Without falsification science would be an anarchy of logically consistent but still useless models that simply suit someone's fancy!

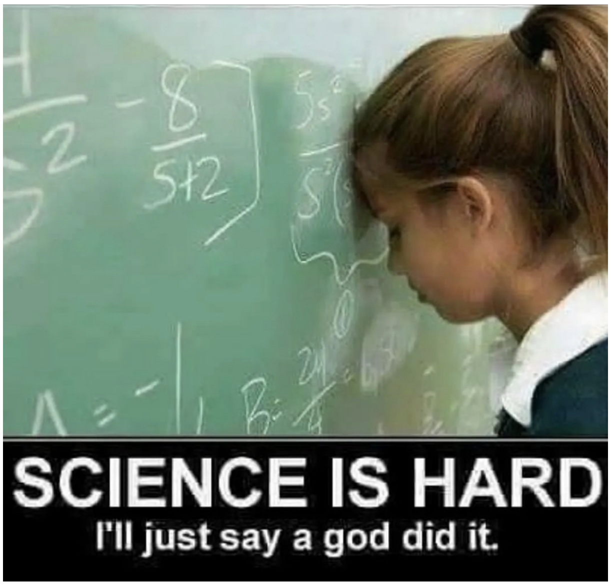
quote
4.4:106.#23

> ❞ *Religion is the practice of using nonsense, in order to explain ignorance.* ❞

Furthermore, religion has had thousands of years to provide evidence that any god exist. Yet can theists manage no better than: «*YOU JUST WAIT UNTIL YOU'RE DEAD*». That tells a lot... all the more because if gods were real they wouldn't need people to argue their existence! And if theists really value faith over science then they can prove it easily: the next time they get sick they can go to a church instead of going to the hospital!

quote
4.4:106.#24

> ❞ *A scientist will read dozens of books in his lifetime, but still known that he has a lot more to learn. A religious fanatic barely reads one book, and think that they know it all.* ❞



SCIENCE IS HARD
I'll just say a god did it.

The reader must also know that at the opposite of a common myth by scientifically illiterate people, any phenomenon or assumption (even supernatural!) if well defined can be tested by the scientific method. That's why we have (among many others) scientific evidence that prayers don't provide any therapeutic effect better than a placebo. See for example about supernatural stuff the following paper *Study of the Therapeutic Effects of Intercessory Prayer (STEP) in cardiac bypass patients: a multicenter randomized trial of uncertainty and certainty of receiving intercessory prayer* [51] for a quite good scientific protocol and analysis or the following paper *Positive therapeutic effects of intercessory prayer in a coronary care unit population* [84] for a typical bad scientific protocol and analysis. There exist also a few meta-analysis on this supernatural topic...

> ❞ *It doesn't matter if a great scientist was religious. What matters is that none of them ever proved their god exists!* ❞

A proposed origin language from Eurasia that unites the majority of world languages. It is speculated that the people who spoke this ancient tongue were practitioners of shamanism (a belief in a spirit world that permeates all nature).
This graphic illustrates how this Nostratic faith may have spread out across the continents, following the path of human migration, evolving into the multitude of religions we are familiar with today.
Animism: 100,000 BCE
It is possible the earliest sign of religious activity can be traced back to the Middle Palaeolithic where our distant ancestors began to bury their dead in a ritualistic manner, and create symbolic artefacts (early signifiers of spiritual activity).
---- Influenced by another religion
—— Adapted from another religion
PLEASE NOTE ; due to the vague nature of mythology, the origins to many of these faiths are estimates only and should not be counted as fact. This chart can only offer an approximation to the founding dates of ancient religions.

Figure 4.19: **Evolutionary tree of religions (author: Simon E. Davies)**

Facts enrages believers, who prompts them to solipsism. Their only way to defend beliefs that are not concordant with scientific data is to challenge reality itself (that's why before debating with such people scientists have to agree with them about a definition of "reality" otherwise any debate is pointless)! So every time you argue with believers, because they can't address the facts they will attack the epistemology. As it is as if their position is so weak that their gods couldn't be real unless reality isn't...

quote 4.4:108.#26

> *Faith leads human astray and is a function of his lack of scientific knowledge.*

4.4.1 Baloney detection kit

Through their training, scientists are equipped with what Carl Sagan name the "baloney detection kit" or "bullshit detection kit" that is a set of cognitive tools and techniques that fortify the mind against penetration by falsehoods and to draw boundaries between science and pseudo-science. It isn't merely a tool of science, it contains invaluable tools of healthy scepticism that apply just as elegantly, and just as necessarily, to everyday life. By adopting the kit, we can all shield ourselves against clueless guile and deliberate manipulation.

There are many version of these detection tool but here is a quite complete one (but still incomplete by construction) a proposed by Michael Shermer (founding publisher of Skeptic Magazine and author of *The Borderlands of Science*):

01 ***How reliable is the source of the claim?***

Pseudo-scientists often appear quite reliable, but when examined closely, the facts and figures they cite are distorted, taken out of context or occasionally even fabricated. Of course, everyone makes some mistakes. And as historian of science Daniel Kevles showed so effectively in his book The Baltimore Affair, it can be hard to detect a fraudulent signal within the background noise of sloppiness that is a normal part of the scientific process. The question is, Do the data and interpretations show signs of intentional distortion? When an independent committee established to investigate potential fraud scrutinized a set of research notes in Nobel laureate David Baltimore's laboratory, it revealed a surprising number of mistakes. Baltimore was exonerated because his lab's mistakes were random and nondirectional... So in science, there are no authorities and therefore claims are also not proofs (believing in something does not make it true!!!). At most, there are experts!

02 ***Does this source often make similar claims?***

Pseudo-scientists have a habit of going well beyond the facts. Flood geologists (creationists who believe that Noah's flood can account for many of the Earth's geologic formations) consistently make outrageous claims that bear no relation to geological science. Of course, some great thinkers do frequently go beyond the data in their creative speculations. Thomas Gold of Cornell University is notorious for his radical ideas, but he has been right often enough that other scientists listen to what he has to say. Gold proposes, for example, that oil is not a fossil fuel at all but the by-product of a deep, hot biosphere (micro-organisms living at unexpected depths within the crust). Hardly any Earth scientists with whom I have spoken think Gold is right, yet they do not consider him a crank. Watch out for a pattern of fringe thinking that consistently ignores or distorts data.

03 ***Have the claims been verified by another source?***

Typically pseudo-scientists make statements that are unverified or verified only by a source within their own belief circle. We must ask, Who is checking the claims, and even who is checking the checkers? The biggest problem with the cold fusion debacle, for instance, was not that Stanley Pons and Martin Fleischman were wrong. It was that they announced their spectacular discovery at a press conference before other laboratories verified it. Worse, when cold fusion was not replicated, they continued to cling to their claim. Outside verification is crucial to good science.

04 ***How does the claim fit with what we know about how the world works?***

An extraordinary claim must be placed into a larger context to see how it fits. When people claim that the Egyptian pyramids and the Sphinx were built more than 10,000 years ago by an unknown, advanced race, they are not presenting any context for that earlier civilization. Where are the rest of the artefacts of those people? Where are their works of art, their weapons, their clothing, their tools, their trash? Archaeology simply does not operate this way.

05 ***Has anyone gone out of the way to disprove the claim, or has only supportive evidence been sought?***

This is the "confirmation bias" (we will come back on cognitive biases in the section of Decision Theory page 7381), or the tendency to seek confirmatory evidence and to reject or ignore disconfirmatory evidence. The confirmation bias is powerful, pervasive and almost impossible for any of us to avoid. It is why the methods of science that emphasize checking and rechecking, verification and replication, and especially attempts to falsify a claim, are so critical.

06 ***Does the preponderance of evidence point to the claimant's conclusion or to a different one?***

The theory of evolution, for example, is "proved" through a convergence of evidence from a number of independent lines of inquiry. No one fossil, no one piece of biological or palaeontological evidence has "evolution" written on it; instead tens of thousands of evidentiary bits add up to a story of the evolution of life. Creationists conveniently ignore this confluence, focusing instead on trivial anomalies or currently unexplained phenomena in the history of life.

07 ***Is the claimant employing the accepted rules of reason and tools of research, or have these been abandoned in favour of others that lead to the desired conclusion?***

A clear distinction can be made between SETI (Search for Extraterrestrial Intelligence) scientists and UFOlogists. SETI scientists begin with the null hypothesis that ETIs do not exist and that they must provide concrete evidence before making the extraordinary claim that we are not alone in the universe. UFOlogists begin with the positive hypothesis that ETIs exist and have visited us, then employ questionable research techniques to support that belief, such as hypnotic regression (revelations of abduction experiences), anecdotal reasoning (countless stories of UFO sightings), conspiratorial thinking (governmental cover-ups of alien encounters), low-quality visual evidence (blurry photographs and grainy videos), and anomalistic thinking (atmospheric anomalies and visual misperceptions by eyewitnesses).

08 ***Is the claimant providing an explanation for the observed phenomena or merely denying the existing explanation?***

This is a classic debate strategy-criticize your opponent and never affirm what you believe to avoid criticism. It is next to impossible to get creationists to offer an explanation for life (other than "God did it"). Intelligent Design (ID) creationists have done no better, picking away at weaknesses in scientific explanations for difficult problems and offering in their stead. "ID did it." This stratagem is unacceptable in science.

(09) ***If the claimant proffers a new explanation, does it account for as many phenomena as the old explanation did?***

Many HIV/AIDS sceptics argue that lifestyle causes AIDS. Yet their alternative theory does not explain nearly as much of the data as the HIV theory does. To make their argument, they must ignore the diverse evidence in support of HIV as the causal vector in AIDS while ignoring the significant correlation between the rise in AIDS among haemophiliacs shortly after HIV was inadvertently introduced into the blood supply.

⑩ ***Do the claimant's personal beliefs and biases drive the conclusions, or vice versa?***

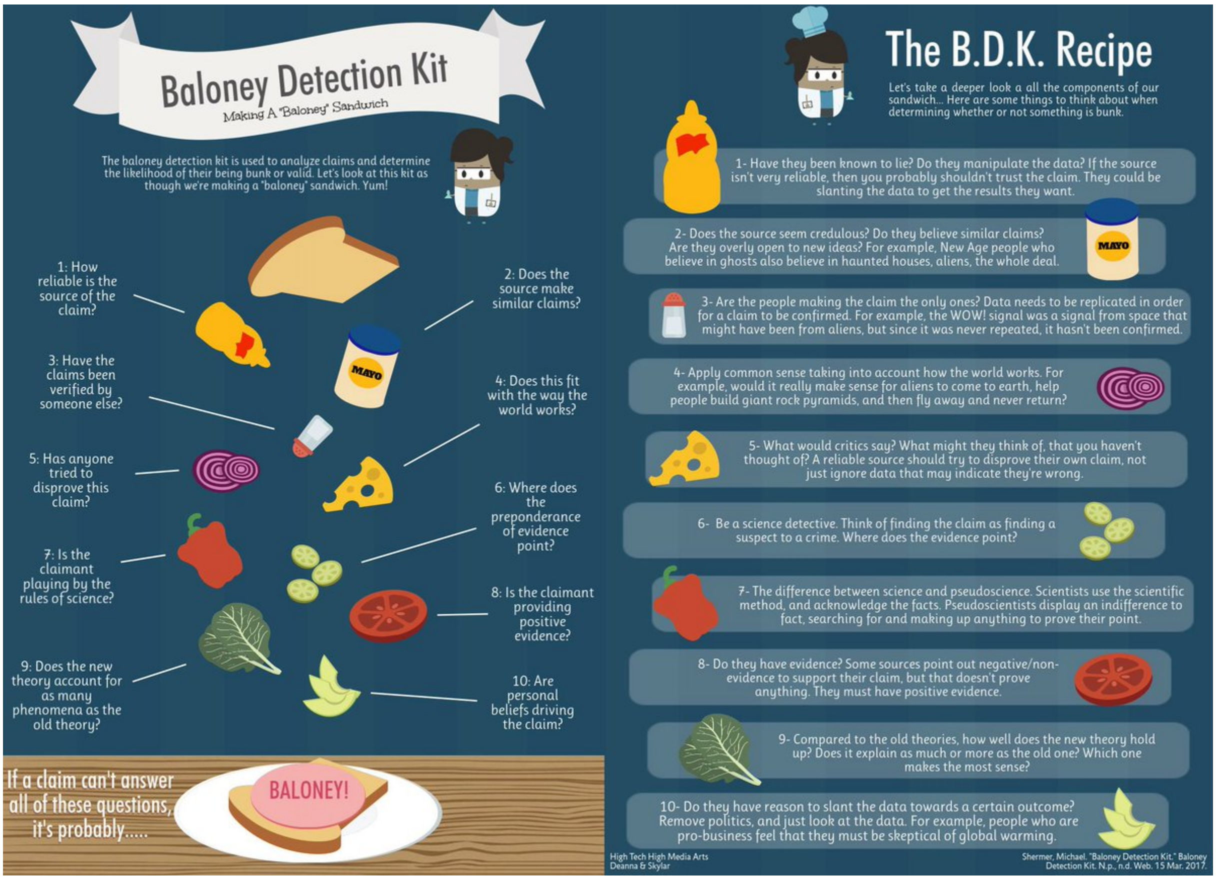
All scientists hold social, political and ideological beliefs that could potentially slant their interpretations of the data (this is a "confirmation bias" also named "cherry picking" that is also by non-scientists the main cause of rejecting science results and tools), but how do those biases and beliefs affect their research in practice? Usually during the peer review system, such biases and beliefs are rooted out, or the paper or book is rejected.

Some humans and especially believers (not just religious believers but on any subject for which there is no experimental evidence beyond reasonable doubt) are good at what is named "concordism". The underlying idea of concordism is to interpret texts or find random analogies in Nature (obviously having zero knowledge of combinatorics and probabilities) to justify that all the inventions or discoveries of modern science have been announced in their "holy" books or invented by people belonging to the same belief group as themselves hundreds or thousands of years before others. Obviously all this masked under a hazy rhetoric, analogies that make no sense (compare statistical studies with simple texts...), no statistical methodology, omitting to quote contradictory facts or conclusions, and with a total absence of cross-referencing sources and peer review! This obscurantism at its finest!!!

It must be noted that this concordist approach is the prerogative of people with little education or indoctrinated since childhood (plus those suffering from mental disorders for various reasons) who are not able to identify their own biases, who are closed to any contradiction, and who are not capable of identifying the real complexity (multifactoriality) and the nuances of even a simple subject (they tend to binarize everything in True/False).

> ❞ *You can beat 100,000 scholars with one fact, but you will very likely never beat an idiot even with 100 facts.* ❞

quote 4.4:111.#27



Baloney Detection Kit

Making A "Baloney" Sandwich

The baloney detection kit is used to analyze claims and determine the likelihood of their being bunk or valid. Let's look at this kit as though we're making a "baloney" sandwich. Yum!

1: How reliable is the source of the claim?

2: Does the source make similar claims?

3: Have the claims been verified by someone else?

4: Does this fit with the way the world works?

5: Has anyone tried to disprove this claim?

6: Where does the preponderance of evidence point?

7: Is the claimant playing by the rules of science?

8: Is the claimant providing positive evidence?

9: Does the new theory account for as many phenomena as the old theory?

10: Are personal beliefs driving the claim?

If a claim can't answer all of these questions, it's probably.....

The B.D.K. Recipe

Let's take a deeper look a all the components of our sandwich... Here are some things to think about when determining whether or not something is bunk.

1- Have they been known to lie? Do they manipulate the data? If the source isn't very reliable, then you probably shouldn't trust the claim. They could be slanting the data to get the results they want.

2- Does the source seem credulous? Do they believe similar claims? Are they overly open to new ideas? For example, New Age people who believe in ghosts also believe in haunted houses, aliens, the whole deal.

3- Are the people making the claim the only ones? Data needs to be replicated in order for a claim to be confirmed. For example, the WOW! signal was a signal from space that might have been from aliens, but since it was never repeated, it hasn't been confirmed.

4- Apply common sense taking into account how the world works. For example, would it really make sense for aliens to come to earth, help people build giant rock pyramids, and then fly away and never return?

5- What would critics say? What might they think of, that you haven't thought of? A reliable source should try to disprove their own claim, not just ignore data that may indicate they're wrong.

6- Be a science detective. Think of finding the claim as finding a suspect to a crime. Where does the evidence point?

7- The difference between science and pseudoscience. Scientists use the scientific method, and acknowledge the facts. Pseudoscientists display an indifference to fact, searching for and making up anything to prove their point.

8- Do they have evidence? Some sources point out negative/non-evidence to support their claim, but that doesn't prove anything. They must have positive evidence.

9- Compared to the old theories, how well does the new theory hold up? Does it explain as much or more as the old one? Which one makes the most sense?

10- Do they have reason to slant the data towards a certain outcome? Remove politics, and just look at the data. For example, people who are pro-business feel that they must be skeptical of global warming.

High Tech High Media Arts
Deanna & Skylar

Shermer, Michael. "Baloney Detection Kit." Baloney Detection Kit. N.p., n.d. Web. 15 Mar. 2017.

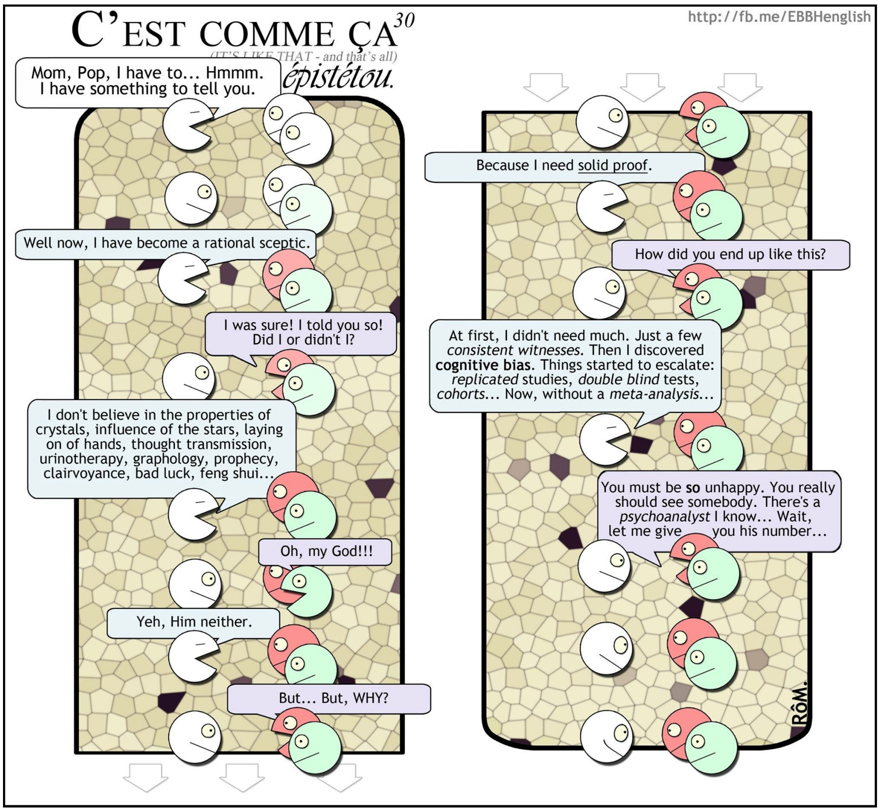
By fine tuning we can go far more about reasoning fallacies. Here is a small non-exhaustive list:

1. Ad hominem: An ad hominem argument attacks the messenger, not the message itself.
2. Argument from authority: Argument that relies on the identity of an authority rather than the components of the argument itself.
3. Argument from adverse consequences: Saying that because the implications of a statement being true would generate negative results, it must not be true.
4. Appeal to ignorance: If something is not known to be false, it must be true.
5. Special pleading: Stating a universal principle, then insisting that it doesn't apply to your assertions for some reason.
6. Begging the question/ assuming the answer: This occurs when a statement has an unproven premise. It is also named "circular reasoning" or "circular logic".
7. Observational selection: Looking at only positive evidence while ignoring the negative and vice versa.
8. Statistics of small numbers: Using small numbers in order to report large percentage increases.

9. Misunderstanding of the nature of statistics: Ignorance about central statistical assumptions and the definition of metrics (the confusion of correlation and causation, the sample size and hate of maths bias are well known example).
10. Post hoc, ergo propter hoc: Basing an effect on a cause only on the basis of chronology.
11. Excluded middle, or false dichotomy: Portraying an issue or argument as having only two options and no spectrum in between.
12. Short-term vs. long-term: Assuming a current trend has remained constant throughout its history and will continue to do so in the future, even though no evidence suggests such an extrapolation is justified.
13. Slippery slope, related to excluded middle: Saying something is wrong because it is next to or loosely related to something wrong.
14. Suppressed evidence and half-truths: Drawing an unwarranted conclusion from premises that are at least in part correct.
15. Weasel words: The usage of vague, non-specific references.

In addition to teaching us what to do when evaluating a claim to knowledge, any good baloney detection kit must also teach us what not to do. It helps us recognize the most common and perilous fallacies of logic and rhetoric. Many good examples can be found in religion and politics, because their practitioners are so often obliged to justify two contradictory propositions.

Finally, we would like to quote Antoine Lavoisier: «*The physicist may also, in the silence of his laboratory and his cabinet, perform patriotic functions; he can thanks to his works reduce the mass of evils which afflict happiness and, had he not, contributed by the new roads that he opened to himself, only to delay of a few years, of a few days, the average life of humans, he could also aspire to the glorious title of benefactor of humanity.*»



C'EST COMME ÇA[30]
(IT'S LIKE THAT - and that's all)
épistétou.
http://fb.me/EBBHenglish
Mom, Pop, I have to... Hmmm. I have something to tell you.
Well now, I have become a rational sceptic.
I was sure! I told you so! Did I or didn't I?
I don't believe in the properties of crystals, influence of the stars, laying on of hands, thought transmission, urinotherapy, graphology, prophecy, clairvoyance, bad luck, feng shui...
Oh, my God!!!
Yeh, Him neither.
But... But, WHY?
Because I need solid proof.
How did you end up like this?
At first, I didn't need much. Just a few consistent witnesses. Then I discovered cognitive bias. Things started to escalate: replicated studies, double blind tests, cohorts... Now, without a meta-analysis...
You must be so unhappy. You really should see somebody. There's a psychoanalyst I know... Wait, let me give you his number...
RôM.

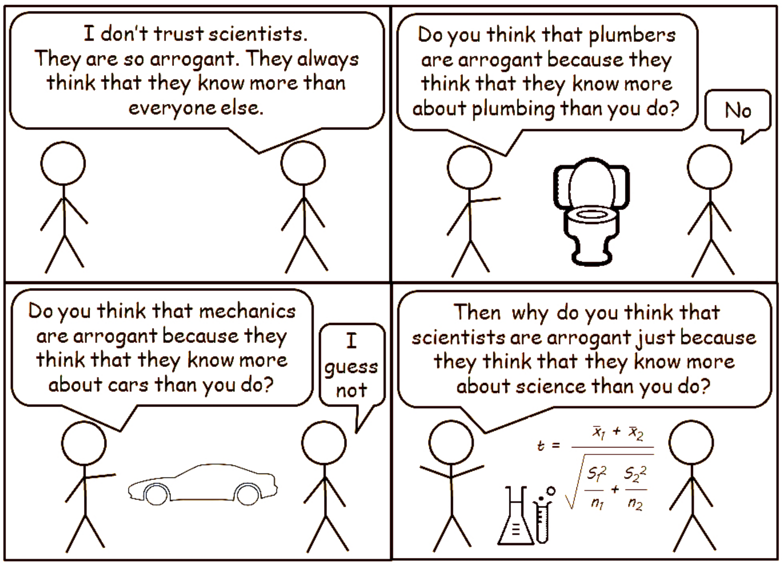
Caution! Be extremely careful in life with non peer review textbooks (or videos/podcasts) distributed by non-academic publisher whose content use pleasant story telling, psychological techniques (beautiful design, well-chosen music, etc.), flattery and extraordinary claims (without referencing to a quite large bibliography of empirical evidence reported in papers that respect the scientifical publication rules as given at page 70) to manipulate you and get your money by selling various services (books, events, trainings, etc.) and unfalsifiable promises! Science at the opposite will mostly provide you highly complex unpleasant knowledge and information and also (unperfect) tools that work and are useful in real life...

4.5. Scientific communication backfire

Another point that may be important to highlight about scientific communication: Scientists need to stop thinking that explaining science will fix all issues from the world and people's biases (at best they can be mitigated a little bit)! Especially nowadays where conspiracies about flat Earth, vaccines, climate change, Moon landing, etc. spread out thanks to social networks and that many mainstream media don't know how to communicate scientific papers correctly (or do it on purpose just for clickbait...). For example, in 12010 (holocene calendar) a landmark study (see [422]) showed that confronting people with hard evidence can backfire, making them more entrenched in their biases and misperceptions.

The main reasons are as follow and apply outside the case where people come listen to scientists in the context of a conference or seminar or participate on scientific debate on social networks live stream:

1. Some people don't really want to listen about the Scientific Method especially when they never asked themselves «what is the level of evidence?», «is it the best method?», «is this not a bias?». Moreover if they use the argument «...their science...» just to point out that scientists may be wrong (without knowing that scientists like to be wrong and that's how science works...!) about a given topic during a debate or discussion, correcting this fallacy may just take such individuals out of their comfort zone and make them even more hate (or reject) science and therefore we get a backfire effect.



I don't trust scientists. They are so arrogant. They always think that they know more than everyone else.
Do you think that plumbers are arrogant because they think that they know more about plumbing than you do?
No
Do you think that mechanics are arrogant because they think that they know more about cars than you do?
I guess not
Then why do you think that scientists are arrogant just because they think that they know more about science than you do?
$t = \frac{\bar{x}_1 + \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$

thelogicofscience.com

2. Most humans are full of biases and they don't like to admit that this is a true fact as they assume the human is the top species of evolution and therefore could have such biases.... So when you explain such people that they have biases, you just point out that they are not reliable in some aspect of their observation of Nature. Speak about bias only if people ask you to do so or you will very likely get again a backfire effect!

3. A significant percentage of people believe that their personal experience is more robust than the hundred of years of peer-review, tests, checks of the "scientific method" that has seems so far, if not THE best, at least the best one investigation method of the Nature we know nowadays.

Remark

"Anecdotally" there are also many other reasons (humanly understandable...) why science or members of the scientific community are defamed, such as (non-exhaustive list in random order) the fact that: popular science uses analogies that are distressing false equivalences and annoys some individuals, scientific communication uses sometimes religious vocabulary (such as "God particle" instead of "Higgs boson") or unsuitable vocabulary (such as "Big Bang theory" instead of "cosmic inflation theory") to describe phenomena and this generates a mixture of genres that strongly irritates some individuals, science often imposes itself in small classes only with rhetoric and without mathematical proofs or experimental evidence which can make it confused with a religious dogma and therefore a belief which tends to conflict with people with other beliefs, quantum physics is non-intuitive (non-locality, phenomena without cause, spontaneous appearance of vacuum energy, etc.) and greatly destabilizes the knowledge frame of the macroscopic world, some people have been ejected from the school system because of a bitter failure in the scientific branches and they find themselves marked for life (impossibility of doing the job of their dreams), science contradicts/challenges the dogmas of all religions/beliefs (evolution, genesis, non-existence of the soul, mental illnesses of pseudo-prophets, false miracles, etc.), scientific publications have destroyed (or put into puerile) the business of certain charlatans (clairvoyance, homeopathy, physiotherapy, acupuncture, etc.), some individuals have lost their jobs because of technological evolution falsely attributed to science (while it is the engineers who must find practical applications for science), some individuals have experienced a serious medical error and associate Medicine with Science (while medicine is an art and that doctors are not scientists), the worldview of some individuals is Manichean while science is probabilistic and certainties ("absolute truths") are more the exception than the rule, science is iterative and constantly questions itself and evolves destabilizes some people who need stability/certainties in their lives, some are jealous of the high salaries of scientists or their high level of postgraduate university training (anti-intellectualism), some individuals think that it is science and scientists who develop nuclear weapons and bombs while they are mostly engineers (and again: engineers are not scientists!), the results of science are above human legal laws is poorly accepted by some, the loss of loved ones or serious accidents that people cannot simply associate with the hazard (probabilities) and then need to find a culprit to designate, some individuals are afraid of developments in engineering often wrongly associated with science (artificial intelligence, genetic modifications, injections of treatments), Western science has given Western names to certain theorems which were not discovered by Westerners (this causes jealousy in certain cultures), scientific culture is over-represented in certain countries which have entered into wars or competition with other countries and have totally crushed them with their techno-scientific advances, etc. etc. etc.!

> *No amount of peer-reviewed evidence will ever persuade an idiot, all the more if the latter is scientifically illiterate and doesn't master top level statistical calculations and the subtleties of the scientific method.*

quote
4.5:117.#28

Now let us quote some paragraphs of an excellent article of Tim Requarth as it is almost perfect:

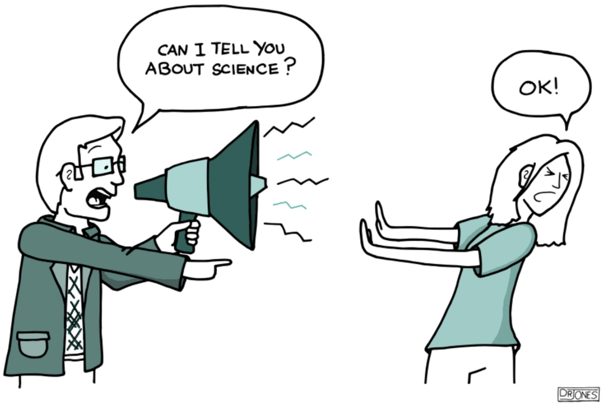
«The theory many scientists seem to swear by is technically known as the deficit model, which states that people's opinions differ from scientific consensus because they lack scientific knowledge. In 12010 (holocene calendar), Dan Kahan, a Yale psychologist, essentially proved this theory wrong. He surveyed over 1,500 Americans, classifying each person's "cultural worldview" on a scale that roughly correlates with politically liberal or conservative. He then assessed each person's scientific literacy with questions such as "True or False: Electrons are smaller than atoms". Finally, he asked them about climate change. If the deficit model were correct, Kahan reasoned, then people with increased scientific literacy, regardless of worldview, should agree with scientists that climate change poses a serious risk to humanity.

That's not what he found. Instead, Kahan found that increased scientific literacy actually had a small negative effect: The conservative-leaning respondents who knew the most about science thought climate change posed the least risk. Scientific literacy, it seemed, increased polarization. In a later study, Kahan added a twist: He asked respondents what climate scientists believed. Respondents who knew more about science generally, regardless of political leaning, were better able to identify the scientific consensus-in other words, the polarization disappeared. Yet, when the same people were asked for their own opinions about climate change, the polarization returned. It showed that even when people understand the scientific consensus, they may not accept it.

> *Having no postgraduate education on this subject, nor having any biases and having done no research in a lab at a professional level whatsoever, I don't understand it. Therefore, it doesn't make sense and is false!*
>
> Average social network user

quote
4.5:117.#29

The takeaway is clear: Increasing science literacy alone won't change minds. In fact, well-meaning attempts by scientists to inform the public might even backfire. Presenting facts that conflict with an individual's worldview, it turns out, can cause people to dig in further. Psychologists, aptly, dubbed this the "backfire effect".



CAN I TELL YOU ABOUT SCIENCE?
OK!
DRJONES

Figure 4.20: **source:** https://www.ratbotcomics.com, **author: Dr. Jones**

If scientists simply want to explain science to a curious audience, disseminate their research more broadly, or write for fun, this doesn't matter much. But if scientists are motivated to change minds-and many enrolled in science communication workshops do seem to have this goal-they will be sorely disappointed.

That's not to say scientists should return to the bench and keep their mouths shut. They should just realize that closing the "information gap" isn't the goal. And instead, they need to learn how to communicate science strategically.

There are obvious reasons why science communication is a necessary and worthwhile endeavour, but a huge one is that there's a politically motivated push to destabilize scientific authority. At a Heartland Institute conference last month, Lamar Smith, the Republican chairman of the House science committee, told attendees he would now refer to "climate science" as "politically correct science", to loud cheers. This lumps scientists in with the nebulous "left" and, as Daniel Engber pointed out here in Slate about the upcoming March for Science, rebrands scientific authority as just another form of elitism.

Is it any surprise, then, that lectures from scientists built on the premise that they simply know more (even if it's true) fail to convince this audience? Rather than fill the information deficit by building an arsenal of facts, scientists should instead consider how they deploy their knowledge. They may have more luck communicating if, in addition to presenting facts and figures, they appeal to emotions. This could mean not simply explaining the science of how something works but spending time on why it matters to the author and why it ought to matter to the reader. Research also shows that science communicators can be more effective after they've gained the audience's trust. With that in mind, it may be more worthwhile to figure out how to talk about science with people they already know, through, say, local and community interactions, than it is to try to publish explainers on national news sites. And they might consider writing op-eds for their local papers, focusing on why science matters to their particular communities.

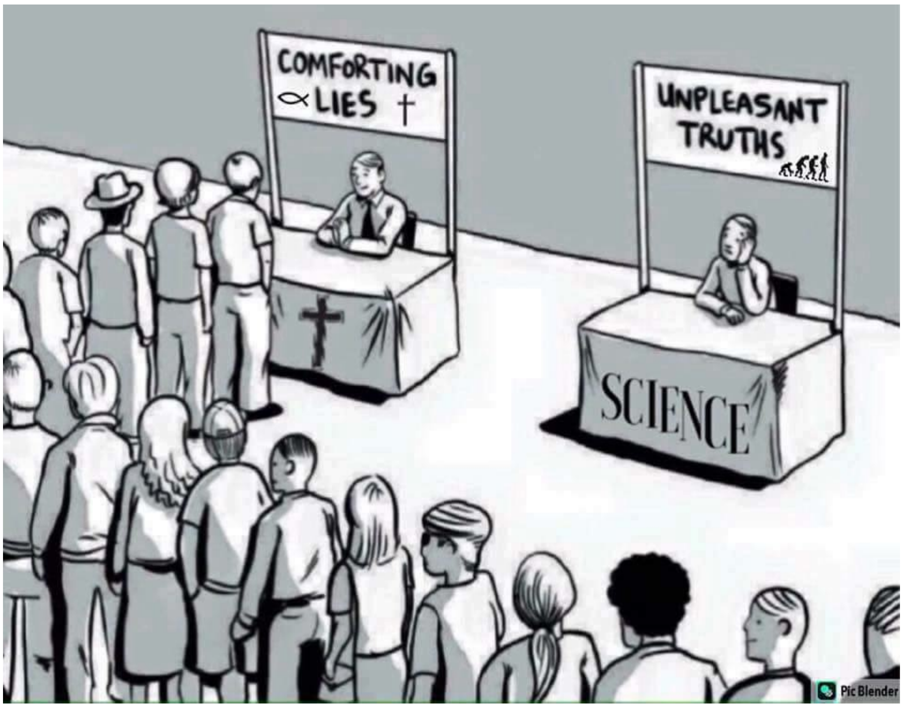
Scientists can also learn to avoid certain pitfalls. I spoke with Gretchen Goldman, research director of the Union of Concerned Scientists' Center for Science and Democracy, which offers communication and advocacy workshops. A counter-intuitive lesson she's learned is that refuting stories that deny climate change by addressing each claim and explaining why it's wrong is not that productive. In fact, it could be counter-productive: "If you repeat the myth, that's the part people remember even if you immediately debunk it", she says. A better approach, she suggests, is to reframe the issue. Don't just keep explaining why climate change is real, explain how climate change will hurt public health or the local economy. Communication that appeals to values, not just intellect, research shows, can be far more effective.

[...] But the obstacles faced by science communicators are not epistemological but cultural. The skills required are not those of a university lecturer but a rhetorician.

So it's an admirable goal to communicate about science, but almost certainly destined to fail. This is because the way most scientists think about science communication - that just explaining the real science better will help - is quite wrong. It's so wrong that it may have the opposite effect of what they're trying to achieve. [...]»

> ❝ *Silence is sometimes the best answer to the fools.* ❞

quote
4.5:119.#30



> ❝ *As a scientist (and atheist) you will often be hated by all those who believe in fairy tales and think that their opinions, anecdotes, circular logic and scientific illiteracy are worth it, but those who stands firm to the Scientific Method and to the precautionary principle will be saved and will help to save the haters. Comforting lies have always and are still taking the elevator and the Scientific Method takes the stairs, the lies will come first but one day or another the Science will always catch up with its unpleasant evidence.* ❞

quote
4.5:119.#31

4.6. Is Science dogmatic?

We will here mainly repeat things that we have already mentioned earlier above. However as some scientifically illiterate people still think in this beginning of the 121st century (holocene calendar) that YouTube videos containing some rhetorical monologue[61] or some books without proofs and without statistical data analysis constitute some sort of "evidence" it is necessary maybe to come back on a few topics but with a different perspective[62]!

For Science, if something exists with evidence beyond reasonable doubt (BRD), at its actual state of knowledge, then it means it can be measured! If it cannot be measured or is ill-defined, well, then science can't provide evidence that it doesn't exist (don't forget that the purpose of Science is to refute models and if it fails to do so a long time enough then a Model may take the status of "Theory"!). In a simplistic and slightly out of context metaphor, this is equivalent to say that for the blind (taking away all their other senses) the world doesn't exist with strong evidence because they cannot see it nor feel it. Some people then say that Science is materialist! However this doesn't mean at all that Science has failed as an investigation method, however it just means that Science knows it doesn't know everything otherwise it would stopped and that the scientific method must be corrected constantly according to the new available evidences.

DATA
over
DOGMA

Typically Science doesn't reject completely parapsychology powers or the existence of one of the thousand of deities created around the World by humans even if actually all experimental tests have rejected them with strong evidence (but not definitively!). The advocates of parapsychology or religions (or of some alternative medicines) may argue that Science can't prove nor disprove what it can't measure directly or indirectly. And they are very likely absolutely right! Science can only fail to reject with a given level of evidence if something exist or not at its actual level of knowledge. So if someone argue that flying unicorns exist without providing a protocol so that thousands of other people can check this fact in a reproducible way... then Science (scientists) humbly say us that: «*we don't have any evidence beyond reasonable doubt at our actual state of knowledge that unicorn exist or not!*»

So it's not Science that is dogmatic, nor the huge majority of the scientific community. But only some bad educated and biased scientists (nobody is perfect...).

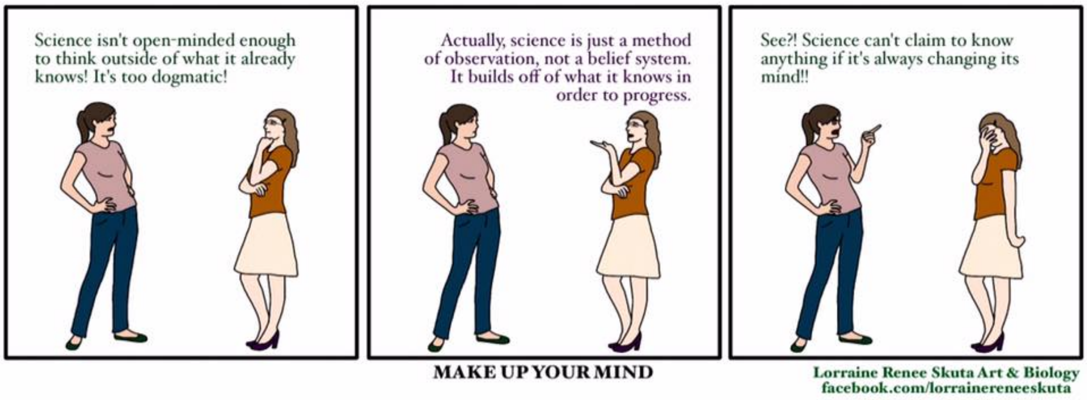
---

[61] As already said people should not trust monologues - whether on radio, television or any social network - because there are no experts to counter the possible wrong arguments or ill-defined concepts that may lead a part of the audience to wrong speculative interpretations! In addition, humans under the stress of knowing that they are recorded are naturally prone to vocabulary errors and that's without counting the more than 200 cognitive biases in the brain which sometimes lead to the erroneous simplification of complex thoughts... !

[62] And please don't forget that the purpose of Science is not the "Truth" but it's only a tool that explains quite well things that we see or feel following the best actual models. And also please don't forget that quoting a book, a famous scientist, a blog or a YouTube video is only at best an evidence of level 2 or 3!

Remark

We will also see later that Gödel's incompleteness theorem proves, from the non-conservativity argument, that there exist in certain mathematical theories (i.e. in certain systems of axioms) truth sentences which cannot be considered true without a notion of a more transcendental truth with respect to the basic underlying theory! Which is further proof that Science itself has demonstrated that it cannot in certain systems be a dogma!



Science isn't open-minded enough to think outside of what it already knows! It's too dogmatic!
Actually, science is just a method of observation, not a belief system. It builds off of what it knows in order to progress.
See?! Science can't claim to know anything if it's always changing its mind!!
MAKE UP YOUR MIND
Lorraine Renee Skuta Art & Biology
facebook.com/lorrainereneeskuta

Some humans don't like that scientists may not know everything about something, or that scientists do errors, and that science takes time and that even worst, these same people will maybe never have an answer to their main questions before their death. But that's how Science works actually!!! If anyone finds a more reliable and fast way to investigate the Universe and its phenomena than the actual state of the Scientific Method, then the majority of the scientific community - especially the academic part - is waiting to check it and if it works indeed better to adopt it!

> ❞ *Extraordinary claims require extraordinary evidence.* ❞
>
> Carl Sagan

quote 4.6:121.#32

So some people may ask Science to be truly scientific, meaning, it should question itself regarding the certainty of their own postulates and instruments. But as we already said many times in the previous sections above, this is what researchers do in their daily work!!! They try to find new evidence to reject actual theories, models, methods, postulates or bad instruments... otherwise Science would stop and scientists would lost their job. However the process is slow and takes days, weeks, months, years, decades, centuries and sometimes even millenniums.

Remark

Some people point out that the version of the Universe scientists currently have is only what their instruments, and especially their imagination allows them to understand. And they are right! We - all professional academic researchers - know that fact since centuries in Science and that's why every day we try to push the boundaries of knowledge (hence also of imagination) and to develop new instruments and methods to measure things that were not even known a few decades before! Keep in mind this is what we are paid for! If there is nothing new to discover we will all lost our jobs!

So yes in its current state, Science cannot account very well for consciousness phenomena, synchronicity, or even near death experiences or spontaneous epiphanies, etc. (even if tools like fMRI and EEG help to observe correlations with electric signals). But well educated professionals scientists won't claim they do or don't exist because we don't have yet any experimental reproducible evidence to support any of these positions! Scientists are just waiting for those who claim that such things exist - and even run quite good business with it - to provide us reproducible experimental evidence. Sadly so far all the people who made such claim and run business with them have failed to provide any evidence or were just simply debunked and that's all.

Anyone should ask himself why evangelist pastors or any kind of miraculous healer (...) don't practice their art in the scientific controlled environment of Hospitals rather that in their church (in front of a public in the huge majority biased, uneducated and scientifically illiterate) or with a small group of unknown and suspicious people behind a camera.......

People like Rupert Sheldrake, a PhD holder (from Cambridge) in biochemistry and retired researcher in the field of parapsychology who proposed the concept of morphic resonance... and also author of numerous rewarding books...... explores ten dogmas of Science that should be reconsidered according to his personal and subjective opinion...

Let us present below these ten dogmas and... we will comment them as Dr. Sheldrake doesn't have a PhD in Physics, nor in Cosmology but has a good sense of rhetoric especially when he does a monologue in front a public of neophytes (the reader and Dr. Sheldrake will be able to find the mathematical proof of our answers in the $9,000$ pages of this textbook if they are curious - as at the opposite of Dr. Sheldrake we like proofs and experimental evidence more than rhetorical monologue...):

1. “Nature is mechanic: all the creatures and systems of nature are robots made to follow a given genetic program.”

   ▷ Our comment: We are not sure of how the word "Mechanics" is defined in this sentence (the basics of a debate is to agree on the meaning of words...) but obviously a biological system cannot be compared to a mechanical one (mechanical system doesn't evolve). However as we will prove it in this textbook Nature is Information based at all levels, Probabilistic based at the microscope level, and behaves Statistically and Mechanically at macroscopic level. So as most of the time in Science..., it's not as easy as it seems to be (it seems that Dr. Sheldrake has a binary vision of the World and of the Universe that is quite surprising given his supposed level of education).

2. “Matter is unconscious: Plants, stars, animals and elements are material things that are and cannot have a consciousness of themselves.”

   ▷ Our comment: First we should ask how is "consciousness" defined by Dr. Sheldrake. Secondly, who asserted that in the scientific community? Is there a written scientific consensus on this subject or it comes out from the imagination of Dr. Sheldrake?

3. “The laws of nature are fixed: At the moment of the Big Bang (i.e. starting point of the expansion of our universe) all the necessary constants until the end of time were established. The habits of nature do not evolve.”

   ▷ Our comment: What scientific consensus stated that? That’s very likely wrong as actually we have a few mathematical-physics models that proves that the constants of the Universe may have changed and also experimental evidence that maybe the laws of Nature may have changed. But one thing is almost sure: there is no scientific consensus yet on that topic!

4. “The amount of nature and energy in the Universe is always the same.”

   ▷ Our comment: The scientific community has strong evidence beyond reasonable doubt of that statement for the observable Universe. However the dynamic of the Universe disprove energy conservation at large scales (this is derived from Noether theorems!). Notice that we have however no evidence yet of this statement of energy conservation for the whole Universe (the observable and not observable one).

5. “Nature has no purpose: there is no design in nature in terms of intention and the process of evolution is mechanic.”

   ▷ Our comment: We have strong evidence beyond reasonable doubt indeed that there is no design as the existing design are flawed in many ways. And the process of evolution as proven mathematically in this textbook and experimentally (beyond any reasonable doubt) in laboratories is not mechanical but stochastic.

6. “Biologic Heritage: The plans to produce a living being are composed within the physical matter lodged in their genes.”

   ▷ Our comment: That’s not completely correct. Experimental observations provide us that some basics of the plans are random and influenced by external and internal modifications. Again Dr. Sheldrake gives a binary view of a phenomenon which is far more complex. But this is something we know as typical of scientific illiterate people: they reduce something complex to something simple because they can’t grasp the complexity of the World and of the Universe.

7. “Memory is kept in the brain as material prints: memory is made of proteins and nerve endings organized as a drawer within itself.”

   ▷ Our comment: If it was the case we wouldn’t forget things... That’s because the brain is far more complex and involves probabilities, Bayesian and stochastic process that we know why the human brain forgets things and has sometimes building issues...

8. “Mind is in the head: The mind has a physical connection with the head and the brain, relegating intellectual subordination on the rest of the body.”

   ▷ Our comment: What is the "Mind" for Dr. Sheldrake? As far as we know there is no scientific consensus about its definition. Furthermore is Mind what we observe in MNR scanners?

9. “Phenomena like telepathy are impossible: thoughts have no effect in the world because of number 8 on the list (the mind is in the head).”

   ▷ Our comment: What scientific consensus or community stated that? Actually Science has no evidence that telepathy works or exist, yes (!) - but no well educated scientist would say it is "impossible" (by the way any well educated scientist know that is better to avoid using the word "impossible" about an unknown future or unmeasurable phenomena).

10. “Only mechanical medicine works: It is merely by chance or placebo effects that traditional healing practices or natural remedies have any effect on people’s health.”

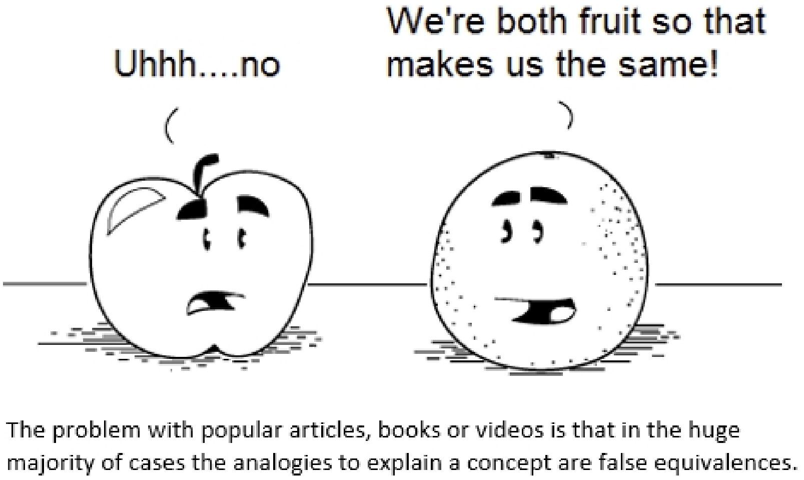
    ▷ Our comment: Again... what scientific consensus or community stated that? That’s not accurate. Maybe scientists agree on the fact that actually not other method than the Scientific Medicine has provided better odds ratio than other medicines. But if one day some people provide robust evidence that traditional healing practices or natural remedies work, then almost surely they will be promoted by the scientific academic community.

If this is the best support Dr. Sheldrake has for his position, then this means that there is no support. It is entirely based on gish gallop and speculation, pointing to common misconceptions and popular opinions rather than evidence and examples of "dogma" in science.

We can understand why someone reading or listening this kind of gish gallop may think that there is some basis of evidence. Gish gallop means making loads of claims without evidence, leaving the opposition the large job of checking each and every claim. Even so, when someone claims the "establishment" is dogmatic, immoral or whatsoever, we may sincerely hope that any reader will critically assess that person claims.

quote 4.6:124.#33

> *A religious belief without dogma is not possible and science is not compatible with any dogma. So science can only be incompatible with religious beliefs.*
>
> ?



Uhhh....no
We're both fruit so that makes us the same!

The problem with popular articles, books or videos is that in the huge majority of cases the analogies to explain a concept are false equivalences.

5.1. Proof Theory

We have chosen to begin the study of Applied Mathematics by the theory that seems to us the most fundamental and important in the field of pure and exact sciences: Proof Theory and its underlying formal systems! The proof theory and theory of propositional calculus (logic) have five main objectives through this book:

1. Teach to the reader how to reason and demonstrate (prove), and this independently of the specialization field.
2. Show that the process of a demonstration (proof) is independent of the language used.
3. Prepare the reader to the Logic Theory (see section Logic Systems page 7104).
4. Prepare the path to Gödel's incompleteness theorem (main goal of this section!).
5. Prepare the reader to the Automata Theory (see section Automata Theory page 7181).

The two Gödel theorems are probably the most exciting points of Proof Theory because if we define religion as a system of thought that contains unprovable statements, then it contains elements of faith, and Gödel tells us that mathematics is not only a religion, but that it is the only religion that can prove itself that it is one!

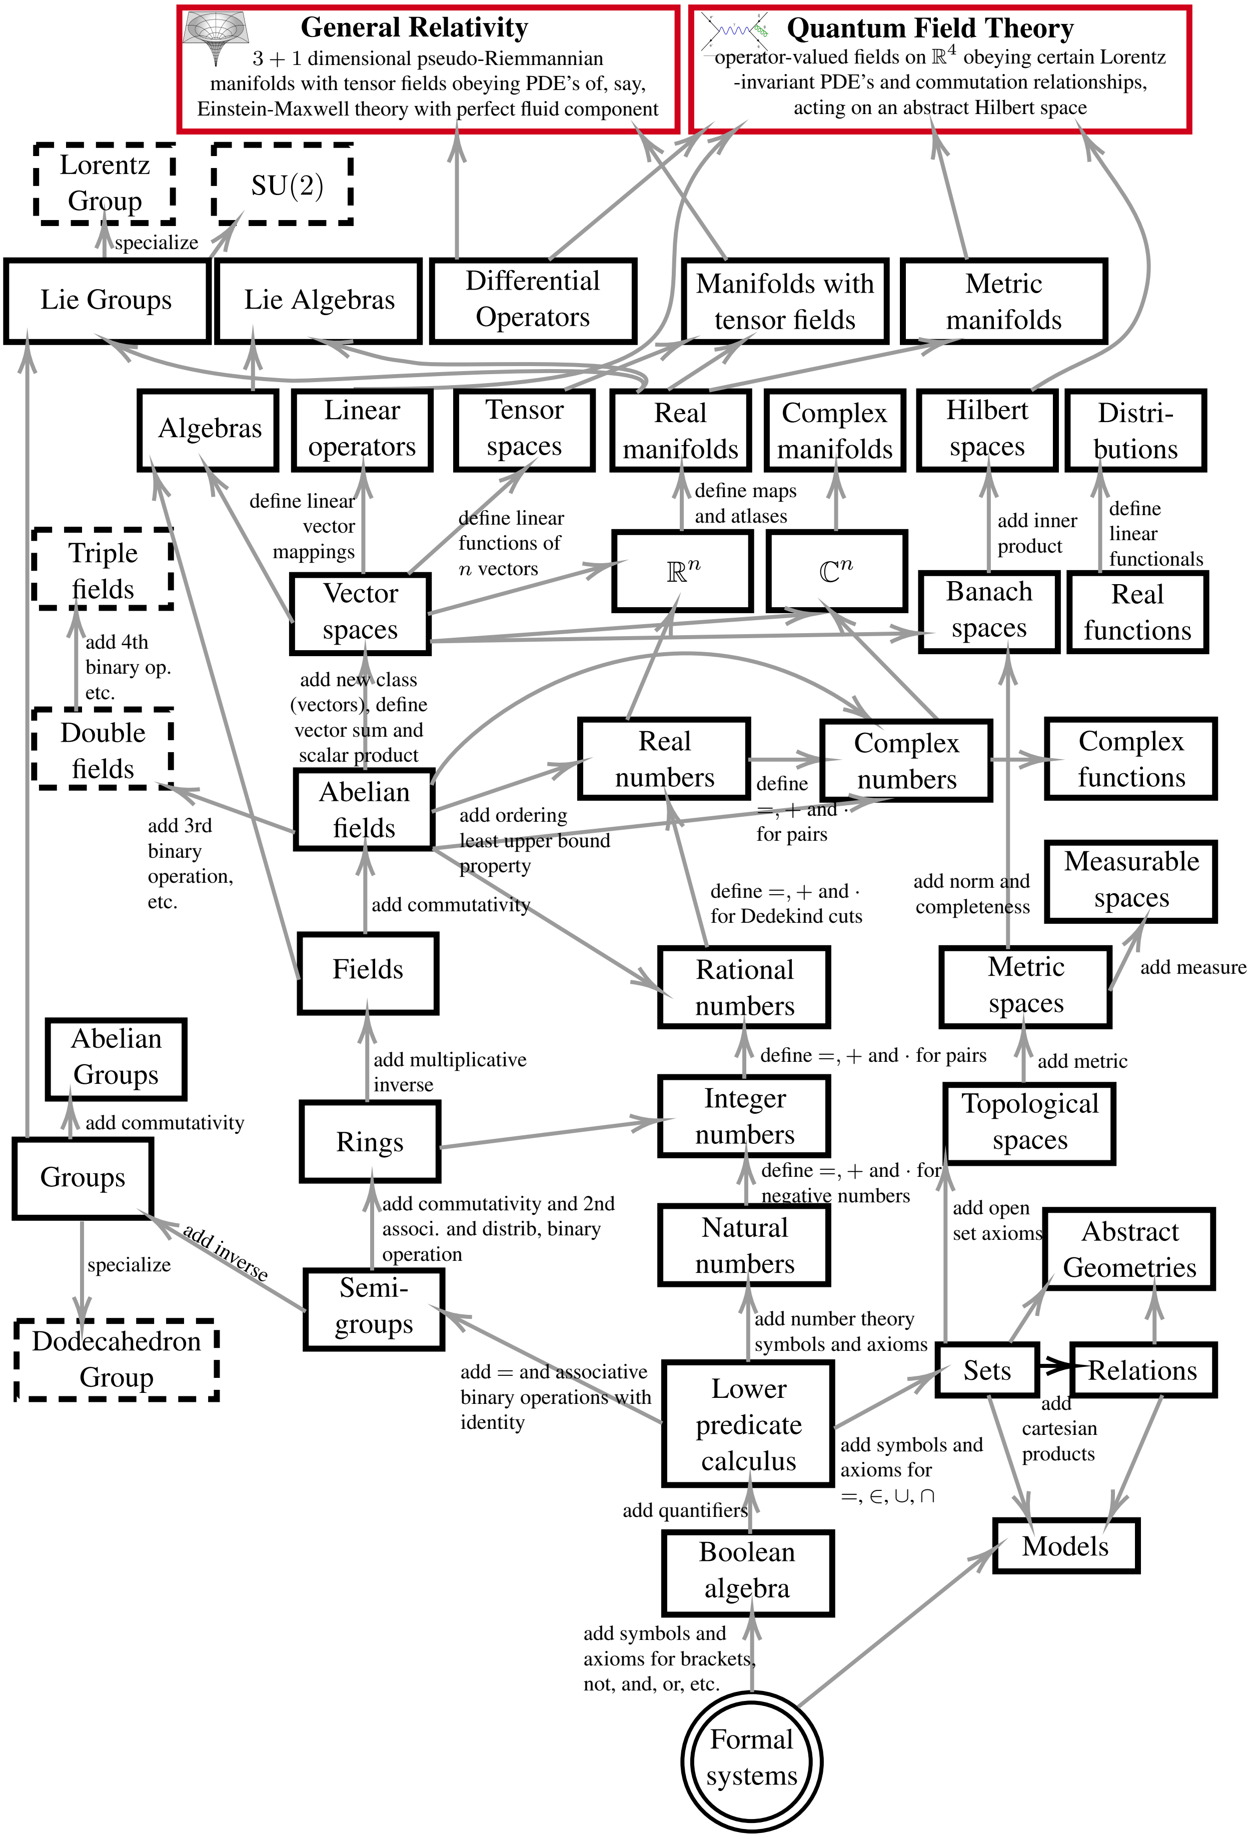
Gödel's incompleteness theorem state that in any axiomatic system there are some statements that cannot be determined to be true or false (but some are!). The incompleteness theorem seems like something horrible, and for mathematics, it is! However, it does not apply to physics (or any other experimental science), because physics does not rely on logical proof in axiomatic systems, it relies on empirical evidence!

Remarks

R1. It is (very) strongly advised to read this section in parallel with those on Automata Theory (page 7181) and Logical Systems (page 7104), including Boolean Algebra (page 7105), available in Theoretical Computing (page 6267) chapter of this book.

R2. We must approach Proof Theory as a sympathetic curiosity but which basically brings nothing much except working/reasoning methods. Moreover, its purpose is not to show that everything is demonstrable but that any proof can be done on a common language starting from a finite number of rules.

As illustrated in the figure below, taken from the book [531], formal system are at the root of the two main targets of the present book that are General Relativity and Quantum Field Theory:



General Relativity
3 + 1 dimensional pseudo-Riemmannian manifolds with tensor fields obeying PDE's of, say, Einstein-Maxwell theory with perfect fluid component
Quantum Field Theory
operator-valued fields on $\mathbb{R}^4$ obeying certain Lorentz -invariant PDE's and commutation relationships, acting on an abstract Hilbert space
Lorentz Group
SU(2)
specialize
Lie Groups
Lie Algebras
Differential Operators
Manifolds with tensor fields
Metric manifolds
Algebras
Linear operators
Tensor spaces
Real manifolds
Complex manifolds
Hilbert spaces
Distri-butions
define linear vector mappings
define linear functions of n vectors
define maps and atlases
add inner product
define linear functionals
Triple fields
Vector spaces
$\mathbb{R}^n$
$\mathbb{C}^n$
Banach spaces
Real functions
add 4th binary op. etc.
add new class (vectors), define vector sum and scalar product
Double fields
Abelian fields
Real numbers
Complex numbers
Complex functions
define =, + and · for pairs
add 3rd binary operation, etc.
add ordering least upper bound property
add commutativity
define =, + and · for Dedekind cuts
add norm and completeness
Measurable spaces
add measure
Fields
Rational numbers
Metric spaces
Abelian Groups
add commutativity
add multiplicative inverse
define =, + and · for pairs
add metric
Groups
Rings
Integer numbers
Topological spaces
define =, + and · for negative numbers
add open set axioms
specialize
add inverse
add commutativity and 2nd associ. and distrib, binary operation
Natural numbers
Abstract Geometries
Semi-groups
Dodecahedron Group
add number theory symbols and axioms
Sets
Relations
add = and associative binary operations with identity
Lower predicate calculus
add symbols and axioms for =, ∈, ∪, ∩
add cartesian products
add quantifiers
Models
Boolean algebra
add symbols and axioms for brackets, not, and, or, etc.
Formal systems

Figure 5.1: **Oversimplified relations between various important mathematical structures for physics (author: Max Tegmark)**

Often when a student arrives in a graduate class he learned how to calculate or use algorithms but almost only a little or even not at all to reason (for the evolutionary origin of reasoning see [387]). For all the reasoning the visual media is a powerful tool (a picture is worth a thousand words) and people who do not see that in tracing a given curve or straight line the solution appears or who do not see in space are really penalized.

During high school we already manipulate unknown objects but especially to make calculations and when we reason about objects represented by letters, we can replace them visually by a real number, a vector, etc. At a given level we ask people to reason on more abstract structures and therefore to work on unknown objects which are elements of a set itself unknown, for example elements of any group (see section Set Theory page 421). This visual support thus doesn't exist anymore.

We ask so often to students to reason, to demonstrate the properties, but almost no one has ever taught them to reason properly, writing proofs, control proofs. If we ask a graduate student what is a proof, it most likely he will have some difficulty to answer. He can say that it is a text in which there are keywords like "therefore", "because", "if", "if and only if", "take a x such that", "assume", "lemma", "theorem", "let us look for a contradiction", etc. But he will probably be unable to provide the grammar of these texts nor their basics, and besides, its teachers, if they have not taken a course in Proof Theory, would probably be unable too.

To understand this situation, remember that to speak a child does not need to know the grammar. He imitates his surroundings and it works very well: most of time a six year old child know to use complicated sentences without ever having done grammar. Most teachers also do not know the grammar of reasoning but, for them, the imitation process has work well and thus they reason correctly. The experience of the majority of university teachers shows that this process of imitation works well for very good students, and then it is enough, but it works much less, if not at all, for many others.

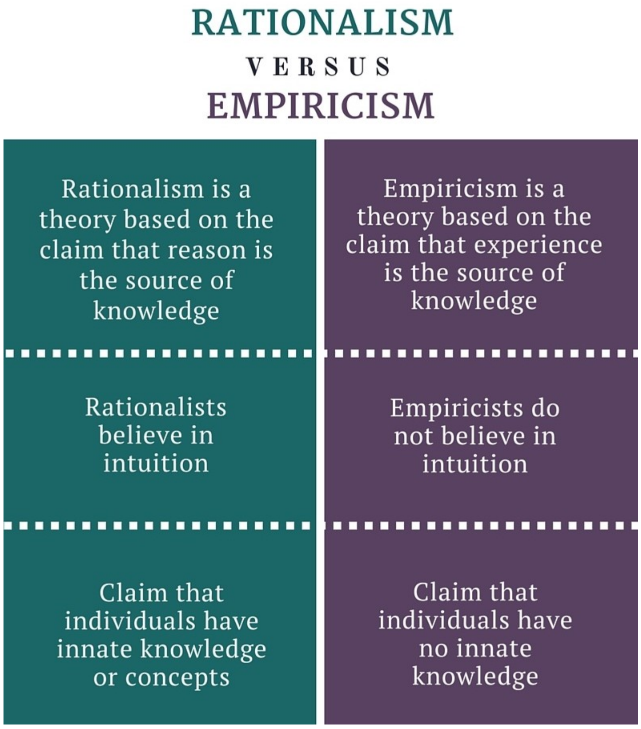
As the complexity level is low (especially during an "equational" type reasoning), grammar is almost useless but when the level increase or when we do not understand why something is wrong, it becomes necessary to do some grammar to progress. Teachers and students are familiar with the following situation: in a school assignment the corrector barred whole page of a large red line and write "false" in the margin. When the student asks what is wrong, the corrector can only say things like "this has no relation with the requested proof", "nothing is right", ..., which help obviously not the student to understand. This is partly because the text written by the student uses the appropriate words but in a more or less random way and can not give meaning to the assembly of these words. In addition, the teacher does not have the tools to explain what is wrong. We must therefore give them to him!

These tools exist but are fairly recent. The proof theory is a branch of mathematical logic whose origin is the crisis of the foundations: there was a doubt about what we had the "right" to do in a mathematical reasoning (see the "foundations crisis" further below). Paradoxes appeared, and it was then necessary to clarify the rules of proof and to verify that these rules are not contradictory. This theory appeared in the early 120th century (holocene calendar), which is very new since most of the mathematics taught in the first half of the university is known since the 116th-117th century (holocene calendar).

5.1.1 Foundations Crisis

For the Greeks philosophers geometry was considered the highest form of knowledge, a powerful key to the metaphysical mysteries of the universe. It was rather a mystical belief and the link between mysticism and religion was made explicit in cults like those of the Pythagoreans.

No culture has since challenged a man for having discovered a geometrical theorem! Later, mathematics was regarded as the model of a priori knowledge in the Aristotelian tradition of rationalism.



RATIONALISM
VERSUS
EMPIRICISM

Rationalism is a theory based on the claim that reason is the source of knowledge	Empiricism is a theory based on the claim that experience is the source of knowledge
Rationalists believe in intuition	Empiricists do not believe in intuition
Claim that individuals have innate knowledge or concepts	Claim that individuals have no innate knowledge

The astonishment of the Greeks philosophers for mathematics has not left us, we find it in the traditional metaphor of mathematics as "Queen of Science". It was strengthened by the spectacular success of mathematical models in science, success that the Greeks (even ignoring the simple algebra) had not anticipated. Since the discovery by Isaac Newton's of integral calculus and the inverse square law of gravity in the late 11600s (holocene calendar) the phenomenal sciences and higher mathematics remained in close symbiosis - to the point that a predictive mathematical formalism was became the hallmark of a "hard science".

After Newton, during the next two centuries, science aspired to that kind of rigour and purity that seemed inherent in mathematics. The metaphysical question seemed simple: mathematics seemed to have a perfect a priori knowledge, and among all sciences, those that were able to mathematize most perfectly were the most effective for predicting phenomena. The perfect knowledge therefore, was in a mathematical formalism that, once reached by science and embracing all aspects of reality, could found a posteriori empirical knowledge on an a priori rational logic. It was in this spirit that Marie Jean-Antoine Nicolas de Caritat, Marquis de Condorcet (French philosopher and mathematician), undertook to imagine describing the entire Universe as a set of partial differential equations being solved one after the other.

The first break in this inspiring picture appeared in the second half of the 119th century (holocene calendar), when Riemann and Lobachevsky separately proved that Euclid's parallel axiom (see the definition page 100) could be replaced by other geometries that produced "consistent" (we will come back more on this word further below). Riemannian geometry was modelled on a sphere, these of Lobatschewsky, on rotation of a hyperboloid.

The impact of this discovery was later obscured by great upheaval, but at the time it made a thunderclap in the intellectual world. The existence of mutually inconsistent axiomatic systems, each of which could be a model for the phenomenal Universe, relied entirely into question the relation between mathematics and theoretical physics.

When we knew only Euclid, there was only one possible geometry. One could believe that the Euclid's postulates (see section Euclidean Geometry page 2563) were a kind of knowledge a priori perfect on the geometry in the phenomenal world. But suddenly we had three geometries, embarrassing for metaphysical subtleties.

Why would we choose between the axioms of plane geometry, spherical and hyperbolic geometry as real descriptions? Because all three are consistent, we can not choose any a priori as a foundation - the choice must be empirical, based on their predictive power in a given situation.

Of course, the theoretical physicists have long been accustomed to choose a formalism to study a scientific problem. But it was already accepted widely, if not unconsciously, that the need to do so was based on human ignorance, and with logic or good enough mathematics, one could infer the right choice from principles first, and produce a priori descriptions of reality that had to be confirmed afterwards by empirical verification.

However, Euclidean geometry, seen for hundreds of years as the model of axiomatic perfection of mathematics, had been dethroned. If we could not know a priori something as basic as the geometry in space, what hope was there for a pure rational theory that would encompass all of nature? Psychologically, Riemann and Lobachevsky had struck at the heart the mathematical enterprise as it had been designed before.

Moreover, Riemann and Lobachevsky have pushed the nature of mathematical intuition into question. It was easy to believe implicitly that mathematical intuition was a form of perception - a way to glimpse the Platonic world behind reality. But with two other geometries pushing the Euclid one in it's limit, no one could never be sure to know what the world really looks like.

Mathematicians responded to this dual problem with excessive rigour, trying to apply the axiomatic method in all mathematics. In the pre-axiomatic period, the proofs were often based on commonly accepted intuitions of the "reality" of mathematics, which could not automatically be regarded as valid.

The new way of thinking about mathematics led to a series of spectacular success. Yet this had also a price. The axiomatic method made the connection between mathematics and the phenomenal reality increasingly close. Meanwhile, discoveries suggested that mathematical axioms that appeared to be consistent with phenomenal experience could lead to dizzying contradictions with this experience.

Most mathematicians quickly became "formalist" arguing that pure mathematics could only be regarded as a kind of elaborate philosophy game that was played with symbols on paper (that's the theory that is behind the mathematical prophetic qualification "zero content system" by Robert Heinlein). The "Platonic" belief in the reality of mathematical objects, in the old-fashioned way, seemed good 20th the trash, despite the fact that mathematicians still feel like platonicians during the process of discovery of mathematics.

Philosophically, then, the axiomatic method led most mathematicians to abandon previous beliefs in the metaphysical specificity of mathematics. It also produced the contemporary rupture between pure and Applied Mathematics. Most of the great mathematicians of the early modern period - Newton, Leibniz, Fourier, Gauss and others - also occupied phenomenal science. The axiomatic method had hatched the modern idea of the pure mathematician as a great aesthete, heedless of physics. Ironically, formalism gave the pure mathematicians a bad addiction to the Platonic attitude. The researchers in Applied Mathematics ceased to meet physicists and learned to put themselves in their behind.

This takes us to the early 120th century (holocene calendar). For the beleaguered minority of Platonists, the worst was yet to come. Cantor, Frege, Russell and Whitehead showed that all pure mathematics could be built on the simple foundation of the Set Theory axiomatic. This suited well the formalists: the mathematics were reunifying, at least in principle, from a small set of rules detached of a big one. Platonicians also were satisfied, if a great structure appeared, consistent keystone for the whole mathematics, the metaphysical specificity of mathematics could still be saved.

In a negative way, though, a Platonist had the last word. Kurt Gödel put his grain of sand in the program of axiomatization formalism when he proved that any sufficiently powerful axiom system to include integers numbers had to be either inconsistent (contain contradictions) or incomplete (too weak to decide the rightness or the falsity of some statements of the system). And that's more or less where things stand today. Mathematicians know that many attempts to advance mathematics as a priori knowledge of the Universe must face numerous paradoxes and unable to decide which axiom system describes the real mathematics. They have been reduced to hope that standards axiomatizations are not inconsistent but just incomplete, and wondering anxiously what contradictions or unprovable theorems are waiting to be discovered elsewhere.

However, on the front of empiricism, mathematics was always a spectacular success as a theoretical construction tool. The great success of physics in the 120th century (General Relativity and Quantum physics) pushed so far out of the realm of physical intuition, they could only be understood by meditating deeply on their mathematical formalism, and extending their logical conclusions, even when those findings seemed wildly bizarre. What irony! Just as the mathematical perception were to appear always less reliable in pure mathematics, it became more and more indispensable in phenomenal science.

In contrast to this background, the applicability of mathematics to phenomenal science poses a more difficult problem than at first appears. The relation between the mathematical models and prediction of phenomena is complex, not only in practice but also in principle. Even more complex, as we now know, there are ways to axiomatize mathematics that mutually exclude themselves!

But why is there only one good choice of mathematical model? That is, why is there a mathematical formalism, for example for quantum physics, so productive that it predicts the discovery of new observable particles?

To answer this question we will can observe that, as well, works as a kind of definition. For many phenomenal systems, such exact predictive formalism has not been found, and none seem plausible. You can easily find such examples: climate or the behaviour of a superior economy to that of a town - systems so chaotically interdependent that exact prediction is actually impossible (not only in practice but in principle).

> *One should study mathematics simply because it helps to arrange one's ideas!*

Math helps us describe patterns, measure the world, model reality, and solve problems.

5.1.2 Paradoxes

Since ancient times, some logicians had noticed the presence of many paradoxes within rationality. In fact, we can say that despite their number, these paradoxes are merely illustrations of a few paradoxical structures. Let us look to for general culture to the most famous which constitute the class of "undecidable propositions".

Let us see one of the most well known example: The paradox of the class of classes (Russell)!

✍**Example:**

There are two types of classes: those that contain themselves (or reflexive classes: the class of non-empty sets, the class of classes, ...) and those who do not contains themselves (or non-reflexives classes: the class of work to be returned, the class of blood oranges, ...). The question is the following: is the class of non-reflexives classes itself reflexive or non-reflexive? If it is reflexive, it contains itself and is thus in the class of non-reflexives classes that it represents, which is contradictory. If it is non-reflexive, it must be included in the class of non-reflexives classes and becomes ipso facto reflexive, we are facing again a contradiction.

This Russell's paradox is often known mainly under the two following variants:

- Does the set of all sets that do not contain themselves contain himself?

  The answer is: If "Yes", then "No" and if "No" then "Yes"...

  Remark

  A religious funny version of this paradox is the following: Can the Almighty (whatever the deity of one of the 45 monotheistic religions) create an entity more powerful than Him? No! Then he is not all-powerful. Yes, then he is not all-powerful.

- Those who do not shave themselves are shaved by the barber but not those who shave themselves. So who shaves the barber?

  The answer is: If the barber shave himself he enters in the category of people that shave themselves so he does not shave himself because he is the barber... But if he does not shave himself he enters in the category of people that are shaved by the barber... The answer is also undecidable...

The Universe is a reflexive class (it contains itself). Therefore the Russell paradox doesn't apply to it by construction!

Russell's paradox challenges the notion of a set as a collection defined by common ownership! In one shot it destroys the logic (undecidable proposition) and set theory... because the overall concept of all sets is an impossibility!!! The self-reference is the center of this logical problem!

Formally, Russell's paradox is stated and proved in just a few lines:

$$\boxed{\begin{gathered}S=\{x:x\notin x\}\\ S\in S\Longleftrightarrow S\notin S\end{gathered}} \tag{5.1.1}$$

This paradox also returns to the question whether a math question correctly formulated (logical) necessarily admits an answer? Said in another way: is any mathematical statement provable... and it is Gödel that many years after the statement of Russell's paradox proved mathematically that the answer is No !!!!!! In other words, there will always be questions unanswered because any system (living language or mathematical tool) based itself is necessarily incomplete! This is the famous impact of Gödel's incompleteness theorem that is technically written as following (and that we will have to prove):

$$\boxed{\exists P:\quad \neg\mathrm{Dem}(P)\wedge\neg\mathrm{Dem}(\neg P)} \tag{5.1.2}$$

that means that given a proposition P, whatever the set of axioms, there exist proposition that we will be never able to prove as true or false.

Let us see another application of the Russell's paradox:

✍**Example:**

In a library, there are two types of catalogues: Those who mention themselves and those who does not mention themselves. A librarian must draw up a catalogue of all catalogues that do not mention themselves. Having completed its work, our librarian asks whether or not to mention the catalogue that is precisely drafting. At this point, he is struck perplexity. If he does not mention this catalogue it will be a catalogue that is not mentioned and which should therefore be included in the list of catalogues that does not mention themselves. On the other hand, if he mentions the catalogue, this catalogue will become a catalogue that is mentioned and must therefore not be included in this catalogue, since it is the catalogue of catalogues which does not mention themselves.

A variations of the previous paradox is the well-known liar paradox:

✍**Example:**

Let us provisionally define lying as the work of making a false proposition. The Cretan poet Epimenides said: "All Cretans are liars", this is the proposal P. How to decide the truthfulness of P? If P is true, as Epimenides is Cretan, P must be false. P must therefore be false to be true, which is contradictory.

As would have made understand the logician Ludwig Wittgenstein, these paradoxes ultimately show that mathematics is a pretty good tool to show the logic but not to talk about it. Give with mathematics an independent existence to this algebraic entities is madness and it is this that produces monsters like the set of all the sets... The logic is empty and can not tell the reality, it restrict to be just a picture of it.

The reader may be always careful to distinguish paradoxes, sophisms and ill-defined (ill-specified) problems or popular myths (provided without evidence for that latter obviously...). That's one of the biggest source of misunderstanding in many debates.

✍**Example:**

If you choose an answer to this question at random, what is the chance you will be correct?

A) 25%

B) 50%

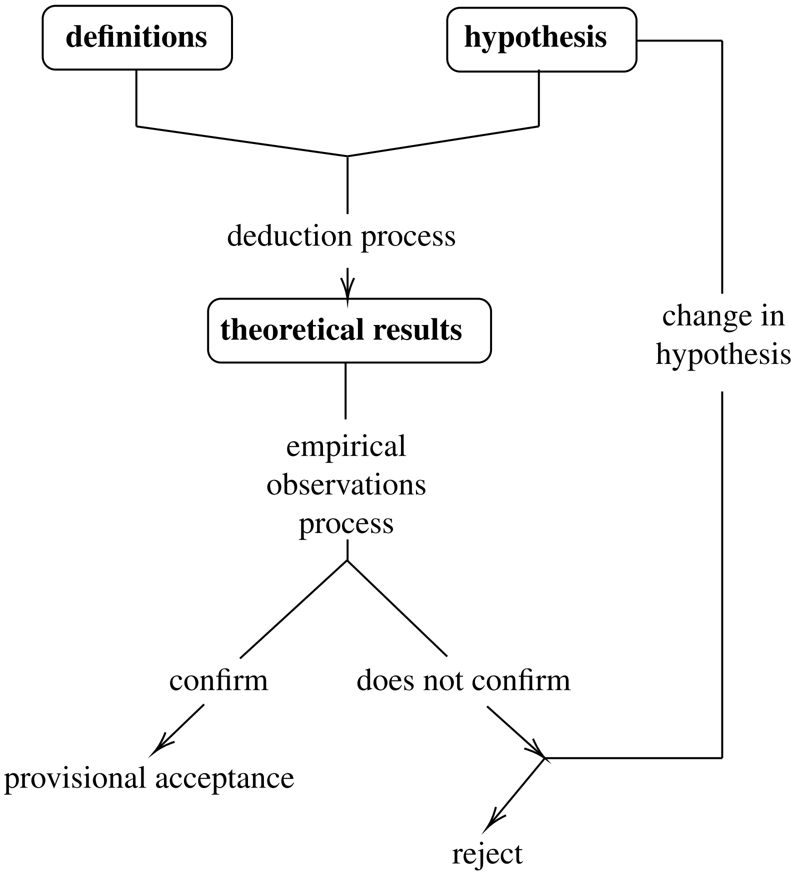
C) 60%

D) 25%

This is an ill-defined question. There are no solution and lead therefore to a paradox.

5.1.2.1 Hypothetical-Deductive Reasoning

The hypothetical-deductive reasoning is, we know (see the Introduction of the book), the ability of the learner to deduce conclusions from pure hypotheses and not only of a real observation. It is a thought process that seeks to identify a causal explanation of any phenomenon (we will come back on this during our first steps in physics). The learner who uses this type of reasoning begins with a hypothesis and then tries to prove or disprove his hypothesis following the block diagram below:



definitions
hypothesis
deduction process
theoretical results
change in hypothesis
empirical observations process
confirm
does not confirm
provisional acceptance
reject

Figure 5.2: **Hypothetical-Deductive Reasoning block diagram**

The deductive procedure is to hold as true, provisionally, this first proposal that we name, in logic a "predicate" (see further below for more details) and to draw all the consequences logically necessary, that is to say to look for its implications.

✍**Example:**

Consider the proposition (antecedent) P: "X is a man", it implies the following proposition (consequent) Q: "X is mortal".

The expression $P \Rightarrow Q$ (if it is a human it is necessarily mortal) is a predicative implication (hence the term "predicate"). There is no case in this example where we can state P without Q. This example is that of strict implication, as we find in the "syllogism" (logical reasoning figure).

In logic, a "syllogism" is a logical reasoning relating at least three propositions: two (named commonly "minor premise", "major premise") or more of them, named "premises", lead to a "conclusion".

A very well-known example of syllogism is: «*All men are mortal, but Socrates is a man; therefore Socrates is mortal*»: the two premises (named "major premise" and "minor premise") are propositions given and assumed to be true, the syllogism makes it possible to establish the formal validity of the conclusion, which is necessarily true if the premises are true.

Remark

Experts have shown that the hypothetical-deductive reasoning develops gradually by children from six to seven years old and that this kind of reasoning is used systematically starting with a strict propositional function until the age of eleven-twelve.

5.1.3 Propositional Calculus

First let us define what is "logic" in its contemporary sense otherwise using old definition we can prove that unicorns exist (as we will prove it further below!).

Definition (#5.1.7): "Logic" is the scientific study, especially formal, of the standards of truth (i.e. of correct reasoning) in a given axiomatic framework. "Formal logic", that is a subfamily, is the science of deductively valid inferences or logical truths. It studies how conclusions follow from premises due to the structure of arguments alone, independent of their topic and content. "Informal logic", that is another subfamily, is associated with informal fallacies, critical thinking, and argumentation theory.

The "propositional calculus" (or "propositional logic") is an absolutely indispensable preliminary to tackle a background in science, philosophy, law, politics, economics, etc. This type of calculation allows for decisions or testing procedures. These help to determine when a logical expression (proposition) is true and especially if it is always true.

Definitions (#5.1.8):

D1. An expression that is always true whatever the content language of the variables that compose it is named a "valid expression", a "tautology" or a "law of propositional logic".

In other words a tautology is a statement that is always true because it includes all logical possibilities.

D2. An expression that is always false is named a "contradiction" or "antilogy".

D3. An expression that is sometimes true, sometimes false is named a "contingent expression" (this is often linked to the analogy that something can exist but does not necessarily have to exist.).

D4. We name "assertion" an expression that we can say unambiguously whether it is true or false.

D5. The "object language" is the language used to write logical expressions.

D6. The "meta-language" is the language used to talk about the object language in everyday language.

Remarks

R1. There are expressions that are actually not assertions. For example, the statement "this statement is false" is a paradox that can be neither true nor false.

R2. Consider a logical expression A. If it is a tautology, we denote it by $\models A$ and by $A \models$ or $\not\models A$ if it is a contradiction.

R3. In mathematics we can try to prove in a general way that an assertion is true, but not that it is false (if this is the case we give just one example).

5.1.3.1 Propositions (premises)

Definition (#5.1.9): In logic, a "proposition" is a statement that has meaning. That means we can say unambiguously whether this statement is true (T) or false (F). This is what we name the "law of excluded middle".

✍**Examples:**

E1. "I lie" is not a proposition (premise). If we assume that this statement is true, it is an affirmation of his own disability, so we should conclude that it is false. But if we assume that it is false, then the author of this statement does not lie, so he told the truth, thus the proposal would be true...

E2. Another funny example is:

- Everything has a creator
- God is that creator
- God does not have creator

It's a solution that fails since it violates its own premise...

Definition (#5.1.10): A proposition in binary logic (where the proposals are either true or false) is therefore never true and false at the same time. This is what we name the "principle of non-contradiction".

Thus, a property on the set of propositions E is an application P from E to the set of "truth values True, False" $\{T,F\}$:

$$P : E \mapsto \{T,F\} \tag{5.1.3}$$

We speak about "associated subset" , when the proposition only generates a portion E' of E and vice versa.

✍**Example:**

In $E = \mathbb{N}$, if $P(x)$ states "x is even", then $P = \{0,2,4,\ldots,2k,\ldots\}$ which is indeed only an associated subset of E but of same cardinal (see section Set Theory page 388).

Definition (#5.1.11): Let P be a property of the set E. A property Q on E is a "negation" of P if and only if, for any $x \in E$:

- $Q(x)$ is F (false) if $P(x)$ is T (true)
- $Q(x)$ is T (true) if $P(x)$ is F (false)

We can gather these conditions in a table named "truth table":

P	Q
T	F
F	T

Table 5.1: **Truth table of values**

Table that we can also find or also write in the most explicit following form:

P	Q
True	False
False	True

Table 5.2: **Truth table of explicit values**

or in binary form:

P	Q
1	0
0	1

Table 5.3: **Truth table of binary values**

In other words, P and Q always have opposite truth values. We denote this kind of statement "Q is a negation of P":

$$Q \Leftrightarrow \neg P \tag{5.1.4}$$

where the symbol $\neg$ is the "negation connector".

Remark

The expressions must be well-formed expressions (often abbreviated "WFE"). By definition, any variable is a well-formed expression, thus $\neg P$ is a well-formed expression. If P, Q are well-formed formulas, then $P \Rightarrow Q$ is a well-formed expression (the expression "I am lying" is not well-formed because it contradicts itself).

5.1.3.2 Connectors

There are other types of logical connectors:

Definition (#5.1.12): Let P and Q two properties set defined on the same set E. $P \vee Q$ (read "P `OR` Q") is a statement (property) on E defined by:

- $P \vee Q$ is true if at least P or Q are true
- $P \vee Q$ is false otherwise

We can write the truth table of the "`OR` connector" or "disjunction connector" $\vee$:

P	Q	$P \vee Q$
T	T	T
T	F	T
F	T	T
F	F	F

Table 5.4: `OR` inclusive truth table

The reader must me careful not to confound the Exclusive `OR` that means "*either this or that, but not both*" with the Inclusive `OR` that means "*either this, or that, or both*". The truth table of that first one, denoted most of times with the symbol $\oplus$ (and very rarely denoted with the symbol $\veebar$), is obviously a bit different:

P	Q	$P \oplus Q$
T	T	F
T	F	T
F	T	T
F	F	F

Table 5.5: `OR` exclusive (XOR) truth table

Every natural number is either even or odd, but not both. So every natural number is even xor odd (that's short for exclusive or).

It should be easy to convince yourself that if the parts P, Q of E are respectively associated with the properties P, Q thus $P \cup Q$ (see section Set Theory page 383) is associated to $P \vee Q$:

$$\begin{aligned} P &\leftrightarrow P \\ Q &\leftrightarrow Q \\ P \vee Q &\leftrightarrow P \cup Q \end{aligned} \tag{5.1.5}$$

The connector $\vee$ is associative (no doubt about the fact that it is commutative!). For proof, just do a truth table where you can check that:

$$[P \vee (Q \vee R)] = [(P \vee Q) \vee R] \tag{5.1.6}$$

Definition (#5.1.13): There is also the "`AND` connector" or also named "conjunction connector" $\wedge$ for whatever are P, Q two properties defined on E, $P \wedge Q$ is a property defined on E by:

- $P \wedge Q$ is true if both properties P, Q are true (the famous syllogism: *All men are mortal, Socrates is a man, therefore Socrates is mortal* is a famous example).
- $P \wedge Q$ if false otherwise

We can write the truth table of the "`AND` connector" or "conjunction connector" $\vee$:

P	Q	$P \wedge Q$
T	T	T
T	F	F
F	T	F
F	F	F

Table 5.6: `AND` **truth table**

It should be also almost easy to convince yourself that if the parts P, Q of E are respectively associated with the properties P, Q thus $P \cap Q$ (see section Set Theory page 394) is associated to $P \wedge Q$:

$$\begin{gathered} P \leftrightarrow P \\ Q \leftrightarrow Q \\ P \wedge Q \leftrightarrow P \cap Q \end{gathered} \tag{5.1.7}$$

The connector $\wedge$ is associative (no doubt about the fact that it is commutative!). For proof, just do a truth table where you can check that:

$$[P \wedge (Q \wedge R)] = [(P \wedge Q) \wedge R] \tag{5.1.8}$$

The connectors $\vee, \wedge$ are distributive one on the other. Using a simple truth table, we can show that (ask me if you want a put the truth table):

$$[P \vee (Q \wedge R)] = [(P \vee Q) \wedge (P \vee R)] \tag{5.1.9}$$

as well as:

$$[P \wedge (Q \vee R)] = [(P \wedge Q) \vee (P \wedge R)] \tag{5.1.10}$$

Definition (#5.1.14): The "negation" operator $\neg$ transforms a True value into a False value such that:

$$\begin{gathered} \neg T = F \\ \neg F = T \end{gathered} \tag{5.1.11}$$

So in logic, negation, also named "logical complement", is an operation that takes a proposition P to another proposition "not P", denoted $\neg P$ or sometimes $\bar{P}$, which is interpreted intuitively as being True when P is false and False when P is True. Negation is thus a unary (single-argument) logical connective.

As we will prove it in detail in the section of Logic System page 7110 (using a simple truth table), the "De Morgan's laws" provide a way of distributing negation over disjunction and conjunction:

$$\begin{gathered} \neg(P \wedge Q) \Leftrightarrow [(\neg P) \vee (\neg Q)] \\ \neg(P \vee Q) \Leftrightarrow [(\neg P) \wedge (\neg Q)] \end{gathered} \tag{5.1.12}$$

Remark

To see the details of all logical operators, the reader should read the section of Logical Systems page 7104 where the identity, the double negative, the idempotence, associativity, the distributive properties, the De Morgan relations are presented more formally and with full details.

Let us now come back on the "logical implication connector" sometimes also named just the "conditional" denoted by the symbol $\Rightarrow$.

Remark

In some books on propositional calculus, this connector is denoted by the symbol $\supset$ and as part of the proof theory we often prefer the symbol $\rightarrow$.

Let P, Q two properties given on E. $P \Rightarrow Q$ is a property on E defined by:

P1. $P \Rightarrow Q$ is False if P is True and Q is False.

P2. $P \Rightarrow Q$ is True otherwise.

In other words, the fact that P logically implies Q means that Q is True for any assessment for which P is True. The implication is therefore the famous "if... then ...".

If we write the truth table of the implication (caution with the before last line!!!):

P	Q	$P \Rightarrow Q$
T	T	T
T	F	F
F	T	T
F	F	T

Table 5.7: **Implication truth table**

In other terms, a False proposition implies that any conclusion will always be True. This is named a "informal fallacy[1]" and it is a very important concept in null hypothesis statistical tests (see section Statistics page 948). If the proposition is True the implication can be True only if the result is True.

---

[1] A "paralogism" is a false argument that appears to be valid, especially to its author, who is honest, unlike a "sophism" which is a fallacious argument (a "fallacy") intended to deceive.

A given set of logical connectives is "truth functionally complete" if and only if all possible connectives can be expressed through suitable combinations of the ones in the given set.

It turns out the set of five logical connectives introduced in this chapter is truth functionally complete. In fact, the subset containing only the three connectives AND, OR, and NOT is also truth functionally complete. This means that you don't need the other two connectives-implication and equivalence-because you can express them in terms of NOT, AND, and OR:

$$\begin{aligned}(P \Rightarrow Q) &\text{ can be expressed as } (\neg P) \vee Q\\ (P \Leftrightarrow Q) &\text{ can be expressed as } (P \wedge Q) \vee (\neg P \wedge \neg Q)\end{aligned} \tag{5.1.13}$$

Although the set of connectives AND, OR, NOT is indeed both sufficient and convenient to express all possible compound predicates, you can achieve the same goal with even a single logical connective: the NAND operator (not and).

Remark

Strictly speaking, the above table should use the symbol $\rightarrow$, and the symbol $\Rightarrow$ should be reserved only for implications that are true.

Example:

Consider the proposition: "If you get your diploma, I buy you a computer".

Of all cases, only one corresponds to a broken promise: the one where the child graduates, and still has no computer (second line in the table above).

What means exactly this promise, that we will write as following:

$$\text{"You have your degree"} \Rightarrow \text{"I buy you a computer"?}$$

Exactly this:

- If you have get graduate, for sure, I will buy you a computer (I can not not buy it).
- If you do not get graduate, I said nothing.

The implication gives us that from any false proposition we can deduce any proposal (last two lines)!!!

Remark

Informal fallacy is very interesting to apply in the case of debates on social networks. Indeed, if someone ask you to prove your premise (null hypothesis) that he assumes to be false, then he didn't understand anything to logic as he should know that from any false premise (null hypothesis) you can always have a true conclusion (you don't reject the null hypothesis) whatever the reasoning! What the guy must do is assume your null hypothesis as true and found at least one example making it false (we reject the null hypothesis in favour of the alternative hypothesis). This is how science works and also the fact that this is not obvious explains why so many people loose their time to argue in social networks using biased arguments.

✍**Example:**

In a course taught by Russell on the subject from a false proposition, any proposal can be inferred, a student asked him the following question (anecdote or legend?):

- "Are you saying that from the proposition $2+2=5$, it follows that you are the Pope?".
- "Yes", answered Russell.
- "And could you prove it!", asked the student sceptical...
- "Certainly", answered Russell, who immediately offered the following proof:
  1. Suppose that $2+2=5$.
  2. Subtract 3 from each member of the equality, we thus get $1=2$.
  3. By symmetry $2=1$.
  4. The Pope and I are 2. Since $2=1$, Pope and I are 1. It follow I'm the Pope.

The implication connector is essential in mathematics, philosophy, etc. It is a backbone of any proof, evidence or deduction. It has the following useful properties (normally easy to check with a small truth table):

$$\begin{aligned} P \Rightarrow Q \Leftrightarrow [(\neg Q) \Rightarrow (\neg P)] \\ P \Rightarrow Q \Leftrightarrow [(\neg P) \vee Q] \end{aligned} \tag{5.1.14}$$

And we have from the last property (again verifiable by a truth table):

$$\neg(P \Rightarrow Q) \Leftrightarrow [P \wedge (\neg Q)] \tag{5.1.15}$$

The "logical equivalence connector" or "biconditional connector" denoted most of times by "$\Leftrightarrow$" or sometimes by "$\leftrightarrow$" meaning by definition:

$$(P \Leftrightarrow Q) \Leftrightarrow [(P \Rightarrow Q) \wedge (Q \Rightarrow P)] \tag{5.1.16}$$

in other words, the first expression has the same value for all evaluation of the second. It is the same with the following relation that is more "atomic" as the logical equivalence is reduced only to the use of $\wedge, \vee$ and negation $\neg$ (combination of what we have seen above):

$$(P \Leftrightarrow Q) \Leftrightarrow [(P \wedge Q) \vee (\neg P \wedge \neg Q)] \tag{5.1.17}$$

When we prove such equivalence of two expressions we can therefore say that: "we proves that the equivalence is a tautology".

A "necessary and sufficient condition" requires that both of the implications $P \Rightarrow Q$ and $Q \Rightarrow P$ (the latter of which can also be written as $P \Leftarrow Q$) hold. The first implication suggests that P is a sufficient condition for Q, while the second implication suggests that Q is a necessary condition for P. This is expressed as "Q is necessary and sufficient for P", "P if and only if Q", or $Q \Leftrightarrow P$.

The truth table of the equivalence is logically given by:

P	Q	$P \Rightarrow Q$	$Q \Rightarrow P$	$Q \Leftrightarrow P$
T	T	T	T	T
T	F	F	T	F
F	T	T	F	F
F	F	T	T	T

Table 5.8: **Truth table of the equivalence**

$P \Leftrightarrow Q$ means (when its true!) that "P and Q always have the same truth value" or "P and Q are equivalent." This is True if P and Q have the same value, False otherwise.

Of course (it is a tautology):

$$\neg(P \Leftrightarrow Q) \Rightarrow (P \Rightarrow \neg Q) \qquad (5.1.18)$$

The relation $P \Leftrightarrow Q$ is equivalent to that P is a necessary and sufficient condition for Q and that Q is a necessary and sufficient condition for P.

Remark

Strictly speaking, the above table should use the symbol $\leftrightarrow$, and the symbol $\Leftrightarrow$ should be reserved only for equivalences that are true.

The conclusion is that the conditions of the types: "necessary", "sufficient", "necessary and sufficient" can be reformulated with the terms "only if", "if", "if and only if".

Therefore:

1. $P \Rightarrow Q$ reflects the fact that Q is a necessary condition for P or in other words, P is True only if Q is True (in the truth table, when $P \Rightarrow Q$ is equal to T we see that P is T only if Q is also T). The assertion that Q is necessary for P is colloquially equivalent to "P cannot be true unless Q is true" or "if Q is false, then P is false".

2. $P \Leftarrow Q$ or what is the same $Q \Rightarrow P$ reflects the fact that Q is a sufficient condition for P or in other words, P is True if Q is True (in the truth table, when $Q \Rightarrow P$ takes the value T we see that P is T if Q is T too). If Q is sufficient for P, then knowing Q to be true is adequate grounds to conclude that P is true; however, knowing Q to be false does not meet a minimal need to conclude that P is false.

3. $P \Leftrightarrow Q$ reflects the fact that Q is a necessary and sufficient condition for P or in other words, P is True if and only if Q is True (in the truth table, when $P \Leftrightarrow Q$ takes the value T we see that P is 1 if Q is T and if and only if Q is equal to T).

Remark

The expression "if and only if" therefore corresponds to a logical equivalence and can only be used to describe a bi-implication !!

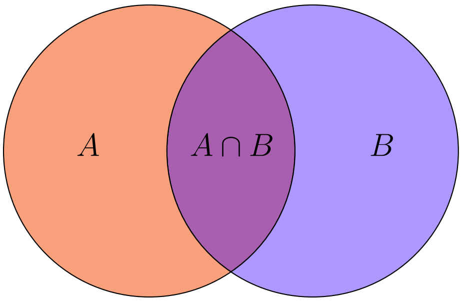
✍**Examples:**

E1. For the whole numbers greater than two, being odd is necessary to being prime, since two is the only whole number that is both even and prime.

E2. «John is a king» implies that John is male. So knowing that John is a king is sufficient to knowing that he is a male.

E3. A number's being divisible by 4 is sufficient (but not necessary) for it to be even, but being divisible by 2 is both sufficient and necessary for it to be even.

E4. Being in the purple region in the figure below is sufficient for being in A, but not necessary. Being in A is necessary for being in the purple region, but not sufficient. Being in A and being in B is necessary and sufficient for being in the purple region.



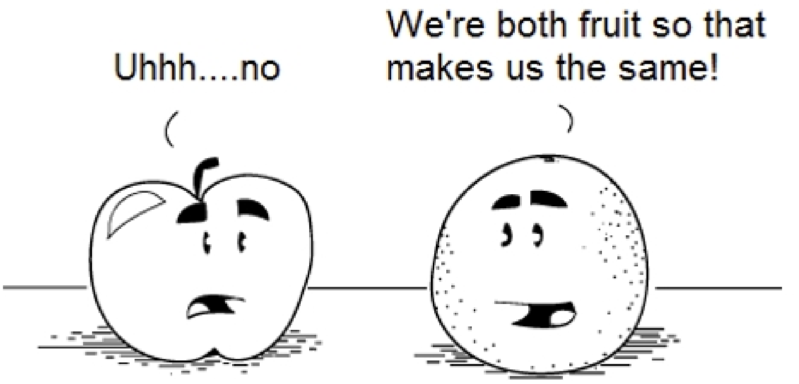
False equivalence is a logical fallacy in which an equivalence is drawn between two subjects based on flawed or false reasoning. This fallacy is categorized as a fallacy of inconsistency. Colloquially, a false equivalence is often named « *comparing apples and oranges* ».

This fallacy is committed when one shared trait between two subjects is assumed to show equivalence, especially in order of magnitude, when equivalence is not necessarily the logical result. False equivalence is a common result when an anecdotal similarity is pointed out as equal, but the claim of equivalence does not bear scrutiny because the similarity is based on oversimplification or ignorance of additional factors. The pattern of the fallacy is often as such:

If $\{x_1,\ldots,x_k,\ldots,x_n\} \in A$ and $\{x_1,\ldots,x_{k-m},\ldots,x_{k-m},\ldots,x_n\} \in B$ with $0 < m < n \in \mathbb{N}$, then since they both contain $\{x_1,\ldots,x_{k-m},x_{k-m},\ldots,x_n\}$ then $A = B$. Since $\{x_{k-m},\ldots,x_{k-m}\}$ is not required to exist in both sets; only a passing similarity is required to cause this fallacy to be used. More formally if $0 < m < n \in \mathbb{N}$:

$$(\{x_1,\ldots,x_k,\ldots,x_n\} \in A) \cap (\{x_1,\ldots,x_{k-m},\ldots,x_{k-m},\ldots,x_n\} \in B) \neq \varnothing \Rightarrow A \neq B \tag{5.1.19}$$

False equivalence arguments are often used on social networks, journalism, and in politics, where one strategical choice may be compared to flaws of a wholly different nature of another.



Uhhh....no
We're both fruit so that makes us the same!

The problem with popular articles, books or videos is that in the huge majority of cases the analogies to explain a concept are false equivalences.

Figure 5.3: **False equivalence fallacy**

Proof 5.0.1. Let two concepts or objects be represented by sets A and B. Each set contains the properties (or elements) that define the object:

$$A = \{a_1, a_2, \ldots, a_n\} \qquad B = \{b_1, b_2, \ldots, b_m\} \tag{5.1.20}$$

In set theory, equivalence (or identity) is defined by the axiom of extensionality. Two sets are equivalent if and only if they have exactly the same elements:

$$A = B \Leftrightarrow (\forall x, x \in A \Leftrightarrow x \in B) \tag{5.1.21}$$

This implies that $A \subseteq B$ and $B \subseteq A$. If even one property differs, the equivalence is broken.

An analogy does not assert total equality, but a non-empty intersection of specific properties in a given context.

If we draw an analogy between A and B based on a property P, this formally means:

$$\exists P : (P \in A \cap B) \tag{5.1.22}$$

However, by the very definition of analogy (which compares two different things), there exists a set of complementary non-empty properties:

- $A \backslash B \neq \varnothing$ (properties specific to A)
- $B \backslash A \neq \varnothing$ (properties specific to B)

To prove that an analogy is a false equivalence, we use the following reasoning:

1. **Analogy Hypothesis:**

   We set $A \approx B$ because they share the subset $S = A \cap B$.

2. **Equivalence Fallacy:**

   We attempt to assert that $A = B$ based solely on S.

3. **Contradiction :**

   Since this is an analogy and not an identity, there exists by definition an element x such that $x \in A$ but $x \notin B$ (or vice versa).

   Now, according to the definition of equivalence seen just above, if $x \in A$ and $x \notin B$, then $A \approx B$.

■ Q.E.D.

The first stage of propositional calculus is the formalization of natural language statements. To make this work, the propositional calculus finally provides three types of tools:

1. The "propositional variables" $(P, Q, R, \ldots)$ symbolize any simple proposals. If the same variable occurs multiple times, each time it symbolizes the same proposal.
2. The five logical operators: $\neg, \wedge, \vee, \Leftrightarrow, \Rightarrow$.
3. Punctuation are reduced to only opening and closing parentheses that organize reading so as to avoid ambiguity.

Here is a summary table:

Description	Symbol	Usage
The "Negation" is an operator that act only on one proposal; it is unary or monadic. "*It is not raining*" will be written $\neg P$. This statement is true if and only if P is false (in this case if it is false that it is raining). The conventional use of negation is characterized by the double negation law: $\neg\neg P$ is equivalent to P.	$\neg$	$\neg P$
The "conjunction" or "logical product" is a binary operator; it connects two proposals. "*Every man is mortal AND my car loses oil*" is written $P \wedge Q$. This latter expression is true if and only if P is true and Q is true.	$\wedge$	$P \wedge Q$
The "disconnection" or "logical sum" is also a binary operator. $P \vee Q$ is true if and only if P is true OR Q is true or both are true. We can understand the OR into two ways: either inclusively or exclusively. In the first case $P \vee Q$ is true if P is true, if Q is true or if P and Q are both true. In the second case, $P \vee Q$ is true if P is true or if Q is true but not if both are. The disjunction of propositional calculus is the inclusive OR and we give to the exclusive OR, that is to say the XOR, the name of "alternative".	$\vee$	$P \vee Q$
The "implication" or "inference" is also a binary operator. It corresponds roughly to the linguistic pattern "*If ... then ...*". "*If I have time, I will go see this movie*" will be written $P \Rightarrow Q$. This latter relation is false if P is true and Q is false. If the result (here Q) is true, the implication $P \Rightarrow Q$ is true. When the antecedent (here P) is false, the implication is always true. This latter remark can be understood if one refers to statements of the type: «*If we could put Paris in a bottle, the Eiffel Tower would be used as a plug*». In summary, an implication is false if and only if its antecedent is true and its consequent is false.	$\Rightarrow$	$P \Rightarrow Q$
The "bi-implication" or "equivalence" $\Rightarrow$ is, too, a binary operator: it symbolizes the terms "... *if and only if* ..." and "... *is equivalent to* ...". The equivalence of two propositions is true if they have the same truth value. The bi-implication therefore expressed as a form of identity, which is why it is often used in definitions.	$\Leftrightarrow$	$P \Leftrightarrow Q$

Table 5.9: Summary of logical core operators

And the corresponding summary truth table:

P	Q	$P \wedge Q$	$P \vee Q$	$P \Rightarrow Q$	$P \Leftrightarrow Q$	$\neg P$
T	T	T	T	T	T	F
T	F	F	T	F	F	F
F	T	F	T	T	F	T
F	F	F	F	T	T	T

Table 5.10: Truth table of main logical operators

The reader may read some authors that like to use at minimum the natural language in their books (...) and that use the symbol "$\therefore$" that is sometimes placed before a logical consequence, such as the conclusion of a syllogism. This symbol consists of three dots placed in an upright triangle and must be read as the word "*therefore*". We can also make use of the symbol "$\because$" that must be read as the word "*because*".

✍**Example:**

∵ All men are mortal.
∵ Socrates is a man.
∴ Socrates is mortal.

In this book we will however avoid using this notation as the engineers don't make use of that latter a lot.

It is possible to establish equivalences between these operators presented earlier. We have already seen how the biconditional could be defined as a product of reciprocal conditional, let us see now other equivalences:

$$\boxed{\begin{aligned}&(P\Rightarrow Q)\Leftrightarrow\neg(P\wedge\neg Q)\\&(P\Rightarrow Q)\Leftrightarrow(\neg P\vee Q)\\&(P\vee Q)\Leftrightarrow(\neg P\Rightarrow Q)\\&(P\wedge Q)\Leftrightarrow\neg(P\Rightarrow\neg Q)\end{aligned}}\tag{5.1.23}$$

Remark

The classical operators $\wedge,\vee,\Leftrightarrow$ can therefore be defined using the canonical operators $\neg,\Rightarrow$ through equivalence laws between them.

Also notice the two relations of De Morgan (see section of Boolean Algebra page 7110 for the proof):

$$\boxed{\begin{aligned}&\neg(P\vee Q)\Leftrightarrow(\neg P\wedge\neg Q)\\&\neg(P\wedge Q)\Leftrightarrow(\neg P\vee\neg Q)\end{aligned}}\tag{5.1.24}$$

that allow us to transform the disjunction into conjunction and vice versa:

$$\boxed{\begin{aligned}&(P\vee Q)\Leftrightarrow\neg(\neg P\wedge\neg Q)\\&(P\wedge Q)\Leftrightarrow\neg(\neg P\vee\neg Q)\end{aligned}}\tag{5.1.25}$$

To summarize the most classical laws of formal deductive logic:

Basics Laws of FOL	Formalism
Detachment (aka Modus Ponens)	$(p\rightarrow q)\wedge p\Rightarrow q$
Indirect reasoning (aka Modus Tollens)	$(p\rightarrow q)\wedge\neg q\Rightarrow\neg p$
Disjunctive addition	$p\Rightarrow(p\vee q)$
Conjunctive simplification	$(p\wedge q)\Rightarrow p$
Disjunctive simplification	$(p\vee q)\wedge\neg p\Rightarrow q$
Chain rule	$(p\rightarrow q)\wedge(q\rightarrow r)\Rightarrow(p\rightarrow r)$
Conditional equivalence	$p\rightarrow q\Leftrightarrow\neg p\vee q$
Biconditional equivalences	$(p\leftrightarrow q)\Leftrightarrow(p\rightarrow q)\wedge(q\rightarrow p)\Leftrightarrow(p\wedge q)\vee(\neg p\wedge\neg q)$
Contrapositive	$(p\rightarrow q)\Leftrightarrow(\neg q\rightarrow\neg p)$

Table 5.11: **Basics Deductive Logical Laws - Common Implications and Equivalences**

A part of the above table is often represented differently:

Rule of inference	**Name**	**Rule of inference**	**Name**
$\begin{array}{r} \neg q \\ p \to q \\ \hline \therefore \neg p \end{array}$	Modus Tollens	$\begin{array}{r} p \\ \hline \therefore p \lor q \end{array}$	Disjunctive amplification
$\begin{array}{r} p \\ p \to q \\ \hline \therefore q \end{array}$	Modus Ponens	$\begin{array}{r} \neg p \to \text{False} \\ \hline \therefore p \end{array}$	Contradiction
$\begin{array}{r} p \land q \\ \hline \therefore p \end{array}$	Simplification	$\begin{array}{r} p \land q \\ p \to (q \to r) \\ \hline \therefore (p \lor q) \to r \end{array}$	Conditional proof
$\begin{array}{r} p \\ q \\ \hline \therefore p \land q \end{array}$	Conjuction	$\begin{array}{r} p \to r \\ q \to r \\ \hline \therefore (p \lor q) \to r \end{array}$	Proof by cases
$\begin{array}{r} p \lor q \\ \neg p \\ \hline \therefore q \end{array}$	Disjunctive syllogism	$\begin{array}{r} p \to q \\ q \to r \\ \hline \therefore p \to r \end{array}$	Law of syllogism

5.1.3.3 Decision procedures

We have previously introduced the basic elements allowing us to operate on expressions from properties (propositional variables) without saying much about the handling of such expressions. So now you need to know that in propositional calculus there are two ways to establish that a proposition is a law of propositional logic. We can either:

1. Use non-automated procedures
2. Use axiomatic and demonstrative procedures

Remark

In many books these procedures are presented before the structure of the propositional language. We chose here to do the opposite thinking that the approach would be easier.

5.1.3.3.1 Non-axiomatic procedural decisions

Several of these methods exist, but we will limit ourselves here to the simplest of them, that of the matrix calculation, often referred to as "methods of truth tables".

The construction procedure is as we have already seen quite simple. Indeed, the truth value of a complex expression is a function of the truth value of the simple statements that compose it, and finally based on the truth value of propositional variables that makes it. Considering all possible combinations of truth values of propositional variables, we can determine the truth values of the complex expression.

Truth tables, as we have seen it, gives us the possibility to decide, about any proposition, if this latter is a tautology (always true), a contradiction (always false) or a contingent expression (sometimes true, sometimes false).

We can distinguish at least four ways to combine propositional variables, brackets and connectors:

	Name	Description	Example
1	Malformed statement	Nonsense. Neither true nor false	$(\vee P)Q$
2	Tautology	Statement always true	$P \vee \neg P$
3	Contradiction	Statement always false	$P \wedge \neg P$
4	Contingent statement	Statement sometimes true, sometimes false	$P \vee Q$

Table 5.12: **Combination of propositional variables**

The method of truth tables helps to determine the type of expression that are well-formed to which we have to face. It requires, in principle, no invention, it is "only" a mechanical procedure. Axiomatized procedures, however, are not entirely mechanical. Inventing a proof as part of an axiomatized system requires sometimes hability, practice or luck. Regarding to truth tables, here is the protocol to follow:

When facing a well-formed expression, or function of truth, we first determine how many distinct propositional variables we are dealing with. We then examine the various arguments that form this expression. We then construct a table with 2^n columns (n being the number of variables and without forgetting that they are binary variables!) and a number of columns equal to the number of arguments plus columns for the expression itself and its other components (see previous examples). Then we assign to the variables the various combinations of True (1) and False (0) values that may be conferred upon them. Each row corresponds to a possible outcome and all of the rows is the set of all possible outcomes. There is, for example, a possible outcome wherein P is a true statement while Q is false.

5.1.3.3.2 Axiomatic procedural decisions

The axiomatization of a theory implies, besides its formalization, that we start form a finite number of axioms and that through the controlled transformation of these, we can get all the theorems of this theory. So we start from a few axioms whose truth is a statement (not proven). We determine afterwards deduction rules for manipulating the axioms or expression obtained from these. The sequence of these deductions is a proof that leads to a theorem, a law or lemma.

We will now briefly present two axiomatic systems, each consisting of axioms using two specific rules named "inference rules" (intuitive rules):

1. The "modus ponens": If we prove A and $A \Rightarrow B$, then we can deduce B. A is named the "minor premise" and $A \Rightarrow B$ the "major premise" of the modus ponens rule.

   ✍**Example:**

   From:

   $$x>y$$

   and:

   $$(x>y)\Rightarrow(y<x)$$

   we can deduce that:

   $$y<x$$

   Remark

   Humans typically communicate in a way that resists shallow logical analysis. In a real conversation, people use words rather than terms, make utterances rather than sentences, and employ a wider variety of inference methods than modus ponens. A great deal of what is communicated and inferred in a conversation depends on context, the speakers and audience, their history, their shared knowledge and confidences, the feelers they lay out to establish mutual trust and rapport.

2. The "substitution": we can in a schema of axioms replace a letter by any formula, at the condition that all identical letters are replaced by identical formulas!

   Let us give as an example, two axiomatic systems: the axiomatic system of Whitehead and Russell, the axiomatic system of Lukasiewicz.

   (a) The axiomatic system of Russell and Whitehead adopts $\neg, \vee$ as primitive symbols and define $\Rightarrow, \wedge, \Leftrightarrow$ from these latter as follows (easily verifiable relations with truth tables):

$$\boxed{\begin{aligned}&(A \Rightarrow B) \Leftrightarrow \neg A \vee B\\&(A \wedge B) \Leftrightarrow \neg(\neg A \vee \neg B)\\&(A \Leftrightarrow B) \Leftrightarrow (A \Rightarrow B) \wedge (B \Rightarrow A)\end{aligned}} \tag{5.1.26}$$

This system includes 5 axioms, somewhat quite obvious plus two rules of inference. Axioms are given here using non-primitive symbols, as did Whitehead and Russell:

A1. $(A \vee A) \Rightarrow A$
A2. $B \Rightarrow (A \vee B)$
A3. $(A \vee B) \Rightarrow (B \vee A)$
A4. $(A \vee (B \vee C)) \Rightarrow (B \vee (A \vee C))$
A5. $(B \Rightarrow C) \Rightarrow ((A \vee B) \Rightarrow (A \vee C))$

we have already presented above some of these.

Remark

These five axioms are not independent of each other. The fourth can be obtained from the other four.

For example, to justify that $\neg A \vee A$ has a sense[2], we can proceed as following (in this system we only prove logical truths, meaning that every line need to be a logical truth by itself):

(1)	$B \Rightarrow (A \vee B)$	Axiom A2
(2)	$A \Rightarrow (A \vee A)$	(1) and substitution
(3)	$(B \Rightarrow C) \Rightarrow ((A \vee B) \Rightarrow (A \vee C))$	Axiom A5 (necessary)
(4)	$(B \Rightarrow C) \Rightarrow ((\neg A \vee B) \Rightarrow (\neg A \vee C))$	(3) and substitution
(5)	$(B \Rightarrow C) \Rightarrow ((A \Rightarrow B) \Rightarrow (A \Rightarrow C))$	(4) and property of $\Rightarrow$
(6)	$((A \vee A) \Rightarrow A) \Rightarrow ((A \Rightarrow (A \vee A)) \Rightarrow (A \Rightarrow A))$	(5) and substitution
(7)	$(A \Rightarrow (A \vee A)) \Rightarrow (A \Rightarrow A)$	(6) (modus ponens)
(8)	$(A \Rightarrow A) \Rightarrow (A \Rightarrow A)$	(7) and axiom A1
(9)	$A \Rightarrow A$	(8) and modus ponens
(10)	$\neg A \vee A$	(9) and property of $\Rightarrow$

(b) The axiomatic system of Lukasiewicz includes three axioms, plus the two rules of inference (modus ponens and substitution):

A1. $(A \Rightarrow B) \Rightarrow ((B \Rightarrow C) \Rightarrow (A \Rightarrow C))$
A2. $A \Rightarrow (\neg A \Rightarrow B)$
A3. $(\neg A \Rightarrow A) \Rightarrow A$

Here is the proof of the first two axioms in the system of Russell and Whitehead. These are the formulas (6) and (16) of the following derivation:

---

[2] It's named the "law of the excluded middle": A proposition is either true or false. This has been widely held to be self-evident for thousands of years

(1)	$(A \vee (B \vee C)) \Rightarrow (B \vee (A \vee C))$	Axiom A4
(2)	$(\neg(B \Rightarrow C) \vee (\neg(A \vee B) \vee (A \vee C))) \Rightarrow (\neg(A \vee B) \vee (\neg(B \Rightarrow C) \vee (A \vee C)))$	(1) and substitution
(3)	$\neg(A \vee B) \vee (\neg(B \Rightarrow C) \vee (A \vee C))$	A4 on (2) and modus ponens
(4)	$(A \vee B) \Rightarrow ((B \Rightarrow C) \Rightarrow (A \vee C))$	(3) by the property of $\Rightarrow$
(5)	$(\neg A \vee B) \Rightarrow ((B \Rightarrow C) \Rightarrow (\neg A \vee C))$	(4) and substitution
(6)	$(A \Rightarrow B) \Rightarrow ((B \Rightarrow C) \Rightarrow (A \Rightarrow C))$	(5) and property of $\Rightarrow$
(7)	$(B \Rightarrow (A \vee B)) \Rightarrow \begin{pmatrix} ((A \vee B) \Rightarrow (B \vee A)) \\ \Rightarrow (B \Rightarrow (B \vee A)) \end{pmatrix}$	(6) and substitution
(8)	$((A \vee B) \Rightarrow (B \vee A)) \Rightarrow (B \Rightarrow (B \vee A))$	(7) modus ponens
(9)	$B \Rightarrow (B \vee A)$	(8) modus ponens
(10)	$\neg B \Rightarrow (\neg B \vee A)$	(9) and substitution
(11)	$\neg\neg B \vee (\neg B \vee A)$	(10) and property of $\Rightarrow$
(12)	$\neg\neg B \vee (\neg B \vee A) \Rightarrow (\neg B \vee (\neg\neg B \vee A))$	A4 + substitution with (11)
(13)	$\neg B \vee (\neg\neg B \vee A)$	(12) and modus ponens
(14)	$B \Rightarrow (\neg\neg B \vee A)$	(19) and property of $\Rightarrow$
(15)	$B \Rightarrow (\neg B \vee A)$	(14) and property of $\Rightarrow$
(16)	$A \Rightarrow (\neg A \Rightarrow B)$	(15) and substitution

These axiomatizations let us found as theorems all tautologies or laws of the propositional logic. From everything that has been said so far, we can try to define what is a proof!!!!

Definition (#5.1.15): A finite sequence of formulas $B_1, B_2, \ldots, B_m$ is named a "proof" from the assumptions/hypothesis $A_1, A_2, \ldots, A_n$ if for each i:

- B_i is one of the assumptions/hypothesis $A_1, A_2, \ldots, A_n$
- or B_i is a variant of an axiom
- or B_i is inferred (by the application of the modus ponens rule) from the major premise B_j and minor premise B_k where $j, k < i$
- or B_i is inferred (by the application of the substitution rule) from an anterior premise B_j, the replaced variable not appearing in $A_1, A_2, \ldots, A_n$

Such a sequence of formulas, B_m being the final formula of the sequence, is more explicitly named "proof of B_m" from the assumptions/hypothesis (or axioms) $A_1, A_2, \ldots, A_n$, what we also write:

$$\boxed{A_1, A_2, \ldots, A_n \vdash B_m} \tag{5.1.27}$$

More explicitly a proof is a deductive argument for a mathematical statement. In the argument, other previously established statements, such as theorems, can be used. In principle, a proof can be traced back to self-evident or assumed statements, known as axioms.

Proofs employ logic but usually include some amount of natural language which usually admits some ambiguity. In fact, the vast majority of proofs in written mathematics can be considered as applications of rigorous informal logic. Purely formal proofs, written in symbolic language instead of natural language, are considered in proof theory.

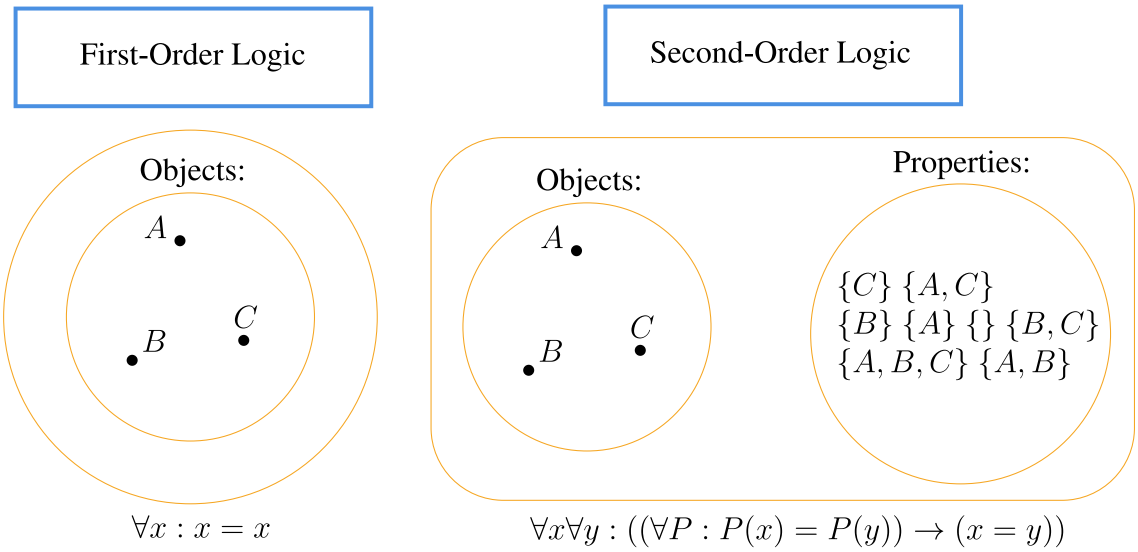
Remark

Note that when we try to prove a result from a number of assumptions, we do not try to prove the assumptions themselves!

5.1.3.4 Quantifiers

We have to complete the use of the connectors of propositional calculus by what we name "quantifiers" if we wish to solve some problems. Indeed, the propositional calculus does not allow us to state general things about the elements of a set, for example. In that sense, propositional logic is only part of the reasoning. The calculus of predicates on the contrary allows to formally handle statements such as "there exists an x such that [x has an American car]" or "for all x [if x is a dachshund, then x is small]". In short, we extend the composed formulas in order to assert existential quantifiers ("there...") and universal quantifiers ("for every..."). The examples we just gave involve a bit special proposals like "x has an American car." This is proposition with a variable. These proposals are in fact the application of a function to x. This function, is this that associates "x has an American car" with x. We will denote this function by "... has an American car" and we say that is a propositional function because it is a function whose value is a proposal. Or a "predicate" as we already know.

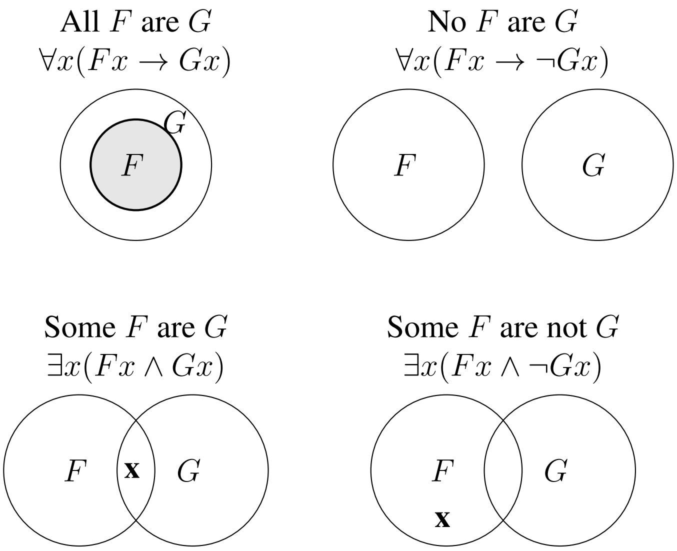
The existential and universal quantifiers go hand in hand with the use of propositional functions. The predicate calculus is however limited in the existential and universal formulas. Thus, we prohibit ourselves to use sentences like "there is an affirmation of x such that ...". In fact, we allow ourselves to quantify only "individuals". This is why predicate logic is named "first-order logic" (FOL) or "first-order predicate logic" (FOPL) because it uses variables as basic mathematical objects (while in the second-order logic they can also be sets).



Before going back to the study of the predicate calculus we define:

D1. The "universal quantifier": $\forall$ (for all)

D2. The "existential quantifier": $\exists$ (exists)



All F are G
$\forall x(Fx \rightarrow Gx)$
G
F
No F are G
$\forall x(Fx \rightarrow \neg Gx)$
F
G
Some F are G
$\exists x(Fx \wedge Gx)$
F
x
G
Some F are not G
$\exists x(Fx \wedge \neg Gx)$
F
G
x

Figure 5.4: **The four standard types of quantified statements**

✍**Example:**

If any complex number is the product of a non-negative number and a number of modulus 1 we will write:

$$\forall z \in \mathbb{C}, \exists p \in \mathbb{Z} \geq 0, \exists u \in \mathbb{C} : \quad (|u| = 1 \wedge z = pu) \tag{5.1.28}$$

The order of quantifiers is critical to meaning, as illustrated by the following two propositions (by the way it's a good test to check if someone know the basics of logic):

For every natural number n, there exists a natural number s such that $s = n^2$.
$\forall n \in \mathbb{N}, \exists s \in \mathbb{N}, s = n^2$

This is clearly true! It just asserts that every natural number has a square. The meaning of the assertion in which the quantifiers are turned around is different:

There exists a natural number s such that for every natural number n, $s = n^2$.
$\exists s \in \mathbb{N}, \forall n \in \mathbb{N}, s = n^2$

This is clearly false! It asserts that there is a single natural number s that is at the same time the square of every natural number.

A frequent question in physics and mathematics is to know if the universal quantifier has to be before of after the predicates they refer to. In fact, strictly in terms of formal logic, quantifiers are always at the beginning of any formula. However, almost no one gives a proof that is written in the formal language. Even simple proofs would be very long and unreadable. But anyone, regardless of what natural language they speak, will interpret a sentence in the formal language in the same way. The price for this clarity of course is readability. Natural languages, because of their inherent ambiguity, are subject to many more limitations.

Obviously the proper usage of a formal notation or of a more informal one depends particularly on the context of presentation. It is essential to whom we communicate an idea and this should guide us to use a suitable level of formal notation.

We use the sometimes the symbol ∃! to say briefly: "there is one and only one".

✍**Example:**

A famous example is the way to explicit that the logarithm is a bijective function:

$$\forall x \in \mathbb{R}^{+}, \exists ! y \in \mathbb{R}_{+}^{*}: \quad x=\ln (y) \tag{5.1.29}$$

Suppose now we claim that there is no smallest number in $\mathbb{R}$. We can translate this into symbols as:

$$\neq \exists x \in \mathbb{R} \forall y \in \mathbb{R}:(x \leq y) \tag{5.1.30}$$

Literally: «it is not true that there is a real number x such tat for all real numbers y, x is less than or equal to y».

However, we can negate quantifiers: we can pass a negation over a quantifier by switching the quantifier type (between universal and existential). So the statement above should be logically equivalent to:

$$\forall x \in \mathbb{R} \exists y \in \mathbb{R}:(y<x) \tag{5.1.31}$$

Notice that $y<x$ is the negation of $x \leq y$. This literally says: «for every real number x there is a real number y which is small than x». We see that this is another way to make our original claim.

Before moving to predicate calculus, let us have a non exhaustive summary that is common in the literature and uses negation:

Expression		Is equivalent to
$\neg\neg A$	$\Leftrightarrow$	A
$\neg A \Rightarrow \neg B$	$\Leftrightarrow$	$B \Rightarrow A$
$\neg A \Rightarrow B$	$\Leftrightarrow$	$\neg B \Rightarrow A$
$A \Rightarrow \neg B$	$\Leftrightarrow$	$(A \wedge B) \Rightarrow F$
$\neg A \wedge \neg B$	$\Leftrightarrow$	$\neg(A \vee B)$
$A \wedge \neg B$	$\Leftrightarrow$	$\neg(\neg A \vee B)$
$\wedge A \neg B$	$\Leftrightarrow$	$\neg(A \vee \neg B)$
$\neg A \vee \neg B$	$\Leftrightarrow$	$\neg(A \wedge B)$
$A \vee \neg B$	$\Leftrightarrow$	$\neg(\neg A \wedge B)$
$\neg A \vee B$	$\Leftrightarrow$	$\neg(A \wedge \neg B)$
$\neg(\exists x \in X : \neg P(x))$	$\Leftrightarrow$	$(\forall x \in X : P(x))$
$(\exists x \in X : \neg P(x))$	$\Leftrightarrow$	$\neg(\forall x \in X : P(x))$
$(\exists x \in X : P(x))$	$\Leftrightarrow$	$(\forall x \in X : \neg P(x))$
$(\exists x \in X : P(x))$	$\Leftrightarrow$	$\neg(\forall x \in X : \neg P(x))$

We will see now that the Proof Theory and Set Theory are the exact transcription of the principles and results of Logic (the one with a capitalized "L"!!!).

5.1.4 Predicate Calculus

In mathematics courses (algebra, analysis, geometry, ...), we prove the properties of different object types (integer, real, matrices, sequences, continuous functions, curves, triangles, ...). To prove these properties, we need of course that the objects on which we work are clearly defined (what is a set, what is a real, what is point, ...?).

In first-order logic and, in particular, in proof theory, the objects we study are the formulas and proofs. We must therefore give a precise definition of what are these objects. The terms and formulas are the grammar of a language, oversimplified and calculated exactly to say what we want without ambiguity and without unnecessary detour.

In the previous sections we saw that syllogistics treats sentences differently than propositional logic. Syllogistics is concerned with the components of sentences, notably the quantifiers «all», «none» and «some», while propositional logic abbreviates any sentence – regardless of its components – with letters like « p », « q », « r », etc. Thus, propositional logic is not capable of explaining the validity of inferences from typical human rhetorical sentences.

Propositional logic does not allow us to explain the validity of rhetorical inferences, because it does not take into account the internal structure of the simple sentences it processes: it treats « p » and « q » as atoms and does not analyze their internal structure.

To formalize rhetorical inferences and explain their validity, it is necessary to use the notion of predicate and convert the concepts into algebraic letters. For example, the following inference:

$$\begin{array}{c}\text{All humans are mortal}\\ \text{All philosophers are humans}\\ \hline \text{All philosophers are mortal}\end{array} \tag{5.1.32}$$

Therefore becomes:

$$\begin{array}{c}\text{All the } M \text{ are } P\\ \text{All the } S \text{ are } M\\ \hline \text{All the } S \text{ are } P\end{array} \tag{5.1.33}$$

If we abbreviate « all the . . . are . . . » by « $\forall x(\ldots x\ldots \rightarrow \cdots x\ldots)$ », we get :

$$\begin{array}{c}\forall x(Mx \rightarrow Px)\\ \forall x(Sx \rightarrow Mx)\\ \hline \forall x(Sx \rightarrow Px)\end{array} \tag{5.1.34}$$

Thus we have converted the syllogism into a valid inference!

Remark

In standard first-order logic, the statement « *All men are mortals* » is written as $\forall x(M(x) \rightarrow \text{Mortal}(x))$. In standard logic, saying « *It is false that all men are mortal* » (written technically $\neg\forall x(M(x) \rightarrow \text{Mortal}(x))$) means exactly the same thing as saying « *There is at least one man who is not mortal* »: $\exists x(M(x) \rightarrow \neg\,\text{Mortal}(x))$.

5.1.4.1 Grammar

Definitions (#5.1.16):

D1. The "terms" designate items for which we want to prove some properties (we will discussed the latter much more in details further below):

- In algebra, the terms refer to the elements of a set (group, ring, field, vector space, etc.). We also manipulate sets of objects (subgroups, subrings, subfields, etc.). The terms which will designate the objects are named "second-order terms".
- In analysis, the terms refer most of time to real numbers (for example, if we put ourselves in functional spaces) or functions.

D2. The "formulas", are the properties of objects we study (we will discussed the latter also much more in details further below):

- In algebra, we can write formulas to express that two elements commute, that a subspace is of dimension 3, etc.
- In analysis, we will write formulas to express the continuity of a function, the convergence of a sequence, etc.
- In set theory, formulas can express inclusion of two sets, membership of an element in a set, etc.

D3. The "proof", enable to check if a formula is true. The precise meaning of this word will also need to be defined. More precisely, they are deductions under assumptions, they allow to "lead from truth to truth", the question of the truth of the conclusion is then returned to that of the hypothesis, which does not look at the logic but is based on the knowledge we have on things we talk about.

5.1.4.2 Languages

In mathematics we use, depending on the area, different languages that are distinguished by the symbols used. The definition below simply expresses that it is sufficient to only have to give the list of symbols to specify the language.

Definition (#5.1.17): A "language" is the content of a family (not necessarily finite) of symbols. We distinguish three kinds of languages: symbols, terms and formulas.

Remarks

R1. We use sometimes the word "vocabulary" or "signature" instead of the word "language".

R2. We already know that the word "predicate" is used instead of the word "relation". We speak then of "predicate calculus" instead of "first-order logic").

5.1.4.2.1 Symbols

There are different types of symbols we will try to define!

Definitions (#5.1.18):

D1. The "constant symbols" (see note below)

✍**Example:**

The neutral element n in Set Theory (see section Set Theory page 417)

D2. The "function symbols" or "functors". To each function symbol is assigned a strictly positive integer that we name the "arity": this is the number of arguments of the function arguments. If the arity is 1 (resp. $2, \ldots, n$), we say then that the function is unary (resp. binary, ..., n-ary).

✍**Example:**

The binary functor of multiplication $\times$ or $\cdot$ in group theory (see section Set Theory page 436) is 2-ary or more commonly a "binary" operator.

D3. The "relation symbol". Similarly to the previous definition, every relation symbol is associated with a positive or null integer (its arity) that corresponds to its number of arguments and we talk then of unary, binary, n-ary relation.

✍**Example:**

The relation $=$ is a binary relation (see section Operators page 287)

D4. The "individual variables". In what will follow we will give us an infinite set $\mathcal{V}$ of variables. The variables will be recorded as it is traditional by the latin lowercase letters: x, y, z (possibly indexed: x_1, x_2, x_3).

D5. To this we should add the connectors $\neg, \Rightarrow, \vee, \wedge$ and quantifiers $\forall, \exists, \exists!$ that we extensively discussed above, on which it is now useless to return.

Remarks

R1. A constant symbol can be seen as a function symbol with 0 argument (arity zero).

R2. We consider (unless otherwise stated) that each language contains the binary relation symbol $=$ (read "equal") and the relation symbol with zero argument denoted $\perp$ (read "bottom" or "absurd/contradiction") represents the value FALSE and $\top$ (read "top or "tautology") represents the value TRUE. In the description of a language, we will often omit to mention them. The symbol $\perp$ is often redundant. We can indeed, without using it, write a formula that is always false. However, it can represent the FALSE in a canonical way and therefore gives the possibility to write general proof rules.

R3. The role of functions and relations is very different. As we will see, the function symbols are used to construct the terms (of language objects) and the relation symbols to build formulas (the properties of these objects).

5.1.4.2.2 Terms

The terms, we also say the "first order terms", are the objects associated with the language.

Definitions (#5.1.19):

D1. Given $\mathcal{L}$ a language, the set $\mathcal{T}$ of terms on $\mathcal{L}$ is the smallest set containing the variables, the constants and stable (we do not go out of the set) by applying function symbols of $\mathcal{L}$ to the terms.

D2. A "closed term" is a term that does not contain variables (by extension, only constants).

D3. For a more formal definition, we can write:

$$\mathcal{T}_0 = \{t\} \tag{5.1.35}$$

where t is a variable or constant symbol and, for any $k \in \mathbb{N}$:

$$\mathcal{T}_{k+1} = \mathcal{T}_k \cup \{f(t_1, \ldots, t_n) | t_i \in \mathcal{T}_k\} \tag{5.1.36}$$

where f is obviously a function of arity n (let us recall that the arity is the number of function arguments). Thus, for each arity, there is a degree of set of terms. We have finally:

$$\mathcal{T}=\bigcup_{k\in\mathbb{N}}\mathcal{T}_k \tag{5.1.37}$$

D4. We name "height" of a term t the smallest k such that $t\in\mathcal{T}_k$.

This definition means that variables and constants are terms and that if f is a n-ary function symbol and $t_1,\ldots,t_n$ are terms then $f(t_1,\ldots,t_n)$ is also a term itself. The set $\mathcal{T}$ of terms is defined by the grammar:

$$\boxed{\mathcal{T}=\{V|S_c|S_f(\mathcal{T},\ldots,\mathcal{T})\}} \tag{5.1.38}$$

This expression must be read as follows: a element of the set $\mathcal{T}$ we are defining is either an element of V (variable) or an element of S_c (the set of symbols of constant), or the application of a n-ary function symbol $f\in S_f$ (constants or variable) of $\mathcal{T}$.

Caution! The fact that f is of the good arity is only implicit in this notation. Moreover, writing $S_f(\mathcal{T},\ldots,\mathcal{T})$ does not mean that all function arguments are identical, but simply that these arguments are elements of $\mathcal{T}$.

Remark

It is often convenient to see a term (expression) as a tree, where each node is labelled with a function symbol (operator or function) and each sheet by a variable or constant.

In what follows, we will almost always define concepts (or prove results) "by recurrence" (see page 218) on the structure or the size of a term.

Definitions (#5.1.20):

D1. To prove a property P on the terms, it suffices to prove P for the variables and constants and to prove $P(f(t_1,\ldots,t_n))$ from $P(t_1),\ldots,P(t_n)$. We do then here a "proof by induction on the height of a term". It is a technique that we will find in the following chapters.

Mathematical induction as an inference rule can be formalized as a second-order axiom. The axiom of induction is, in logical symbols:

$$\forall P.\,[[P(0)\wedge\forall(k\in\mathbb{N}).\,[P(k)\Rightarrow P(k+1)]]\Rightarrow\forall(n\in\mathbb{N}).\,P(n)] \tag{5.1.39}$$

In words, the basis $P(0)$ and the inductive step (namely, that the inductive hypothesis $P(k)$ implies $P(k+1)$) together imply that $P(n)$ for any natural number n. The axiom of induction asserts that the validity of inferring that $P(n)$ holds for any natural number n from the basis and the inductive step.

Induction can be compared to falling dominoes: whenever one domino falls, the next one also falls. The first step, proving that $P(1)$ is true, starts the infinite chain reaction.

D2. To define a function Φ based on the terms, it is enough to define it on the variables and constants and tell how we get $\Phi(f(t_1,\ldots,t_n))$ from $\Phi(t_1),\ldots,\Phi(t_n)$. We do here again a "definition by induction on the height of a term".

✍**Example:**

The size (we also say the "length") of a term t (size denoted $\tau(t)$) is the number of function symbols occurring in t. formally:

- $\tau(x)=\tau(c)=0$ if x is a variable and c is a constant.
- $\tau(f(t_1,\ldots,t_n))=1+\sum\limits_{i\leq i\leq n}\tau(t_i)$

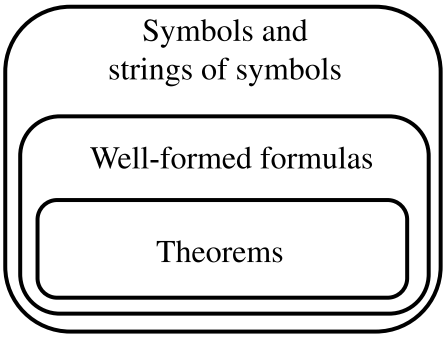
where the 1 in the last relation represents the term f itself.

5.1.4.2.3 Formulas

Definition (#5.1.21): A "well-formed formula" (WFF), often simply "formula" is a word (i.e. a finite sequence of symbols from a given alphabet) that is part of a formal language. A formal language can be considered to be identical to the set containing all and only its formulas.

The formulas of propositional calculus, also named "propositional formulas", are expressions such as $(A\wedge(B\vee C))$.

An atomic formula is a formula that contains no logical connectives nor quantifiers, or equivalently a formula that has no strict sub-formulas. The precise form of atomic formulas depends on the formal system under consideration; for propositional logic, for example, the atomic formulas are the propositional variables. For predicate logic, the atoms are predicate symbols together with their arguments, each argument being a term.



Definition (#5.1.22): Formulas are built from "atomic formulas" using connectors and quantifiers. We will use the following connectors and quantifiers (which we already known):

- Unary negation connector: $\neg$
- Binary connectors of conjunction and disjunction and implication: $\wedge,\vee,\rightarrow$
- Quantifiers: $\exists$ which must be read "it exists" and $\forall$ that must be read "for all"

This notation of the connectors is almost (it should at least). It is used to avoid confusion between the formulas and the current language (metalanguage).

Definitions (#5.1.23):

D1. Given $\mathcal{L}$ a language, the "atomic formulas" of $\mathcal{L}$ are the formulas of the form $R(t_1,\ldots,t_n)$ where R is an n-ary relation symbol of $\mathcal{L}$ of and $t_1,\ldots,t_n$ are terms of $\mathcal{L}$. We denote by "Atom" all atomic formulas. If we denote by S_r the set of relation symbols, we can write all terms related between them by the expression:

$$\boxed{\text{Atom} = S_R(\mathcal{T},\ldots,\mathcal{T})\quad \mathcal{T}\in\mathcal{L},\forall t_i\in\mathcal{T}}\tag{5.1.40}$$

The set $\mathcal{F}$ of formulas of the first order logic of $\mathcal{L}$ is thus defined by the grammar (where x is a variable):

$$\boxed{\mathcal{F} = \text{Atom}|F\wedge F|F\vee F|F\rightarrow F|F\neg F|\exists x\mathcal{F}|\forall x\mathcal{F}}\tag{5.1.41}$$

where should be read: the set of formulas is the smallest set containing formulas and such that if F_1 and F_2 are formulas then $F_1\vee F_2$, etc. are formulas and can be related to each other.

✍**Example:**

The relations symbols of the propositional language are relations of 0-arity (even the symbol "$=$" is absent), the quantifiers are then useless (since a propositional formula can not contain variables). We then obtain the propositional calculus $\mathcal{C}_P$ defined by:

$$\boxed{\mathcal{C}_P = V_P|\bot|\neq\mathcal{C}_P|\mathcal{C}_P\vee\mathcal{C}_P|\mathcal{C}_P\wedge\mathcal{C}_P|\mathcal{C}_P\rightarrow\mathcal{C}_P}\tag{5.1.42}$$

Note the presence of the symbol "bottom" $\bot$ meaning the "false" that we did not mention in our previous study of propositional logic.

The reader must be careful to not to confuse terms and formulas. $\sin(x)$ is a term (function), $x=3$ is a formula. But $\sin(x)\wedge(x=3)$ is nothing: we can not, in fact, put a connector between a term and a formula (meaningless).

Remarks

R1. To define a function Φ based on formulas, we simply need to define Φ on atomic formulas.

R2. To prove a property P on formulas, it suffices to prove P for the atomic formulas.

R3. To prove a property P on the formulas, it is enough assume that the property holds for all formulas of size $p < n$ and to prove the property for formulas of size n.

D2. A "sub-formula" of a formula (or expression) F is one of its components, verbatim a formula from which F is built. Formally, we define the set $\text{SF}(F)$ of the sub-formulas F by:

- If F is atomic:

$$\text{SF}(F)=\{F\} \tag{5.1.43}$$

- If $F=F_1\oplus F_2$ (that is to say a composition) with $\oplus\in\{\vee,\wedge,\rightarrow\}$:

$$\text{SF}=(F)=\{F\}\cup\text{SF}(F_1)\cup\text{SF}(F_2) \tag{5.1.44}$$

- If $F=\neg F$ or $\text{Q}\in F_1$ with $\text{Q}\in\{\forall,\exists\}$:

$$\text{SF}(F)=\{F\}\cup\text{SF}(F_1) \tag{5.1.45}$$

D3. A formula F of $\mathcal{L}$ uses only a finite number of symbols of $\mathcal{L}$. This subset is named the "language of the formula" and is denoted by $\mathcal{L}(F)$.

D4. The "size (or length) of a formula F", denoted by $\tau(F)$ is the number of connectors or quantifiers occurring in F. Formally:

- $\tau(F)=0$ if F is an atomic formula
- $\tau(F_1\oplus F_2)=1+\tau(F_1)+\tau(F_2)$ where once again $\oplus\in\{\vee,\wedge,\rightarrow\}$
- $\tau(\neg F_1)=\tau(\text{Q}xF_1)=1\tau(F_1)$ with once again $\text{Q}\in\{\forall,\exists\}$

D5. The "main operator" (we also say the "main connector") of a formula is defined as:

- If A is atomic, so it has then it has no main operator
- If $A=\neg B$, the $\neg$ is the main operator of A
- If $A=B\oplus C$ where once again $\oplus\in\{\vee,\wedge,\rightarrow\}$ then $\oplus$ is the main operator of A
- If $A=\text{Q}xB$ where once again $\text{Q}\in\{\forall,\exists\}$, then Q is the main operator of A

D6. Given F a formula. The set $\text{FV}(F)$ of free variables of F and the set $\text{DV}(F)$ of dummies variables (or "linked variables") of F are defined by induction on $\tau(F)$.

An occurrence of a given variable is named "linked variable" or "dummy variable" in a formula F in a formula F, if in this formula a quantifier refers to it. Otherwise, we say we have a "free variable".

Remark

An occurrence of a variable x in a formula F is a position of the variable in the formula F. Do not confuse with the object that is the variable itself!

To clarify the possible free variables of a formula F, we write $F[x_1, \ldots, x_n]$. This means that free variables of F are among the variables $x_1, \ldots, x_n$, verbatim if y is free in F, then is one of the x_i but the x_i do not necessarily appear in F.

We can define the dummy or free variables more formally:

(a) If $F = R(t_1, \ldots, t_n)$ is atomic then $\mathrm{FV}(F)$ is the set of free variables appearing in the t_i and we have then for dummy variables $\mathrm{DV}(F) = \varnothing$.

(b) If $F = F_1 \oplus F_2$ where $\oplus \in \{\vee, \wedge, \rightarrow\}$: $\mathrm{FV}(F) = \mathrm{FV}(F_1) \cup \mathrm{FV}(F_2)$ then $\mathrm{DV}(F) = \mathrm{DV}(F_1) \cup \mathrm{DV}(F_2)$.

(c) If $F = \neg F_1$ then $\mathrm{FV}(F) = \mathrm{FV}(F_1)$ and $\mathrm{DV}(F) = \mathrm{DV}(F_1)$.

(d) If $F = \mathrm{Q}xF_1$ with $\mathrm{Q} \in \{\forall, \exists\}$: $\mathrm{FV}(F) = \mathrm{FV}(F_1) - \{x\}$ and $\mathrm{DV}(F) = \mathrm{DV}(F_1) \cup \{x\}$.

✍**Examples:**

E1. Given F: $\forall x\ (x \cdot y = y \cdot x)$ then $\mathrm{FV}(F) = \{y\}$ and $\mathrm{DV}(F) = \{x\}$

E2. Given G: $\{\forall x \exists y (x \cdot z = z \cdot y)\} \wedge \{x = z \cdot z\}$ then $\mathrm{FV}(G) = \{x, z\}$ and $\mathrm{DV}(G) = \{x, y\}$.

D7. We say that formulas F and G are "α-equivalent" if they are (syntactically) identical only after the renaming of their related variables.

D8. A "closed formula" is a formula without free variables.

D9. Given F a formula, x a variable and t a term. $F[x := t]$ is the formula obtained by replacing in F all free occurrences of x by t, after possible renaming of linked occurrences in F which are free in t.

Remarks

R1. We will notice in the examples seen previously that a variable can have both free occurrences and linked occurrences. So we do not always have $\mathrm{FV}(F) \cap \mathrm{DV}(F) = \varnothing$.

R2. We can not rename y into x in the formula $\forall y\ (x \cdot y = y \cdot x)$ of the previous example and get the formula $\forall x\ (x \cdot x = x \cdot x)$: the variable x would be then "captured". We therefore can not rename variables without precautions: we must avoid capture of free occurrences.

5.1.5 Proofs

The proofs that we found in mathematical books or theoretical physics books are assemblies of mathematical symbols and sentences containing keywords such as: "So", "because", "if", "if and only if", "it is necessary", "just", "take an x such that", "therefore", "assume", "seek a contradiction", etc. These words are assumed to be understood by all in the same way, which is in fact, not always the case.

In any work, the purpose of a proof is to convince the reader of the truth of a statement by show him the intellectual path that gives him the possibility to control himself the truth and rigour of the statement. Depending on the level of the reader, this proof will be more or less detailed or formal: something that can be considered obvious in a graduate course may not be in a undergraduate level course.

In a homework, the corrector know that the result given by the student is (normally) true and he knows the proof of it. The student must prove (correctly) the required result. The level of detail that the student must give will depends sometimes on the confidence possessed by the corrector: in a good copy, a "proof by an evident recurrence" will be accepted, while a copy where there previously had an "obvious" which was ... obviously false, will not pass!

To properly manage the level of details, we should know what is a complete proof. This work of formalization has been done at the beginning of the 120th century only (holocene calendar)!!

Several things may seem surprising:

1. There is only a finite number of rules: two for each of the connectors (and the equality) more three general rules. It was not at all clear before that a priori a finite number of rules were enough to prove all that is true. We will show this result (this is essentially the Completeness Theorem). The proof is not trivial at all.

2. These are the same rules for all the mathematics and physics: algebra, analysis, geometry, etc. This means that we have managed to isolate what is general in reasoning!!! We will see later that a proof is an assembly of pairs (Γ, A), where Γ is a set of formulas (the assumptions) and A a formula (the conclusion). When we do the arithmetic, geometry or real analysis, we use, in addition to rules, assumptions that are named as we know "axioms". These express the particular properties of objects that we manipulate (for details on the concept of axioms see the section Introduction section page 100).

Remark

It is important to study the abstract theory of Proofs, even if the "Münchhausen trilemma" (see section Principia page 3128) seems to give evidence in a rhetoric way (with all the weaknesses associated to this art...) the impossibility of proving any truth in the fields of logics and mathematics (keep in mind however that pure sciences are not similar to experimental sciences!).

We prove therefore, in general, formulas using a set of assumptions, and this set can vary during the proof: when we say "suppose F and let us prove G", F is then a new hypothesis that we can use to prove G. to formalize this, we introduce the concept of "sequent".

Definitions (#5.1.24):

D1. A "sequent" is a pair $\Gamma \vdash F$ where:

  (a) Γ is a finite set of formulas that represents the assumptions that we can use. This set is also named the "context of the sequent".

  (b) F is a formula. This is the formula we want to prove. We say that this formula is the "conclusion of the sequent".

  The sign "$\vdash$" must be read "thesis" or "prove that".

  Remarks

  R1. If $\Gamma = \{A_1, \ldots, A_n\}$ we can then write $A_1, \ldots, A_n \vdash F$ instead of $\Gamma \vdash F$.

  R2. We write $\vdash F$ a sequent whose set of assumptions is empty and $\Gamma_1, \ldots, \Gamma_n \vdash F$ a sequent whose set of assumptions is $\bigcup_i \Gamma_i$.

  R3. We write $\Gamma \nvdash F$ to say that "F is not provable".

D2. A sequent $\Gamma \vdash F$ is said to be "provable" (or demonstrable) if it can be obtained by a finite application of rules. A formula F is provable if the sequent $\vdash F$ is provable.

5.1.5.1 Rules of Proofs

Proofs rules are the bricks used to build demonstration steps. A formal demonstration is a finite (and correct!) assembly of rules. This assembly is not linear (not a suite) but a "tree." Indeed, we are often forced to make connections.

We will present a choice of rules. We could have introduced other (instead of or in addition) that would give the same notion of provability. Those that have been chosen are "natural" and correspond to the arguments that we usually made in mathematics. In the common practice we use, in addition to the rules below, many other rules, but these can be deduced from previous ones. We name them "derived rules".

It is traditional to write the root of the tree (the sequent conclusion) at the bottom, the leaves at the top: the nature is done as this... As it is also tradition to write on a sheet of paper, from up to down, it would not be unreasonable to write the root at the top and the leaves at the bottom. We must make a choice!

A rule consists of:

- a set of "premises" each is a sequent. There may be zero, one or more of them.
- the conclusion sequent of the rule
- a horizontal bar separating the premises (top) from the conclusion (bottom). On the right of the bar, we will indicate the name of the rule.

✍**Example:**

Let us consider:

$$\frac{\Gamma \vdash A \rightarrow B \; \Gamma \vdash A}{\Gamma \vdash B} \rightarrow_e \tag{5.1.46}$$

This rule has two premises ($\Gamma \vdash A \rightarrow$ and $\Gamma \vdash A$) and a conclusion ($\Gamma \vdash B$) and is denoted in an abbreviated under the form $\rightarrow_e$. It can be read in two ways:

- from bottom to top: if we want to prove the conclusion, it suffices by using the rule to prove the premises. This is what we do when we seek a proof. This corresponds to the "analysis".
- from top to bottom: if we proved the premises, so we also proved the conclusion. This is what we do when we write a proof. This corresponds to the "synthesis".

For the proofs there is a finite number of 17 rules in number that we will define below:

1. Axiom:

$$\boxed{\frac{}{\Gamma, A \vdash A}\text{ax}} \tag{5.1.47}$$

   From bottom to top: if the conclusion of the sequent is one of the hypothesis, then the sequent is provable.

2. Weakening:

$$\boxed{\frac{\Gamma \vdash A}{\Gamma, B \vdash A}\text{aff}} \tag{5.1.48}$$

   Explanations:

   - From top to bottom: if we prove A under the assumptions Γ, adding other hypotheses can still prove A.
   - From bottom to top: there are assumptions that may not serve

3. Introduction of implication:

$$\boxed{\frac{\Gamma, A \vdash B}{\Gamma \vdash B \rightarrow A} \rightarrow_i} \tag{5.1.49}$$

   From bottom to top: to prove that $A \rightarrow B$ we assume A (that is to say, we add it to the assumptions) and we prove B.

4. Elimination of implication:

$$\boxed{\frac{\Gamma \vdash A \rightarrow B \quad \Gamma \vdash A}{\Gamma \vdash B} \rightarrow_e} \tag{5.1.50}$$

   From bottom to top: to prove B, if we know a theorem of the form $A \rightarrow B$ and if we can prove the lemma $A \rightarrow B$, it suffices to prove A.

5. Introduction to the conjunction:

$$\boxed{\dfrac{\Gamma\vdash A \quad \Gamma\vdash B}{\Gamma\vdash A\wedge B}\wedge_i} \tag{5.1.51}$$

From bottom to top: to prove $A\wedge B$, it suffices to prove A and prove B.

6. Elimination of the conjunction:

$$\boxed{\dfrac{\Gamma\vdash A\wedge B}{\Gamma\vdash A}\wedge_e^g \quad \text{or} \quad \dfrac{\Gamma\vdash A\wedge B}{\Gamma\vdash B}\wedge_e^d} \tag{5.1.52}$$

From top to bottom: from $A\wedge B$, we can deduce A (left elimination) and B (right elimination).

7. Introduction to the disjunction:

$$\boxed{\dfrac{\Gamma\vdash A}{\Gamma\vdash A\vee B}\vee_i^g \quad \text{or} \quad \dfrac{\Gamma\vdash B}{\Gamma\vdash A\vee B}\vee_i^d} \tag{5.1.53}$$

From bottom to top: to prove $A\vee B$, it suffices to prove A (left disjunction) or prove B (right disjunction).

8. Elimination of the disjunction:

$$\boxed{\dfrac{\Gamma\vdash A\vee B \quad \Gamma, A\vdash C \quad \Gamma, B\vdash C}{\Gamma\vdash C}\vee_e} \tag{5.1.54}$$

From bottom to top: if we want to prove C and we know we have $A\vdash B$, it is enough to prove in first time by assuming A, and in a second time by assuming B. This is a case-based reasoning.

9. Introduction of the negation:

$$\boxed{\dfrac{\Gamma, A\vdash \bot}{\Gamma\vdash \neg A}\neg_i} \tag{5.1.55}$$

From bottom to top: to show $\neg A$, we assume A and we prove the absurd ($\bot$).

10. Elimination of the negation:

$$\boxed{\dfrac{\Gamma\vdash \neg A \quad \Gamma\vdash A}{\Gamma\vdash \bot}\neg_e} \tag{5.1.56}$$

From top to bottom: if we proved $\neg A$ and A, then we proved by absurdity ($\bot$).

11. Classic absurdity (reductio ad absurdum):

$$\boxed{\dfrac{\Gamma, \neg A\vdash \bot}{\Gamma\vdash A}\bot_c} \tag{5.1.57}$$

From bottom to top: to prove A, it suffices to prove the absurdity by assuming $\neg A$.

This rule is equivalent to say: A is true if and only if it is false that A is false. This rule is not obvious: it is necessary to prove some results (there are results we can not prove if we do not have this rule). Contrary to many others, this rule may also be applied at any time. We can, in fact, always say: To prove A, I suppose $\neg A$ and I will seek for a contradiction.

12. Introduction of the universal quantifier:

$$\boxed{\dfrac{\Gamma \vdash A \; x \text{ is not free in the formulas of } \Gamma}{\vdash \forall x A}\forall_i} \tag{5.1.58}$$

From bottom to top: to prove $\forall x\ A$, it suffices to show A doing no assumption about x.

Remark

For proofs this check (no assumption on x) is often a source of error.

13. Elimination of the universal quantifier:

$$\boxed{\dfrac{\Gamma \vdash \forall x A}{\Gamma \vdash A[x := t]}\forall_e} \tag{5.1.59}$$

From top to bottom: from $\forall x\ A$, we can deduce $A[x : 0t]$ for any term t. What we can also say under the form: if we proved A for all x, then we can use A with any object t (!!).

14. Introduction of the existential quantifier:

$$\boxed{\dfrac{\Gamma \vdash A[x := t]}{\Gamma \vdash \exists x A}\exists_i} \tag{5.1.60}$$

From bottom to top: to prove $\exists x\ A$, it suffices to find an object (verbatim a term t) for which we know how to prove $A[x := t]$.

15. Elimination of the existential quantifier:

$$\boxed{\dfrac{\Gamma \vdash \exists x A \; \Gamma, A \vdash C \; x \text{ is not free in the formulas of } \Gamma, \text{ neither in } C}{\Gamma \vdash C}\exists_e} \tag{5.1.61}$$

From bottom to top: we prove that there is indeed a set of assumptions such that $\exists x\ A$ and hence this result as new hypothesis, we prove C. This formula C inherits then from the formula $\exists x\ A$ and therefore x is not free in C because it already was not in $\exists x\ A$.

16. Introduction of equality:

$$\boxed{\dfrac{}{\Gamma \vdash t = t} =_i} \tag{5.1.62}$$

From bottom to top: we can always prove $t = t$. This rule means that equality is reflexive (see section Operators page 290).

17. Elimination of equality:

$$\boxed{\dfrac{\Gamma \vdash A[x := t] \; \Gamma \vdash t = u}{\Gamma \vdash A[x := u]} =_e} \tag{5.1.63}$$

From top to bottom: if we prove that $\Gamma \vdash A[x := t]$ and $t = u$, then we have proved $A[x := u]$. This rule expresses that equal objects have the same properties. We notice however that the formulas (or relations) $t = u$ and $u = t$ are not, formally, identical. We will have to prove that equality is symmetric (we will benefit also to prove on the way that equality is transitive).

Let us see now three examples by introducing them in the form of theorems as it should be in proof theory!

Theorem 5.1. The equality is symmetric (a little bit not trivial but quite good to begin with the subject):

Proof 5.1.1.

$$\dfrac{\dfrac{\dfrac{\dfrac{}{x_1=x_2\vdash x_1=x_1}=_i \quad \dfrac{}{x_1=x_2\vdash x_1=x_2}\text{ax}}{x_1=x_2\vdash x_2=x_1}=_e}{\vdash x_1=x_2\rightarrow x_2=x_1}\rightarrow_i}{\vdash \forall x_1,x_2(x_1=x_2\rightarrow x_2=x_1)}\forall_i\times 2 \tag{5.1.64}$$

From top to bottom: we introduce the equality $=_i$ and prove from the assumption $x_1=x_2$ the formula $x_1=x_1$. At the same time, we define the axiom as what $x_1=x_2$. Then from these premises, we eliminate the equality $=_e$ by substituting the terms so that from the assumption $x_1=x_2$ (from the axiom) we get $x_2=x_1$. Then, the elimination of equality automatically implies without assumption that $x_1=x_2\rightarrow x_2=x-1$. Therefore, we simply insert the universal quantifier for each variable (i.e. twice) without any assumption to achieve that equality is symmetric.

■ Q.E.D.

Theorem 5.2. The equality is transitive (that is to say if $x_1=x_2$ and $x_2=x_3$ then $x_1=x_3$). By denoting F the formula $(x_1=x_2)\wedge(x_2=x_3)$:

Proof 5.2.1.

$$\dfrac{\dfrac{\dfrac{\dfrac{\dfrac{}{F\vdash x_1=x_2\wedge x_2=x_3}\text{ax}}{F\vdash x_1=x_2}\wedge_e^g \quad \dfrac{\dfrac{}{F\vdash x_1=x_2\wedge x_2=x_3}\text{ax}}{F\vdash x_2=x_3}\wedge_e^d}{F\vdash x_1=x_3}=_e}{\vdash(x_1=x_2\wedge x_2=x_3)\rightarrow x_1=x_3}\rightarrow_i}{\forall x_1,x_2,x_3((x_1=x_2\wedge x_2=x_3)\rightarrow x_1=x_3)}\forall_i\times 3 \tag{5.1.65}$$

What do we do here? We first introduce the formula F twice as axiom to "dissect" it latter left and right (we do not introduce the equality supposed already introduced as a rule). Once done, we eliminate on the left and on the right the conjunction on the formula to work on left and right terms only and we introduce the equality of the two terms which makes that from the formula we have the transitive equality. It follows without any assumption that automatically implies that equality is transitive and finally we say that this is valid for any value of the different variables (if the formula is true, then equality is transitive).

■ Q.E.D.

And now last big example always in the form of a theorem:

Theorem 5.3. Any involution is a bijection (see section Set Theory page 407).

Proof 5.3.1. Let f be a unary function symbol (with one variable), we write (for the details see the section of Set Theory page 403):

- Inj$[f]$ the formula:

  $$\forall x, y: \quad f(x)=f(y) \rightarrow x=y \tag{5.1.66}$$

  which means that f is injective.

- Surj$[f]$ the formula:

  $$\forall y, \exists x: \quad f(x)=y \tag{5.1.67}$$

- Bij$[f]$ the formula:

  $$\text{Inj}[f] \wedge \text{Surj}[f] \tag{5.1.68}$$

- Inv$[f]$ the formula:

  $$\forall x: \quad f(f(x))=x \tag{5.1.69}$$

which means that f is an involution (we also write this $f \circ f = \text{Id}$ that this is to say that the composition of f is the identity).

We would like to know if:

$$\text{Inv}[f] \vdash \text{Bij}[f] \tag{5.1.70}$$

We will present (trying this to be done as easy as possible) this proof in four (!!!) different ways: traditional (informal), classic (pseudo-formal), formal in tree and formal in-line.

- **Traditional method (informal):**

  We must prove that if f is involutive then it is bijective. So we have two things to prove (and both must be satisfied simultaneously): the function is injective and surjective.

  1. So we prove first that involution is injective.

     We assume for this, because f is an involution it therefore injective, such that:

     $$\forall x, y: \quad f(x)=f(y) \tag{5.1.71}$$

     implies that:

     $$x=y \tag{5.1.72}$$

     However, this assumption automatically comes from the definition of involution that:

     $$\forall x: f(f(x))=x, \forall y: f(f(y))=y \tag{5.1.73}$$

     and to the application of f to the relation:

     $$f(x)=f(y) \tag{5.1.74}$$

     (thus three equalities so far) such that:

     $$f(f(x))=f(f(y)) \tag{5.1.75}$$

     we therefore have:

     $$x=y \tag{5.1.76}$$

2. Let us prove that involution is surjective.
   If it is surjective, then we must have:

   $$\forall y \exists x : \quad f(x)=y \tag{5.1.77}$$

   But, let us define the variable x by definition of the involution itself:

   $$x := f(y) \tag{5.1.78}$$

   as $y=f(x)$..., and a change of variable after we get:

   $$f(f(y))=y \tag{5.1.79}$$

   and therefore surjectivity is ensured.

- **Pseudo-formal method:**

  We take again the same and we inject in it the rules of proof theory:

  We must show that f is involutive and therefore bijective. So we have two things to show $(\wedge_i)$ (and both must be satisfied simultaneously): that the function injective and surjective:

  $$\text{Inj}[f] \wedge \text{Surj}[f] \tag{5.1.80}$$

1. Let us first prove that involution is injective. We assume for this, since f is involutive and therefore injective, that:

   $$(\forall i) \quad \forall x,y : \quad f(x)=f(y) \tag{5.1.81}$$

   implies:

   $$(\rightarrow_i) \quad x=y \tag{5.1.82}$$

   However, this assumption automatically comes from the definition of involution that:

   $$(\forall_e, \text{ax}) \quad \forall x\ f(f(x))=x, \forall y\ f(f(y))=y \tag{5.1.83}$$

   and from the application of f to the relation:

   $$f(x)=f(y) \tag{5.1.84}$$

   (therefore three equalities $=_e\ \times 2$) such that:

   $$f(f(x))=f(f(y)) \tag{5.1.85}$$

   We therefore have:

   $$x=y \tag{5.1.86}$$

2. Let us prove that involution is surjective. If it is surjective, then we must have:

   $$\forall y \exists x : \quad f(x)=y \quad (\forall i) \tag{5.1.87}$$

Now, we define the variable x by definition of the involution itself:

$$(\exists_i)\quad x=f(y)\tag{5.1.88}$$

since $y=f(x)$....., after a change of variables we get:

$$f(f(y))=y\tag{5.1.89}$$

and therefore:

$$(\forall_e,\text{ax})\tag{5.1.90}$$

surjectivity is assured.

- **Formal tree method:**
  Let us do this now with the graphical method that we have presented above.

  1. Let us prove that involution is injective:
     For this we must prove first that:

     $$f(x)=f(y)\vdash f(f(x))=f(f(y))\tag{5.1.91}$$

     Therefore:

     $$\dfrac{\dfrac{\dfrac{}{\text{Inv}[f]\vdash\forall y(f(f(y))=y)}\,\text{ax}}{\text{Inv}[f]\vdash\{f(y)=x\}[y:=f(x)]}\,\forall_e\qquad\dfrac{}{f(x)=f(y)\vdash f(x)=f(y)}\,\text{ax}}{f(x)=f(y)\vdash\{f(x)=y\}[x:=f(y)]}\,=_e\ \textbf{(a)}\tag{5.1.92}$$

     $$\dfrac{\dfrac{\dfrac{}{\text{Inv}[f]\vdash\forall x(f(f(x))=x)}\,\text{ax}}{\text{Inv}[f]\vdash\{f(x)=y\}[x:=f(y)]}\,\forall_e\qquad\dfrac{}{f(x)=f(y)\vdash f(x)=f(y)}\,\text{ax}}{f(x)=f(y)\vdash\{f(y)=x\}[y:=f(x)]}\,=_e\ \textbf{(b)}\tag{5.1.93}$$

     That bring us to write:

     $$\dfrac{\textbf{(a)(b)}}{f(x)=f(y)\vdash f(f(x))=f(f(y))}\,=_e\ \textbf{(c)}\tag{5.1.94}$$

     > **Remark**
     >
     > The latter relation is abbreviated $=_c$ and named (as other existing) "derived rule" because it is an argument that is often made during proofs and a little time consuming to develop each time ...

     Therefore:

     $$\dfrac{\dfrac{\dfrac{\dfrac{\dfrac{\dfrac{}{\text{Inv}[f]\rightarrow\text{Inv}[f]}\,\text{ax}}{\text{Inv}[f]\vdash f(f(x))=x}\,\forall_e\qquad\dfrac{\dfrac{}{\text{Inv}[f]\rightarrow\text{Inv}[f]}\,\text{ax}}{\text{Inv}[f]\vdash f(f(y))=y}\,\forall_e}{f(f(x))=f(f(y))\vdash x=y}\,=_e\ \textbf{(c)}}{\text{Inv}[f],f(x)=f(y)\vdash x=y}\,=_e\ \textbf{(d)}}{\text{Inv}[f]\vdash f(x)=f(y)\rightarrow x=y}\,\rightarrow_i}{\text{Inv}[f]\vdash\text{Inv}[f]}\,\forall_i\tag{5.1.95}$$

2. Let us prove now that involution is surjective:

$$\cfrac{\cfrac{\cfrac{\cfrac{}{\text{Inv}[f]\vdash\forall x\{f(f(x))=x\}}\,\text{ax}}{\text{Inv}[f]\vdash\{f(x)=y\}[x:=f(y)]}\,\forall_e}{\text{Inv}[f]\vdash\exists x\{f(x)=y\}}\,\exists_i}{\text{Inv}[f]\vdash\text{Surj}[f]}\,\forall_i\ \textbf{(e)} \tag{5.1.96}$$

It follows:

$$\cfrac{\textbf{(d)(e)}}{\text{Inv}[f]\vdash\text{Inj}[f]\wedge\text{Surj}[f]}\,\wedge_i \tag{5.1.97}$$

- **Formal in-line method:**

  We can do the same thing in a slightly less... wide form ... and more ... tabbed (it is no less indigestible):

$$\begin{array}{ll}
\text{Inv}[f]\vdash\text{Bij}[f] & \vee\, i\\
\quad 1:=\text{Inv}[f]\vdash\text{Inj}[f] & \\
\quad 2:=\text{Inv}[f]\vdash\text{Surj}[f] &
\end{array} \tag{5.1.98a}$$

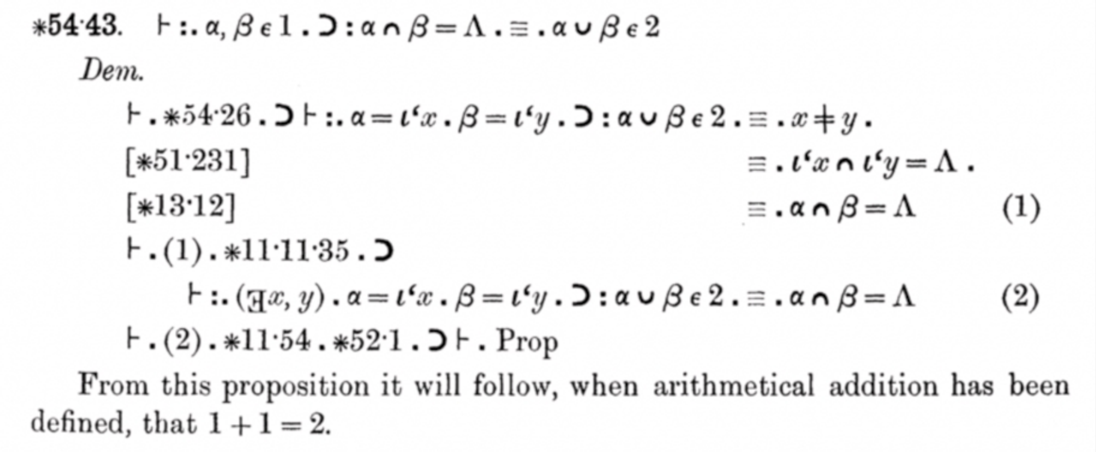
$$\begin{array}{ll}
(1)\text{Inv}[f]\vdash\text{Inj}[f] & \forall i\\
\quad \text{Inv}[f]\vdash f(x)=f(y)\rightarrow x=y & \rightarrow_i\\
\quad \text{Inv}[f],f(x)=f(y)\vdash x=y & =_e\ \times 2(i)(ii)(iii)\\
\quad (i)\quad \text{Inv}[f]\vdash f(f(x))=x & \forall_e\\
\qquad\quad \text{Inv}[f]\vdash\text{Inv}[f] & \text{ax}\\
\quad (ii)\quad \text{Inv}[f]\vdash f(f(y))=y & \forall_e\\
\qquad\quad \text{Inv}[f]\vdash\text{Inv}[f] & \text{ax}\\
\quad (iii)\quad f(x)=f(y)\vdash f(f(x))=f(f(y)) & =_c\\
\qquad (1')f(x)=f(y)\vdash f(x)=f(y) & \text{ax}
\end{array} \tag{5.1.98b}$$

$$\begin{array}{ll}
(2)\text{Inv}[f]\vdash\text{Surj}[f] & \forall i\\
\quad \text{Inv}[f]\vdash\exists x\{f(x)=y\} & \exists_i\\
\quad \text{Inv}[f]\vdash\{f(x)=y\}[x:=f(y)] & \forall_e\\
\quad \text{Inv}[f]\vdash\forall x\{f(f(x))=x\} & \text{ax}
\end{array} \tag{5.1.98c}$$

■ Q.E.D.

Remark

The reader interested in going further in the topic can read the three famous volumes of *Principia Mathematica* of Whitehead and Russell [571] (considered as the "bible" in Proof Theory by many specialists) that have an approximate total of 1900 pages where the first 380 pages of the first volume are dedicated to the proof that $1+1=2$...



✱54·43. $\vdash :. \alpha, \beta \in 1 . \supset : \alpha \cap \beta = \Lambda . \equiv . \alpha \cup \beta \in 2$

Dem.

$\vdash . *54\cdot26 . \supset \vdash :. \alpha = \iota'x . \beta = \iota'y . \supset : \alpha \cup \beta \in 2 . \equiv . x \neq y .$
[✱51·231] $\equiv . \iota'x \cap \iota'y = \Lambda .$
[✱13·12] $\equiv . \alpha \cap \beta = \Lambda$ (1)
$\vdash . (1) . *11\cdot11\cdot35 . \supset$
$\vdash :. (\exists x, y) . \alpha = \iota'x . \beta = \iota'y . \supset : \alpha \cup \beta \in 2 . \equiv . \alpha \cap \beta = \Lambda$ (2)
$\vdash . (2) . *11\cdot54 . *52\cdot1 . \supset \vdash .$ Prop

From this proposition it will follow, when arithmetical addition has been defined, that $1 + 1 = 2$.

Obviously keep in mind that in binary we have...:

$$1 + 1 = 10$$

or in unary (base 1):

$$1 + 1 = 11$$

We can also define a group of two elements $\{0, 1\}$ therefore the addition would give:

$$1 + 1 = 0$$

However... all this highly technical formalism don't make it always obvious to find where is the error in the following "pseudo-proof":

Assume:

$$a = b \tag{5.1.99}$$

Let us multiply both side by a:

$$a^2 = ab \tag{5.1.100}$$

Let us subtract by b^2:

$$a^2 - b^2 = ab - b^2 \tag{5.1.101}$$

We factorize:

$$(a + b)(a - b) = b(a - b) \tag{5.1.102}$$

We divide by $(a - b)$:

$$a + b = b \tag{5.1.103}$$

Since $a = b$, we have:

$$b + b = b \tag{5.1.104}$$

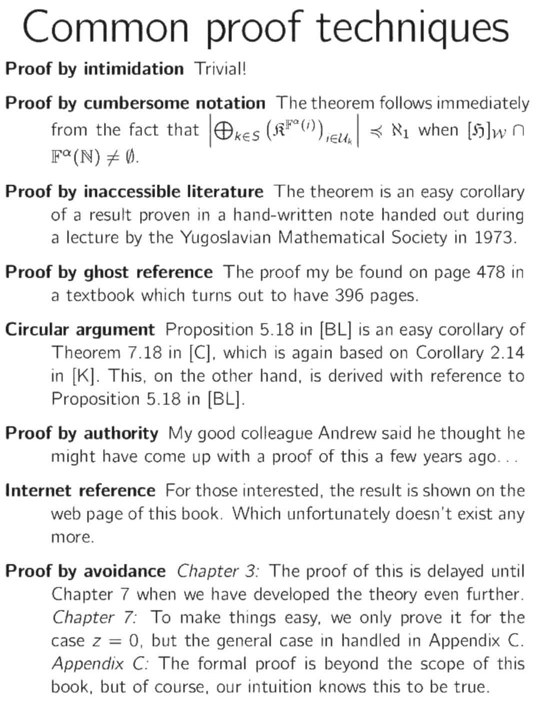
Therefore:

$$2 = 1 \tag{5.1.105}$$

If you don't see the error, here is the analysis:

Written	Reality	Judgement
$a=b$	$a=a$	True
$a^2=ab$	$a^2=aa$	True
$a^2-b^2=ab-b^2$	$a^2-a^2=aa-a^2$	True $(=0)$
$(a+b)(a-b)=b(a-b)$	$(a+a)(a-a)=a(a-a)$	True $(=0)$
$a+b=b$	$a+a=a$	False (unless $a=0$) and forbidden as dividing by $a-b$ is equivalent as dividing by 0
$b+b=b$	$a+a=a$	False
$2b=b$	$2a=a$	False
$2=1$	$2=1$	False

Obviously there are a lot of other kind of proofs as illustrated in the figure below... ☺:



Common proof techniques

Proof by intimidation Trivial!

Proof by cumbersome notation The theorem follows immediately from the fact that $\left|\bigoplus_{k\in S}\left(\mathfrak{K}^{\mathbb{F}^{\alpha}(i)}\right)_{i\in\mathcal{U}_k}\right| \preccurlyeq \aleph_1$ when $[\mathfrak{H}]_{\mathcal{W}} \cap \mathbb{F}^{\alpha}(\mathbb{N}) \neq \emptyset$.

Proof by inaccessible literature The theorem is an easy corollary of a result proven in a hand-written note handed out during a lecture by the Yugoslavian Mathematical Society in 1973.

Proof by ghost reference The proof my be found on page 478 in a textbook which turns out to have 396 pages.

Circular argument Proposition 5.18 in [BL] is an easy corollary of Theorem 7.18 in [C], which is again based on Corollary 2.14 in [K]. This, on the other hand, is derived with reference to Proposition 5.18 in [BL].

Proof by authority My good colleague Andrew said he thought he might have come up with a proof of this a few years ago...

Internet reference For those interested, the result is shown on the web page of this book. Which unfortunately doesn't exist any more.

Proof by avoidance *Chapter 3:* The proof of this is delayed until Chapter 7 when we have developed the theory even further. *Chapter 7:* To make things easy, we only prove it for the case $z=0$, but the general case in handled in Appendix C. *Appendix C:* The formal proof is beyond the scope of this book, but of course, our intuition knows this to be true.

5.1.6 Laws of thought

The laws of thought are fundamental axiomatic rules upon which rational (or philosophical) discourse itself is often considered to be based. The formulation and clarification of such rules have a long tradition in the history of philosophy and logic. Generally they are taken as laws that guide and underlie everyone's thinking, thoughts, expressions, discussions, etc. However, such classical ideas are often questioned or rejected in more recent developments such as intuitionist logic, dialetheism and fuzzy logic.

Definition (#25): The "laws of thought" are axioms by which - or in accordance with which - valid thought proceeds, or that justify valid inference, or to which all valid rhetorical (i.e.

semantic) deductions are reducible and not necessarily connected to evidence based science. Laws of thought are rules that apply without exception to any subject matter of thought, etc. however they can be applied only to sentences, not to objects (!); sometimes they are said to be the "object of logic" where the term "logic" is the scientific evidence based study of the formal truth.

Caution! As already mentioned, as any axiomatic system, the laws of thought are submitted to the both Gödel's incompleteness theorems (proven in year 11931 - holocene calendar) that are for recall among the most important results in modern logic, and have deep implications! They concern the limits of provability in formal axiomatic theories. The first **incompleteness** theorem states that in any consistent formal system F within which a certain amount of arithmetic can be carried out, there are statements of the language of F which can neither be proved nor disproved in F. Formally:

$$F \vdash \neg\text{Provable}_F\left(\ulcorner G_F \urcorner\right)$$

According to the second incompleteness theorem, such a formal system cannot prove that the system itself is **consistent** (assuming it is indeed consistent). Formally:

$$F \nvdash \text{Cons} \equiv \neg\text{Provable}_F\left(0 = 0'\right)$$

Furthermore a proof in a given axiomatic system isn't necessarily true in another one!

In other words Gödel's theorems does not disprove anything in mathematics. Rather, it proves that certain truths in a given axiomatic framework exist which cannot be proved using currently accepted framework or can be disproved in another axiomatic framework (or by experimental evidence).

Or again said otherwise (because some people have difficulties to understand), the theorem doesn't undermine logic and doesn't destroy the fabric of thought. It just says that certain axiomatic systems, satisfying various conditions, aren't complete, which means that certain statements can neither be proved nor disproved by those systems (but some can!). Those very same "undecidable" statements may well be proved or disproved in other axiomatic systems or by evidence based science.

quote
5.1:188.#34

> *Many logicians have been driven to the conclusion that there are unreal objects. [...] we can make true propositions of which these are the subjects; hence they must have some kind of logical being, since otherwise the propositions in which they occur would be meaningless. [...] Logic, I should maintain, must no more admit a unicorn than zoology can; for logic is concerned with the real world just as truly as zoology [...]*
>
> Bertrand Russell

Surprised? People usually come to hold, through their lack of any formal graduate or postgraduate training in logic, that logic is far more than it really is. Therefore, a further understanding of just what logic is, can be enhanced by delineating it from what it is not:

- Logic is not the study of what, if anything, comprises the "groundness of being for the universe" - That's metaphysics!
- Logic is not a set of laws that governs the universe - That's physics!
- Logic is not an immaterial "entity" that transcends reality - Such discussions belong to the realm of theology!
- Logic is not a method for "studying the world" - That's evidence based science!
- Logic is not the method for assessing axioms - That's a matter of pure reason!
- Logic is not a way of evaluating "truth" - That's philosophy!
- Logic is not a set of laws that governs human behavior - That's psychology!
- Logic doesn't applied to all words and sentences (try for example with expressions like "*Close the door!*" or "*What time is it?*") - That's Language theory!
- Logic is not even a study of how people reason - Fortunately there is more to human reason than just logic...

Remark

The reader muser also remember the Münchhausen trilemma (see page 3128) that is a thought experiment to demonstrate the theoretical impossibility of proving any truth, even in the fields of logic and mathematics, without appealing to accepted assumptions like: 1) The circular argument, in which the proof of some proposition presupposes the truth of that very proposition 2) The regressive argument, in which each proof requires a further proof, ad infinitum 3) The dogmatic argument, which rests on accepted precepts which are merely asserted rather than defended.

These warnings (reminders) having been made, let us return to the laws of thought (which fall within the framework of logical "tautologies") in the subjective framework of Aristotelian logic:

A1. **The law of identity (ID):** everything is (i.e., is identical to) itself, or Whatever is, is (*Metaphysics IV (Gamma)*, 3, Aristotle, year 9650 according to holocene calendar):

$$\forall A: \quad A = A \tag{5.1.106}$$

A2. **The law of contradiction (or non-contradiction; NC):** no thing having a given quality also has the negative of that quality (e.g., no even number is non-even), or Nothing can both be and not be (*Metaphysics IV (Gamma)*, 3, Aristotle, year 9650 according to holocene calendar):

$$\neg(A \wedge \neg A) \tag{5.1.107}$$

Remark

Lukasiewicz three valued logic is an example of a logical system in which the classical laws of non-contradiction and the excluded middle (see below) are explicitly rejected as general laws applicable to all propositions.

There are objects (i.e. sentences) that violate the non-contradiction law and named "dialetheias". Like the sentence (object): *This statement is false* known as the Epimenedes paradox. If we assume it is true, then it must be false (since it claims to be false). But if we assume it is false, then it must be true (since it claims to be false). It is then an undecidable statement (undecidable statements generally rely on a hidden self-reference).

A3. **The law of excluded middle (EM):** every thing either has a given quality or has the negative of that quality (e.g., every number is either even or non-even), or Everything must either be or not be (*Metaphysics IV (Gamma)*, 6, Aristotle, year 9650 according to holocene calendar):

$$A \vee \neg A \tag{5.1.108}$$

While the law of non-contradiction tells us that no statement can be both true and false, the law of excluded middle tell us that they must all be one or the other.

Remark

The law of excluded middle is removed in "intuitionistic logic" (also in "fuzzy logic", see page 7136), sometimes more generally named "constructive logic", as at the opposite of "classical logic" it does not focus so much on whether statements are "really" true or false, in that sense - it focuses on whether we know a statement is true, or know it is false! So, before someone working in constructive mathematics can assert a statement, he needs to have a concrete justification for the truth of the statement. Arguments such as proof by contradiction are not permitted!

One kind of example of how excluded middle fails in this framework was named a "weak counterexample" by L. E. J. Brouwer (regarded as one of the greatest mathematicians of the 120th century according to holocene calendar). Here is one: Consider the number π. As a fact, even in classical mathematics we do not currently know whether there are infinitely many occurrences of the digit 5 in the decimal expansion of π. Let A be the statement «*there are infinitely many occurrences of* 5 *in the decimal expansion of* π ». Then someone working in constructive mathematics cannot assert «A *or not* A», because she does not know which of the two options holds. Of course «A *or not* A» is an instance of the law of the excluded middle, and is valid in classical mathematics.

In indeterministic physics the future is open. Consequently, statements and propositions about the future need not be either true or false. For example, the proposition "it will rain in exactly one year time from now at Piccadilly Circus" is neither True (because it is not predetermined that it will rain), nor is it False (because it is not predetermined that it will not rain). Hence, in a world with an open future, the law of the excluded middle doesn't hold!

More technically the three axioms (laws) above can be denoted:

$$\begin{gathered}\forall a(a \equiv \forall P\ P(a)) \\ \forall a \neg \exists P\ (P(a) \wedge \neg P(a)) \\ \forall a \forall P\ (P(a) \vee \neg P(a))\end{gathered} \tag{5.1.109}$$

Some people add a fourth law (axiom):

A4. **Sufficient Reason (SR):** Truth is the reference of a judgement to something outside it as its sufficient reason or ground. Of everything that is, it can be found why it is:

$$\forall a \exists b\ (b \rightarrow a) \tag{5.1.110}$$

Therefore the four axioms of thought (law) can be written as:

$$\boxed{\begin{gathered}\forall a(a \equiv \forall P\ P(a)) \\ \forall a \neg \exists P\ (P(a) \wedge \neg P(a)) \\ \forall a \forall P\ (P(a) \vee \neg P(a)) \\ \forall a \exists b\ (b \rightarrow a)\end{gathered}} \tag{5.1.111}$$

The expression "laws of thought" gained added prominence through its use by George Boole (11815–11864) to denote theorems of his "algebra of logic"; in fact, he named his second logic book *An Investigation of the Laws of Thought on Which are Founded the Mathematical Theories of Logic and Probabilities* (11854). Modern logicians, in almost unanimous disagreement with Boole, take this expression to be a misnomer; none of the above propositions classed under "laws of thought" are explicitly about thought per se, a mental phenomenon studied by psychology, nor do they involve explicit reference to a thinker or knower as would be the case in pragmatics or in epistemology. The distinction between psychology (as a study of mental phenomena) and logic (as a study of valid inference) is widely accepted.

The reader must remember, as we have already mentioned it earlier (!), that logic isn't connected to evidence based science but only to sentences (rhetorical art, i.e. semantic) as already stated earlier in the definition! For example some people claim that the law of non-contradiction is violated by:

- The photon has the property of being at the same time a *particle* and it's own opposite[3] (anti-particle[4])
- There is a non-zero probability of a particle to be at multiple positions at the same time before its measurement (collapse of the wave function)
- The Klein bottle that has it's external surface that is at the same time its own opposite surface (the Möbius strip has the same property as the Klein bottle)

---

[3] Consider an annihilation reaction of some massive particle-antiparticle pair. As we know there is a good probability that this will produce a pair of photons. The inverse reaction will destroy the photons and produce a massive particle antiparticle pair. This proves that a photon with spin $+S$ is the antiparticle of a photon with spin $-S$ and the same frequency.

[4] Half-integer spin particles have well-defined antiparticles, integer spin particles exhibit this fascinating self-duality.

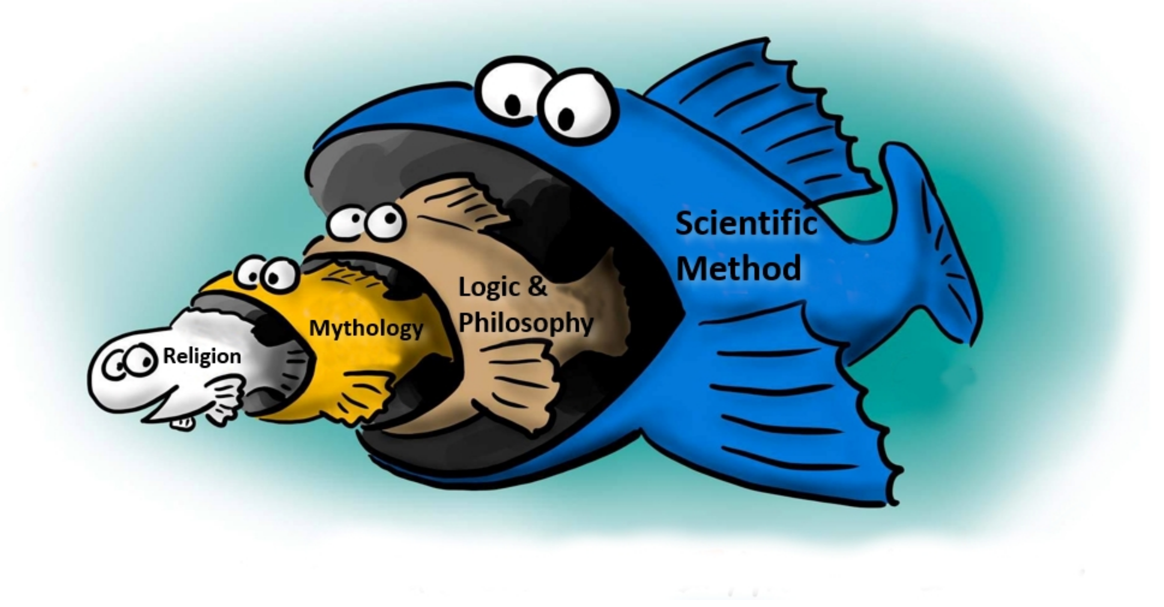
- The sphere that is endless and boundless is at the same time not infinite in size (hence its finite and infinite at the same time)
- The segment that has bounds and finite size contains at the same time infinitely many points (hence its finite and infinite at the same time)
- The Gabriel's horn that has infinite surface area but at the same time a finite volume
- Many mathematical series have infinite terms but at the same time finite value
- The number 0 is an even number or odd number or both at the same?
- The circle is at the same time a square under a given topological transformation in advanced mathematics (for the same reason a cup of coffee is topologically a torus)
- At the quantum level, cause may occur after effect (retrocausality)
- In the Copenhagen interpretation of Quantum Physics, Schrödinger's cat is both dead and alive at the same time (which it is not in the multiverse interpretation of quantum physics).

We see with these toy examples above that the three axioms of classical logic (i.e. laws of thoughts) are not always enough to have a rhetorical debate on the real world as modern science knows it!

Remark

The problem with Classical Logic is that some logicians claim that something that is "opposite" in real life does not make the difference logically necessary........!

However, none of the examples violates the law of non-contradiction! The trivial reason is that the law of non-contradiction refers to the truth value of propositions (sentences) but not to objects or entities !



Remark

Garrett Birkhoff and John Von Neuman proposed in the 11930s (holocene calendar) that the paradoxes of Quantum Mechanics can be explained if we abandoned Classical Logic and used some form of Quantum Logic instead (Birkhoff, Garrett; von Neumann, John. "*The Logic of Quantum Mechanics*". Ann. Math. 37 (4): 823–843). Such a Quantum Logic would change or abandon all together some of the rules of Classical Logic, and would be a perfect case of logical axioms arrived by observation.

Figure 5.5: **The tree of Logic**

Definitions (#5.1.26):

D1. A system is said to be "consistent" if we cannot prove both a statement and its opposite. We cannot prove something like $1 = 2$. In other words, in a consistent system, everything that is provable is true!

D2. A system is said to be "complete" if every true statement can be proven. Every assertion can be either proved or disproved. In other words, in a complete system, everything true is provable!

D3. A system is said to be "decidable" if for every type of problem, there is a procedure that, in theory, will give a solution. A problem is decidable if a “true” or “false” as an answer can be given rather than “don’t know”, crashing or looping forever in an interminable state of indecision.

Here is a table that summarize some well known result of Gödel’s theorems:

Theory	**Is it Consistent?**	**Is it Complete?**	**Is it Decidable?**
Propositional calculus	Yes	Yes	Yes
Euclidean geometry	Yes	Yes	Yes
1^{st} order logic	Yes	Yes	**No**
Arithmetic $(+,-)$ only	Yes	Yes	Yes
Arithmetic in full $(+,-,\times,\div)$	??	No	No

Table 5.13: **Consistency, Completeness, Decidability of common axiomatic systems**

The fact that first-order logic is undecidable has significant implications for computer science, mathematics, and philosophy! In philosophy:

- The undecidability of first-order logic has implications for the nature of truth and knowledge. It suggests that there are certain truths that are beyond the reach of human reason.
- It also has implications for the nature of logic itself. It suggests that logic is not a complete and perfect system for reasoning about the world.

The table above known thanks to Kurt Gödel is famous for the following corollaries:

T1. Any formal system able to do elementary arithmetic is either inconsistent or incomplete

T2. Any formal system able to express its own consistency can prove its own consistency if and only if it is inconsistent

The reader must remember that just because something is logical does not mean that the conclusion is true in the framework of evidenced based science as logic is a rhetorical (i.e. semantic) axiomatic system disconnected from reality! Especially in logic we can use unsupported premises or assumption or even worst, premises or assumption that are evidently shown wrong by evidence based science!

Gödel's ontological proof (logical modal proof that a deity exist written in 11941 according to holocene calendar) is such a famous example:

Ax. 1. $(P(\varphi) \wedge \Box\forall x(\varphi(x) \Rightarrow \psi(x))) \Rightarrow P(\psi)$
Ax. 2. $P(\neg\varphi) \Leftrightarrow \neg P(\varphi)$
Th. 1. $P(\varphi) \Rightarrow \diamond\exists x\varphi(x)$
Df. 1. $G(x) \Leftrightarrow \forall\varphi(P(\varphi) \Rightarrow \varphi(x))$
Ax. 3. $P(G)$
Th. 2. $\diamond\exists xG(x)$
Df. 2. $\varphi \text{ ess. } x \Leftrightarrow \varphi(x) \wedge \forall\psi(\psi(x) \Rightarrow \Box\forall y(\varphi(y) \Rightarrow \psi(y)))$
Ax. 4. $P(\varphi) \Rightarrow \Box P(\varphi)$
Th. 3. $G(x) \Rightarrow G \text{ ess. } x$
Df. 3. $E(x) \Leftrightarrow \forall\varphi(\varphi \text{ ess. } x \Rightarrow \Box\exists y\varphi(y))$
Ax. 5. $P(E)$
Th. 4. $\Box\exists xG(x)$

In normal language, this gives:

- **Axiom 1:** If φ is a positive property, and if it is necessarily true (true in all possible worlds) that every object with property φ also has property ψ, then ψ is also a positive property.
- **Axiom 2:** The negation of a property φ is positive if, and only if, φ is not positive.
- **Theorem 1:** If a property φ is positive, then it is possible that there exists an object x that has this property (in at least one possible world, there exists an object x that has this property).
- **Definition 1:** An object x is God-like if, and only if, x has all positive properties.
- **Axiom 3:** The property of being God-like is itself a positive property.
- **Theorem 2:** It is possible that there exists a God-like object x (in at least one possible world, there exists a God-like object x).
- **Definition 2:** A property φ is an essential property of an object x if, x has property φ, and every property ψ of x necessarily (in all possible worlds) and generally (for all objects) follows from φ.
- **Axiom 4:** If a property φ is positive, then it is necessarily positive (positive in all possible worlds).
- **Theorem 3:** If x is God-like, then being God-like is an essential property of x.
- **Definition 3:** An object x "exists necessarily" if each of its essential properties φ applies, in each possible world, to some object y.
- **Axiom 5:** "Necessary existence" is a positive property.
- **Theorem 4:** It is necessarily true (true in all possible worlds) that a God-like object exists.

Most criticism of Gödel's proof is aimed at its axioms: as with any proof in any logical system, if the axioms of the proof depends on are doubted, then the conclusions can be doubted! It is particularly applicable to Gödel's proof – because it is based on five axioms which are considered questionable. A proof does not necessitate that the conclusion be correct, but rather that by accepting the axioms, the conclusion follows logically.

And once again, if we need to repeat ourselves..., Gödel's ontological proof above is not evidence, since the empirical scientific method that describes reality is based on inductive and abductive logic. The modal logic on which the above proof is based is disconnected from these two and does not allow us to test and verify reality; this is why empirical scientists reject modal logic as a tool for investigating the World.

We can also prove that most gods doesn't exist using logic (i.e. a syllogism):

- Premise (major premise): Everything that exists has a cause[5]
- Property (minor premise): God is a concept without a cause
- Therefore: God has no cause therefore he does not exist

Or formally:

$$\begin{array}{ll} \text{Ax. 1.} & \exists P \forall x P(x) \\ \text{Df. 1.} & \mathcal{G} \rightarrow \neg P(x) \\ \text{Th. 1.} & \Box \neg P(\mathcal{G}) \rightarrow \nexists \mathcal{G} \end{array}$$

Which is a bit similar in idea to this proof:

- Major premise: Major premise: If God can exist without a cause then something can exist without a cause
- Minor premise: If something exists without a cause then why not the Cosmos[6]
- So therefore God solves nothing given that the existence of a God is a problem as big as that of the existence of the Cosmos

Another well known proof of the non-existence of some gods (typically abrahamic one) is (based on the catechism of the Catholic Church, number 385):

- God's omnipotence implies that he can prevent evil
- The goodness of God implies that God must prevent all evil

---

[5] We known since the emergence of the development of quantum physics and quantum cosmology that this premise is obviously false as we will prove during our study of these two fields of physics later!

[6] Indeed we will prove during our study of Cosmogony that contrary to an urban legend peddled by the mass media and bad science popularizers, our observable universe is without cause and extends in a container that is usually named the "cosmos" in which time does not exist.

- However evil exist
- So a good and all-powerful God cannot exist

The philosopher PhD Michael L. Martin has shown that it is possible to prove that an omnipotent god cannot exist. Here is the procedure (syllogism):

1. (major premise) Logic only makes sense if it establishes principles that are necessarily true (principle of non-contradiction). For example, if $1 + 1 = 2$ is not necessarily true, the result becomes variable and can no longer prove anything logically.
2. (minor premise) If Logic is subservient to a god (created by it and contingent upon it), its principles are no longer necessary, but entirely dependent on that god (principle of excluded middle). Therefore, this god can change the status of logical relations at will, which potentially renders Logic invalid (modus ponens).
3. According to the major premise, if a god exists, then Logic is potentially invalid and cannot allow us to reach certain conclusions. Therefore, Logic can no longer be used to definitively prove the existence of a god... if one exists.
4. According to (3), if we want to use Logic to prove the existence of a god with certainty, we must admit that the god cannot change the laws of logic (monotonicity of implication). Therefore, Logic can only lead to the conclusion that an omnipotent god cannot exist!
5. In conclusion, if Logic is a valid means of proving assertions, then it is logically proven that an omnipotent god cannot exist.

> ❞ *The question of the truth of a religion is one thing, but the question of its usefulness is another. I am as firmly convinced that religions do harm as I am that they are untrue.* ❞
>
> Bertrand Russell

quote 5.1:197.#35

Another famous similar example is the proof of the existence of unicorns...! Indeed, consider we want top prove that unicorns, i.e. horses with one horn, exist. The proof consist rhetorically on the following sequence:

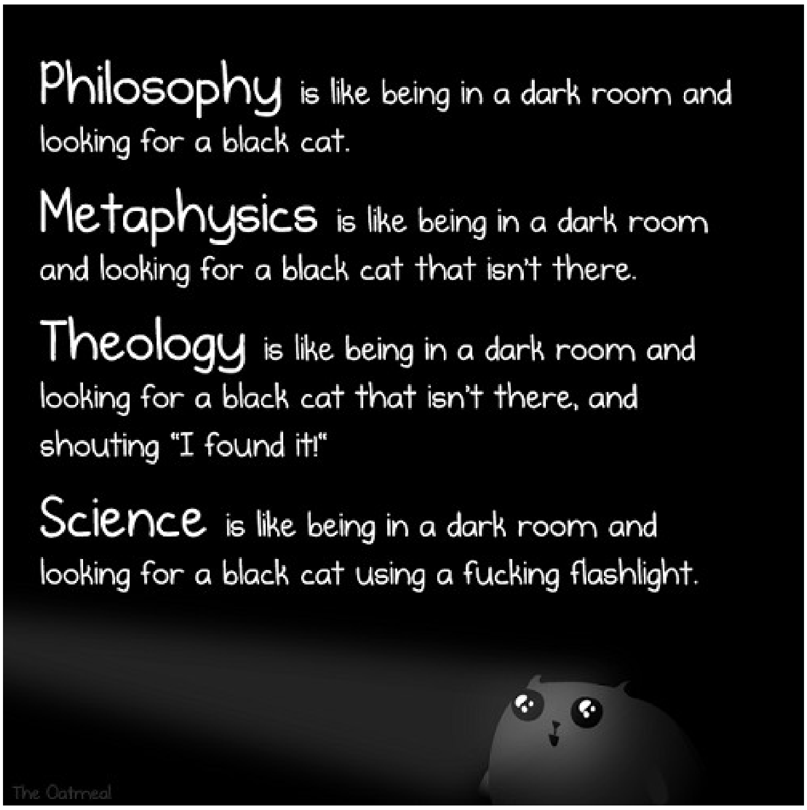
- To prove: Unicorns, i.e. a horses with one horn exist
- (Df. 1.) Unicorns are as we all know horses with one horn!
- (Ax. 1.) Let us suppose the contrary, that unicorns do not exist!
- (Th. 1) Unicorns does not have a horn since, a non-existent entity cannot have anything...
- (Df. 2) But this contradicts the fact that unicorns have one horn by definition

- (Df. 3) This contradiction occurred for wrongly assuming that unicorns do not exist
- (Th. 4) Q.E.D. Hence, unicorns exist!

Formally the above can be rewritten:

Df. 1. $\forall x(\text{Unicorn}(\text{x}) \Rightarrow \text{HasHorn}(\text{x}))$
Ax. 1. $\neg\exists x\, \text{Unicorn}(x)$
Th. 1 $\forall x(\text{Unicorn}(x) \Rightarrow \neg\, \text{HasHorn}(x))$
Df. 2 $(\forall x(\text{Unicorn}(\text{x}) \Rightarrow \text{HasHorn}(\text{x})) \wedge \forall x(\text{Unicorn}(x) \Rightarrow \neg\, \text{HasHorn}(x))) \Rightarrow\perp$
Df. 3 $\neg\exists x\, \text{Unicorn}(x) \Rightarrow\perp$
Th. 4 $\Box\exists x\, \text{Unicorn}(x)$

The error in this example is the claim that a non-existent object cannot have attributes/parts, i.e. $\neq \exists(x) \wedge \text{Predicate}(\text{Q}) \Rightarrow \neg Q(\text{x})$. We cannot assert something about the non-existence of unicorns without evidence based science!



Philosophy is like being in a dark room and looking for a black cat.

Metaphysics is like being in a dark room and looking for a black cat that isn't there.

Theology is like being in a dark room and looking for a black cat that isn't there, and shouting "I found it!"

Science is like being in a dark room and looking for a black cat using a fucking flashlight.

5.1.6.1 Some famous logical fallacies

Definition (#5.1.27): The "principle of explosion", or the "principle of Pseudo-Scotus" (falsely attributed to Duns Scotus), is the law according to which any statement can be proven from a contradiction. That is, from a contradiction, any proposition (including its negation) can be inferred from it; this is known as "deductive explosion". Due to the principle of explosion, the existence of a contradiction (inconsistency) in a formal axiomatic system is disastrous; since any statement can be proven, it trivializes the concepts of truth and falsity...!

In symbolic logic, the principle of explosion can be expressed schematically in the following way:

$$P, \neg P \vdash Q \tag{5.1.112}$$

For any statements P and Q, if P and $\neg P$ are both true, then it logically follows that Q is true.

Proof 5.3.2. Below is a formal proof of the principle using symbolic logic:

Step	Proposition	Derivation
1	P	Premise
2	$\neg P$	Premise
3	$P \vee Q$	Disjunction introduction (1)
4	Q	Disjunctive syllogism $(3, 2)$

■ Q.E.D.

Definition (#5.1.28): The "principle of sufficient reason" (PSR) states that everything must have a reason (explanation) or a cause. The principle was articulated and made prominent by Gottfried Wilhelm Leibniz, with many antecedents, and was further used and developed by Arthur Schopenhauer and Sir William Hamilton, 9th Baronet. It can be stated in various forms that are:

- For every entity X, if X exists, then there is a sufficient explanation for why X exists.
- For every event E, if E occurs, then there is a sufficient explanation for why E occurs.
- For every proposition P, if P is true, then there is a sufficient explanation for why P is true.

In symbolic logic, the principle of sufficient reason can be expressed schematically in the following way:

$$\forall P \exists Q (Q \rightarrow P) \tag{5.1.113}$$

It is an open question whether the principle of sufficient reason can be applied to axioms within a logic construction like a mathematical or a physical theory, because axioms are propositions accepted as having no justification possible within the system. However, the reader must remember that Gödel has shown that for every sufficiently expressive deductive system a proposition exists that can neither be proved nor disproved ! The principle of sufficient reason demands that everything must have a reason. So what is the reason for the principle itself? There isn't one - it's simply stated as an axiom with all what that implies...

The indeterministic interpretations of Quantum Mechanics[7] (Copenhagen and the like) that declare probabilistic predictions complete as to what there is to be known prior to the collapse contradicts the principle of sufficient reason. However other interpretation like the Many World one doesn't.

Remark

The philosopher Robert Nozick also said Quantum Mechanics does violate the principle of sufficient reason. Only a weakened form of the PSR can survive. The mathematician John Conway who wrote on quantum foundations also explicitly stated the original principle of sufficient reason contradicts Quantum Mechanics as such.

Now that we have presented most famous logical fallacies, let us recall all symbols seen so far:

---

[7] For example, the decay of a given radioactive atom has no cause, it is a probabilistic event. According to the Copenhagen interpretation of Quantum Mechanics there are no hidden parameters which give a sufficient cause - not to name a sufficient reason! Furthermore Bell showed that hidden variables weren't possible!

Connective	Symbol	Statement
TRUE value	$\top$	Logical statement is true
FALSE value	$\bot$	Logical statement is false
AND	$\wedge$	Conjunction
OR	$\vee$	Disjunction (inclusive or)
XOR	$\oplus$	Exclusive or
NOT	$\neg, \bar{p}$	Negation
if...then	$\rightarrow, \Rightarrow$	Implication (conditional statement) (necessary condition)
if and only if	$\leftrightarrow, \Leftrightarrow$	Biconditional
equivalent to	$\equiv$	Equivalence
there exists	$\exists$	Existence
there does not exists	$\nexists$	Non-Existence
there is exactly	$\exists!$	Unique Existence
for all	$\forall$	Quantifier
because	$\because$	Because / Since
therefore	$\therefore, \Longrightarrow$	Therefore / Consequence
proves that	$\vdash$	
is not provable	$\nvdash$	
is a tautology	$\models$	Tautology
is a contradiction	$\nvDash$	Contradiction
set of formulas	Γ	
possibly	$\Diamond$	Non-obligatory assumption
end of proof	$\square, \blacksquare$	
code number of the Gödel sentence G	$\ulcorner G \urcorner$	

Table 5.14: **Common symbols in Classical Logic and Proof Theory**

Remark

The logical equivalence $\equiv$ is by tradition something that goes outside of a logical statement (between two of them in particular). If and only if $\leftrightarrow, \Leftrightarrow$ is a symbol that belongs inside a logical statement.

To summarize, below we give a table with most common tautologies, inferences rules and fallacies:

PROPOSITIONAL LOGIC RULES AND FALLACIES

Name	Formula	Description
Tautology	$\varphi = p(x) \therefore A \Rightarrow A$ (i.e. $\models A$)	assertion that A is true in every possible interpretation
Law of Identity	$\forall A : A = A$	for all A, A is what it is
Law of Non-Contradiction	$\neg(A \wedge \neg A)$	A cannot not be and be at the same type its opposite
Law of excluded middle	$A \vee \neg A$	every thing has a given quality or has the negative of that quality
Modus Ponens	$[(p \rightarrow q) \wedge p] \Rightarrow q$	if p then q; p; therefore q
Modus Tollens	$[(p \rightarrow q) \wedge \neg q] \Rightarrow p$	if p then q; not q; therefore not p
Hypothetical Syllogism	$[(p \rightarrow q) \wedge (q \rightarrow r)] \Rightarrow (p \rightarrow r)$	if p then q; if q then r; therefore, if p then r
Disjunctive Syllogism	$(p \vee q; \neg p) \therefore q$	either p or q; not p; therefore, q
Constructive Dilemma	$(p \rightarrow q) \wedge (r \rightarrow s); p \vee r \therefore q \vee s$	if p then q; and if r then s; but either p or r; therefore either q or p
Destructive Dilemma	$(p \Rightarrow q) \wedge (r \Rightarrow s); \neg q \vee \neg s \therefore \neg p \vee \neg r$	if p then q; and if r then s; but either not q or not s; therefore rather not p or not r
Simplification	$[(p = \top) \wedge (q = \top)] \therefore p = \top$	p and q are true; therefore p is true
Conjunction	$(p = \top, q = \top) \therefore p \wedge q$	p and q are true separately; therefore they are true conjointly
Addition	$p = \top \therefore p \vee q$	p is true; therefore the disjunction (p or q) is true
Composition	$[(p \rightarrow q) \wedge (p \rightarrow r)] \Rightarrow [p = \top \rightarrow (q \wedge r) = \top]$	if p then q; and if p then r; therefore if p is true then q and r are true
De Morgan’s Theorems	$\neg(p \wedge q) \equiv (\neg p \vee \neg q)$ $\neg(p \vee q) \equiv (\neg p \wedge \neg q)$	the negation of (p and q) is equiv. to (not p or not q) the negation of (p or q) is equiv. to (not p and not q)
Commutation	$(p \vee q) \equiv (q \vee p)$ $(p \wedge q) \equiv (q \wedge p)$	(p or q) is equiv. to (q or p) (p and q) is equiv. to (q and p)
Association	$[p \vee (q \vee r)] \equiv [(p \vee q) \vee r]$ $[p \wedge (q \wedge r)] \equiv [(p \wedge q) \wedge r]$	p or (q or r) is equiv. to (p or q) or r p and (q and r) is equiv. to (p and q) and r
Distribution	$[p \wedge (q \vee r)] \equiv [(p \wedge q) \vee (p \wedge r)]$ $[p \vee (q \wedge r)] \equiv [(p \vee q) \wedge (p \vee r)]$	p and (q or r) is equiv. to (p and q) or (p and (p or r) p or (q and r) is equiv. to (p or q) and (p or r)
Double Negation	$p \equiv \neg\neg p$	p is equivalent to the negation of not p
Transposition	$(p \rightarrow q) \equiv (\neg q \rightarrow \neg p)$	if p then q is equiv. to if not q then not p
Material Implication	$(p \rightarrow q) \equiv (\neg p \vee q)$	if p then q is equiv. to either not p or q
Material Equivalence	$(p \equiv q) \equiv [(p \rightarrow q) \vee (q \rightarrow p)]$ $(p \equiv q) \equiv [(p \wedge q) \vee (\neg p \wedge \neg q)]$	(p is equiv. to q) means, either (if p is true then q is true) or (if q is true then p is true) (p is equiv. to q) means, either (p and q are true) or (both p and q are false)
Exportation	$[(p \wedge q) \rightarrow r] \equiv [p \rightarrow (q \rightarrow r)]$	(if p and q are true then r is true) is equivalent to (if q is true then r is true, if p is true)
Importation	$[p \rightarrow (q \rightarrow r)] \equiv [(p \wedge q) \rightarrow r]$	if p is true then (if q then r) is true is equivalent to p and q is true then r is true
Principle of explosion (fallacy)	$\forall p, q : (p \wedge \neg p = \top) \vdash q$	for any statements p and q, if p and $\neg p$ are both true, then we can always prove that q is true
Vacuous truth (fallacy)	$\forall x \in P : Q(x)$ where $P = \varnothing$	statement that asserts that all members of the empty set have a certain property
Existential fallacy	$A \Rightarrow B, B \therefore A$	one presupposes that a class B has members A when one is not supposed to do so
Existence property fallacy	$\exists A \neq P(A)$	existence is a quantifier but not a predicate (i.e. existence is not a property!)
Affirming the consequent (fallacy)	$(P = \top \wedge C = \top); C = \top! \therefore P = \top$	if the premise and conclusions are both true, the conclusion is not a necessary consequence of the premise
Denying the antecedent (fallacy)	$(P = \top \rightarrow C \Rightarrow \top); C = \top! \therefore P = \top$	while the conclusion may be true, it does not follow from the premise
Affirming a disjunct (fallacy)	$A \vee B = \top; B = \top! \therefore A = \perp$	the conclusion does not follow from the premise as it could be the case that A and B are both true
Denying a conjunction (fallacy)	$(B \vee A) = \perp! \therefore A = \top$	A and B cannot be both true the conclusion does not follow from the premise as it could be the case that A and B are both false
Undistributed middle (fallacy)	$Z \in B, Y \in B \therefore Y = Z$	it is not necessarily true that "all Bs are Zs," which is ignored in the argument
False dichotomy (fallacy)	$(p \rightarrow q), (r \rightarrow q), (p \vee q) \therefore q$	it is a false dichotomy as whatever the choice it leads to the same conclusion
A priori argument (motivated reasoning) (fallacy)	$\overline{\Gamma, A \vdash A}^{\text{ax}}$	using an axiom to prove the axiom itself doesn’t make sense as the axiom is therefore beyond refutation

Table 5.15: Most well known rules of inference and fallacies in Classical Logic

With all these tools it’s now easy to disprove any ontological argument for any of the gods of the 45 monotheistic revealed religions actually practised around the world! We already have for example explained the fallacies in Gödel’s ontological argument earlier above. Another type of ontologic arguements are those used mainly by the eleven Abrahamic religions and named the "Thomas Aquinas' Five Ways[8]" (Thomas d'Aquinas was a Dominican friar and priest and influential philosopher and theologian from the 113th century according to holocene calendar):

- **The argument of the unmoved mover:** As particles pop-up from vacuum with non-zero speed in the quantum realm, they don't have any mover. They just extract, as we will prove during our study of Quantum Physics, their energy from the vacuum zero-energy level that has a non-zero value (at small scales principle of conservation of energy is still conserved as a photon is it's own anti-particle and other particles appear with opposite counterpart but at cosmological scales the principle of conservation of energy is violated as we will also prove it). Also light emitted from atoms caused by electrons levels changes aren't accelerated by a mover until they reach the speed of light, they emerge from vacuum instantaneously at the speed of light! Thomas d'Aquinas wasn't able to know that Quantum Physics would exist and most philosophers are illiterate in science and doesn't know nothing about vacuum fluctuations (typically they know nothing about the Euler–Heisenberg Lagrangian nor the Uehling potential).

- **Causation of existence:** Theoretically nothing forbids for example our universe to create itself. Indeed according to Roger Penrose speculative Conformal Cyclic Cosmology (CCC) model the end of the Universe generates it's own next beginning. However at the contrary of the science evidence based results that refutes Aquinas first way introduced previously, there are for the moment in the early 121st century (according to holocene calendar) no strong experimental evidence for Roger Penrose model.

- **Contingent and necessary objects:** This way of Aquinas is proven mathematically wrong by formal logic as it is based on three first order logic fallacies: 1) the a priori argument where Aquinas uses an axiom that leads to a conclusion that is the axiom itself (see the table of logical fallacies above) 2) the principle of explosion as Aquinas uses a contradiction to prove a statement (see the table of logical fallacies above) 3) the existence property fallacy as Aquinas uses a quantifier that is not a predicate (see the table of logical fallacies above).

- **Argument from degrees and perfection:** This one is different from the previous ways! It's primarily semantical nonsense based on solely linguistic definitions that doesn't prove a thing! However an nuclear chemist would very likely say that this argument is scientifically speaking pure nonsense and therefore wrong...

- **Argument from intelligent design:** This way of Aquinas uses a ill-defined concept in science. The "mind" is indeed a philosophical/religious construct, with a fluid definition that is difficult to pin down. No one can prove anything without clearly scientifically defining it and there isn't (sadly) any scientific consensus about its definition still in this early 121st century (holocene calendar). Nevertheless, we actually agree that some objects clearly are what the layman would say "mindless" (a stone for example) while others appear to have what we the layman commonly names a "mind" in vernacular usage.

Obviously we strongly advise the reader to check the original text of Thomas d'Aquinas because taking them out of their context can be misleading (some philosophers always argue that

---

[8] The reader must not forget that philosophers aren't skilled scientists and that's a severe handicap when confronting a philosophical argument to evidence based science.

Aquinas five ways are wrongly interpreted when the latter are debunked by modern science) and we must also remember that nowadays someone like Thomas d'Aquinas wouldn't even obtain a high-school grade in modern science...

Therefore, we can conclude that theist attempt to prove the existence of the god of one of the 45 revealed monotheistic religions based on rhetorical formal logic is easily exposed as vacuous!

5.1.6.2 Is logic a science?

quote 5.1:204.#36

> *Logic is the art of going wrong with confidence.*
>
> Joseph Wood Krutch

Let us recall that this question in the broad sense of the word "science" has obviously a positive answer. However as we have seen in the introduction of this book, there are different sciences!

If we designate by "science" any field centered around the "scientific method": making hypotheses, running experiments in the purpose to refute (i.e. falsify) them and so on, then Logic is nothing like this (logic doesn't have for purpose to refute his premises). Experimental science is inherently based on the physical, observable world. While there is deep thinking involved, a posteriori assumptions, the ultimate arbiter of any experimental scientific idea is the sensible world, through experimentation.

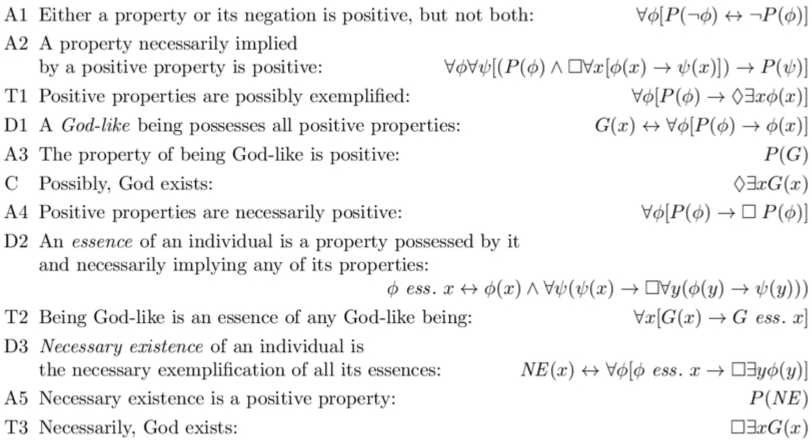
Logic, on the other hand, is entirely self-contained. It's the study of formal systems: sets of axioms and rules on how to derive theorems. Logic is a game where all the rules are made up.

Although logic is not an empirical science or a physical science, it is nonetheless a science in the broad sense of the term, i.e., a systematic body of rational knowledge.

While any use of logic probably may falls back to the real world, logic itself doesn't. It's entirely self-contained. When we prove something logically, we are not making a direct statement about the universe: we are making a claim consistent with the assumptions of our logic system and that may furthermore not be refutable (i.e. not falsifiable) - or even worse - the major well known historical flaw/issue of logic (we have more than 2500 years of evidence of such flaws) is that the conclusion of any logical reasoning is always in the premises. The relationship between logic and the universe is separate: it's what makes logic useful, but it is not what makes logic.

One of the most well known example in "modern" graduate level science of fallacious logic is the *Kalâm cosmological argument* (an argument for the existence of a deity that created our Universe) the second one is very likely the Pascal's wager. The premise of the Kalâm cosmological argument, «*Whatever begins has a cause*», may be kinda logic for an undergraduate or scientifically illiterate individual or a non-professional physicist. But for professionals postgraduate level physicists this is proven mathematically and experimentally wrong at least since the years 11950 (we will see the proofs in the section of Wave Quantum Physics page 4688 and Quantum Gravity page 6074 much later in this book). So anyone using this argument as a logical claim just provide evidence for his ignorance of modern physics[9] and also of logics itself (as the conclusion is in the premise... facepalm). And furthermore as we have also seen during our introduction of this book, a claim or a quote is at maximum an evidence of level 02 (see page 60)...

Very likely the only well known example in "modern" postgraduate level science of fallacious logic (where again the conclusion is in the premises[10]) is the *Gödel's ontological proof* for the existence of (very likely...) the Christian deity... as it suits well Gödel's beliefs... Most theist share the following proof summary on social network this without obviously recognizing all biases as they are for the huge majority of them scientifically illiterate:



A1	Either a property or its negation is positive, but not both:	$\forall\phi[P(\neg\phi)\leftrightarrow\neg P(\phi)]$
A2	A property necessarily implied by a positive property is positive:	$\forall\phi\forall\psi[(P(\phi)\wedge\Box\forall x[\phi(x)\rightarrow\psi(x)])\rightarrow P(\psi)]$
T1	Positive properties are possibly exemplified:	$\forall\phi[P(\phi)\rightarrow\Diamond\exists x\phi(x)]$
D1	A *God-like* being possesses all positive properties:	$G(x)\leftrightarrow\forall\phi[P(\phi)\rightarrow\phi(x)]$
A3	The property of being God-like is positive:	$P(G)$
C	Possibly, God exists:	$\Diamond\exists xG(x)$
A4	Positive properties are necessarily positive:	$\forall\phi[P(\phi)\rightarrow\Box\, P(\phi)]$
D2	An *essence* of an individual is a property possessed by it and necessarily implying any of its properties:	$\phi\ ess.\ x\leftrightarrow\phi(x)\wedge\forall\psi(\psi(x)\rightarrow\Box\forall y(\phi(y)\rightarrow\psi(y)))$
T2	Being God-like is an essence of any God-like being:	$\forall x[G(x)\rightarrow G\ ess.\ x]$
D3	*Necessary existence* of an individual is the necessary exemplification of all its essences:	$NE(x)\leftrightarrow\forall\phi[\phi\ ess.\ x\rightarrow\Box\exists y\phi(y)]$
A5	Necessary existence is a positive property:	$P(NE)$
T3	Necessarily, God exists:	$\Box\exists xG(x)$

Most criticism of Gödel's proof (and other equivalent one) is aimed at its axioms (premises): as with any proof in any logical system, if the axioms of the proof depends on are doubted, then the conclusions can be doubted (that why in logic you can build any proof and that afterwards you need experimental science to sort the garbage from the evidence). It is particularly applicable to Gödel's proof – because it rests on five axioms, some of which are questionable (there are more than $10,000$ gods around the World for example and most of them don't have positive[11] properties... especially in the Abrahamic religions) and some other are refuted theoretically and experimentally (the axiom A1 is wrong as we know from our actual knowledge of Quantum Physics as proven in the chapter on that topic at page 4688) since the 11950 at least... A proof does not necessitate that the conclusion be correct, but rather that by accepting the axioms, the conclusion follows logically. Also Gödel's proof is wrong because again... the conclusion is in the premises. And finally Gödel's ontological proof also suffer from the Gödel's incompleteness theorems!

In a certain set, logic is pure "thought-stuff". It's pure reasoning distilled to a set of simple, verifiable rules. The ultimate arbiter for any logical proof is the logic system, not the universe at large. We can even have perfectly reasonable logic systems that do not map back to our universe at all! It would still be logic, but it probably wouldn't be very interesting or useful! For all these reasons, you can't run an experiment on logic! On the one hand, there is nothing to experiment on, logic is only about validity (when science is about evidence). Again, logic is perfectly self-contained and not dependent on physical reality. On the other hand, logic does not have uncertainty: either you have a proof for something, or you don't. So you don't need to run experiments in the first place, since you have a more powerful notion of proof within the system itself.

---

[9] Another such typical example are that because of existence of truth table, some people again argue that logic can lead to true conclusions. But truth tables depends again on the premise and if the premise is false... guess what!

[10] An argument is "circular" just in case there is a premise, either implicit or explicit, that is logically equivalent to the conclusion. In many cases, circularity is a problem and we name such circularity a "vicious circularity".

[11] And that concept wasn't defined by Gödel...

So logic doesn't involve any experimental configuration and doesn't describe our observable Universe. It is therefore definitely not a scientific method[12]! Let us see a non-exhaustive logical/intuition errors list from some famous philosophers, engineers and scientists that prove the point:

- Aristotle wasn't the first to say that the Earth occupies the center of the universe, but he was the most dogmatic about it, and believed he had established it to be incontrovertibly true by using... logic.
- Euclid was sure by logic that the axiom of parallels (parallel postulate) should always have been true. However modern mathematics and modern experimental science proved he was wrong.
- According to Kepler's logic, planet orbits are ellipses because of his religious faith in perfection. We know now that in fact planets describe, from the point of view of a centered galactic observer, a helicoidal movement and describe a given ellipse whose parameters changes across billions years and may even become chaotic over time.
- According to Boyle's intuition (logic), light had to propagate in something named an "aether". This was later shown experimentally and theoretically wrong.
- According to Darwin's intuition (logic), characteristics of the mother and the father simply get blended in the offspring just as a can of black paint and a can of white paint blend to generate gray when combined. This was proven wrong later by Mendel and modern genetics.
- According to Kelvin's reasoning method, Earth's age would have been 50 times younger than what modern radio-isotopic dating methods provide as evidence.
- According to Kelvin's logic, heavier than air flying machines must have been impossible...
- In the early 120th century (holocene calendar), the vast majority of geologists rejected Wegener's idea of continental drift, arguing that ocean floors were fixed and continents could not logically move.
- According to Einstein's intuition (logic), the Universe must have been static. So he introduced the cosmological constant in it's theory. Evidence proved his logic was flawed.
- According to Einstein's (and others!) intuition and logic, spooky action at a distance (entanglement) was something impossible and wrong.
- Einstein denied several times that Black Holes could form.

---

[12] There is a quite famous 700 pages book [503] written by a philosopher that presents and criticize in details (in a horrible way because obviously most philosophers don't know how to write properly textbooks in LaTeX) most existing ontological proofs and disproofs of gods but however without relying to experimental scientific evidence and focusing only on the main Abrahamic religions. Typical errors of most occidental philosophers by the way...

- In the early days of quantum mechanics, Einstein tried to show that the uncertainty principle was not valid. By 11927 (holocene calendar) he had become convinced of its utility, but he always opposed it
- Eddington's failed to take Chandrasekhar's theory of gravitational collapse seriously because for him it was something illogical.
- etc...

Obviously some people may argue that the errors above were technical errors and not logical errors. That latter point is a matter of semantic !

But how is experimental science a logic?

Well, the core concept in the scientific method is inductive reasoning. Roughly put, it's the idea that if we do X and Y happens $1,000$ times in a row, X will probably lead to Y next time too. If we do this enough times - and are sufficiently careful - we'll just conclude that X causes Y. That's the reason experiments make sense and let us predict the future. As we will see during our study of statistical hypothesis test later, these latter are build on a kind of probabilistic inference and therefore on logic. So the scientific logic is based on logic but... logic is not a scientific method!

Oh! And by the way... Some non-academic people argue that there is only one unique "scientific method". It is quite ambiguous to make such a statement as it is constantly evolving! The documented scientific method by Francis Bacon in 1620 has almost nothing to do anymore with the scientific method of the early 121st century (holocene calendar)!

To finish, let us quote now a part of a text written by Donald E. Simanek on it's website, because it's worth it:

«Scientists do not arrive at models and theories by application of logic. They arrive at them by many processes lumped under the name "induction". Induction cannot be reduced to a set of logical rules (though many have tried). To see patterns (sometimes subtle and hidden ones) in data and observations requires creative ability. This is the ability to think ahead and say: «*What model, set of statements (laws) or theoretical construct could I devise from which these observations and data might be deduced?*»

We can't find, discover, or construct scientific laws and theories by mathematics and logic alone. But we can derive testable and useful results by application of mathematics and logic to laws and theories, and if those deduced results pass experimental tests, our confidence in the validity of the theory from which they were derived is strengthened.

Some people are profoundly disturbed by the fact that reason alone can't generate truths. When the use of mathematics and logic in science is explained to them they respond, «*If mathematics and logic can't produce absolute truths, then they produce only untruths or partial truths, and are therefore worthless.*» This sentence is itself an example of nonsense clothed in the appearance of logic.

It must be admitted at the outset that science is not in the business of finding absolute truths. Science proceeds as if there are no absolute truths, or if there are such truths, we can never know what they are. As the pre-Socratic skeptics observed: If we were to stumble upon an absolute truth, we'd have no way to be certain it is an absolute truth. The models and theories of science are approximations to nature - never perfect. But in most cases we know rather well how good they are. We can state quantitatively the limits of uncertainty of numeric results, and their range of applicability. Yet there's always the possibility that we may find exceptions to one of our accepted laws, or may even find alternative theories that do a better job than older ones.

[...]

Some critics of science attack this process of science, on the grounds that it cannot produce absolute truths. Theirs is a black/white view of the scientific process. Never mind that they have not proposed any other process that is capable of producing anything near the power and comprehensiveness of present science. They say that "Theory X" isn't perfect therefore it is "wrong".

[...]

The fact that science claims no absolute truths is seized upon by people who hold strong religious beliefs and who dislike those conclusions of science that run counter to their emotional convictions. To them, if a thing is not absolutely and finally true, it is false, and therefore the methods used to formulate it must be flawed.»

5.2. Numbers

THE basis of mathematics, apart the reasoning (see section Proof Theory page 131), is undoubtedly to ordinary people: arithmetic. It is therefore mandatory that we make a stop on it to study its origin, some of its properties and consequences.

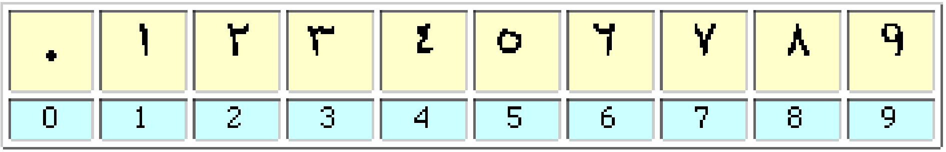
The numbers, like geometric figures are the basis of Geometry, are the basis of Arithmetic. These are also the historical basis because mathematics probably started with the study of these objects, but also the educational foundation, because it is by learning to count that we enter in the world of mathematics.

The history of numbers, also sometimes named "scalar", is far too long to be told here! But we can only advise you one of the best book on the subject: The Universal History of Numbers (approximately 2,000 pages in three volumes) Georges Ifrah, ISBN: 2221057791.

But here's a little flange of this latter which seems fundamental to us:

Our current decimal system, on base 10, uses the digits 0 to 9, named "Arabic numbers", but the fact of Indian origin (Hindus). The first numbers seems to have been invented in the 97th (holocene calendar) in India by Brahmagupta, an Indian mathematician. he invented the figures in Devanagari.

Indeed, the Arabic numbers (of Indian origin...) in the table below are the first line and we see that they are significantly different from the "Indian numbers" of the second line:



٠	١	٢	٣	٤	٥	٦	٧	٨	٩
0	1	2	3	4	5	6	7	8	9

Figure 5.6: Indo-Arabic numbers

You have to read this table as following from left to right: 0 "zero", 1 "one", 2 "two", 3 "three", 4 "four", 5 "five", 6 "six", 7 "seven", 8 "eight, 9 "nine". This system is much more efficient than the Roman numerals (try doing a calculation with Roman notation system you will see...).

It is commonly accepted that these numbers were introduced in Europe only about the year 11000 (holocence calendar). Used in India, they were transmitted by Arabs to the Western world by the Pope Gerbert of Aurillac during his stay in Andalusia at the end of the 109th century (holocene calendar).

Remark

The French word "chiffre" (number) is a corruption of the Arabic word "sifr" meaning "zero". In Italian, "zero" is "zero", and seems to be a contraction of "zefiro", we again see here an Arabic root but the "zero" could also be of Indian origin... So the words "chiffre" and "zero" have the same origin.

The early use of a numerical symbol for the "nothing" in the sense of "no amount", i.e. our "zero" is because the Indians used a system named "positional system". In such a system, the position of a digit in the writing of a number expresses the power of 10 and the number of times it occurs ... and the absence of a position in this system arise from huge proofreading problems and could lead to large errors in calculations. The revolutionary and simple introduction of the concept of "nothing" allowed a proofreading without error of numbers.

The absence of a power is denoted by a small circle...: the zero. Our current system is thus the "decimal and positional system".

✍**Example:**

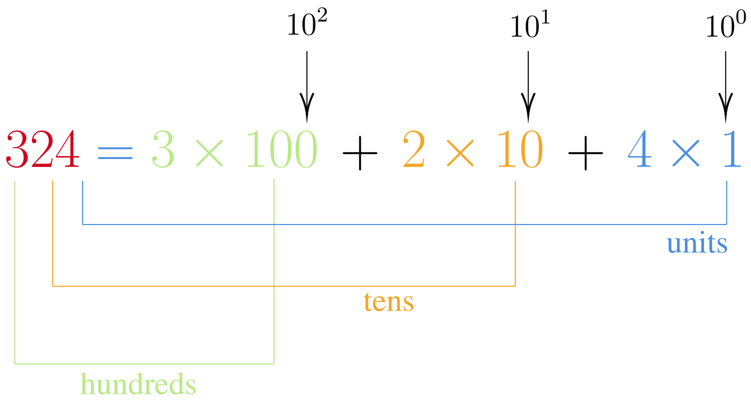


Figure 5.7: **Description of decimal and positional system**

The number 324 is written from left to right as three hundred: 3 times 100, two tens: 2 times 10 and four units: 4 times 1.

Thus a "decimal number" is thus a number that has a finite writing in base 10.

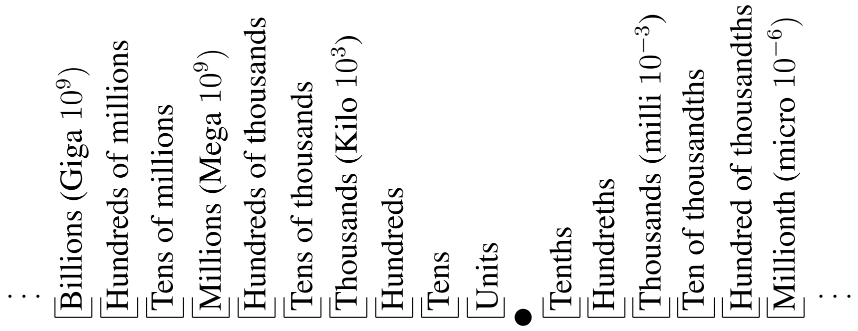
We sometimes see (and this is recommended) a thousands separator represented by a coma in United States (put all three numbers from the first from the right for the whole numbers). Thus, we write $1,034$ instead of 1034 or $1,344,567,569$ instead of 1344567569. Thousand separators permits to quickly quantify the magnitude of the read numbers.

So:

- If we see only one coma we know that the number is about thousands
- If we see two apostrophes we know that the number is about millions

- If we see three apostrophes we know that the number is about billions
- etc.

and so on... also with decimals this gives:



. . .
Billions (Giga 10^9)
Hundreds of millions
Tens of millions
Millions (Mega 10^9)
Hundreds of thousands
Tens of thousands
Thousands (Kilo 10^3)
Hundreds
Tens
Units
●
Tenths
Hundreths
Thousands (milli 10^{-3})
Ten of thousandths
Hundred of thousandths
Millionth (micro 10^{-6})
. . .

Figure 5.8: **Scale representation of the positional system**

In fact, any integer other than the unit can be taken as the basis of a numbering system. We have for example the binary, ternary, quaternary, ..., decimal, duodecimal numbering systems which correspond respectively to the bases two, three, four, ..., ten, twelve.

A generalization of what has been seen above, can be written as follows:

Any positive integer N can be represented in a base b as a sum, where each coefficient a_i are multiplied by their respective weight b^i. Such as:

$$N=a_{n-1}b^{n-1}+a_{n-2}b^{n-2}+\ldots+a_1b^1+a_0b^0 \tag{5.2.1}$$

More elegantly written:

$$\boxed{N=\sum_{i=0}^{n-1}a_ib^i} \tag{5.2.2}$$

with $a_i\in[0,b-1]$ and $b_i\in[1,b^{n-1}]$

Remarks

R1. As frequently in mathematics, we will replace numbers with Latin or Greek letters in order to generalize their representation. So when we speak of a base b, the value of b can take any positive integer value $1,2,3,\ldots$

R2. When we take the value 2 for b, the maximum value of N will be 2^n-1. The numbers that are written in this form are named "Mersenne numbers". These numbers can be prime numbers (see further below what a prime number is) if and only if n is also a prime number.

Indeed, if we take (for example) $b=10$ and $n=3$ the largest value we can get will be:

$$(b-1)10^2+(b-1)10^1+(b-1)10^0=900+90+9=999=10^3-1=b^3-1 \tag{5.2.3}$$

R3. When a number is the same read from left to right or right to left, we name it a "palindrome".

5.2.1 Digital Bases

To write a number in base b system, we must first adopt b characters for representing the b first numbers for example in the decimal system: $\{0,1,2,3,4,5,6,7,8,9\}$. These characters are as we already defined them, the "digits" that we pronounce as usual $\{\text{zero}, \text{one}, \text{two}, \text{three}, \text{four}, \text{five}, \text{six}, \text{seven}, \text{eigth}, \text{nine}\}$.

For the written numbers, we make this convention that a digit, placed to the left of another represents the order units immediately above, or b times larger. To take the place of units that may be lacking in certain orders, we use the zero "0" and consequently, the number of digits may vary.

Definition (#5.2.29): For the spoken numbers, we agree to name "single unit", "ten", "hundred", "thousand", etc., units of the first, second, third, fourth order, etc. Thus the numbers $10,11,\ldots,19$ will be readed in the same way in all numbering systems. The numbers $1a,1b,a0,b0,\ldots$ will be readed ten-a, ten-b, a-ten, b-ten, etc. Thus, the number 5b6a71c will be readed:

five million be-hundred sixty-a thousand seven hundred ten-c

This small example is relevant because it shows the general expression of the spoken language we use daily is intuitively in base ten (fault of our education).

Remarks

R1. The rules of mathematical operations defined for numbers written in the decimal system are the same for numbers written in any numbering system.

R2. To quickly operate in any numbering system, it is useful to know by heart all sums and products of two numbers of a single digit.

R3. The decimal seems has its origin in the fact that humans being have ten fingers.

Let's see how we convert a numbering system in another one:

✍**Examples:**

E1. In base ten we have seen above that $142,713$ will be written as:

$$142,713_{10}=1\cdot 10^5+4\cdot 10^4+2\cdot 10^3+7\cdot 10^2+1\cdot 10^1+3\cdot 10^0 \tag{5.2.4}$$

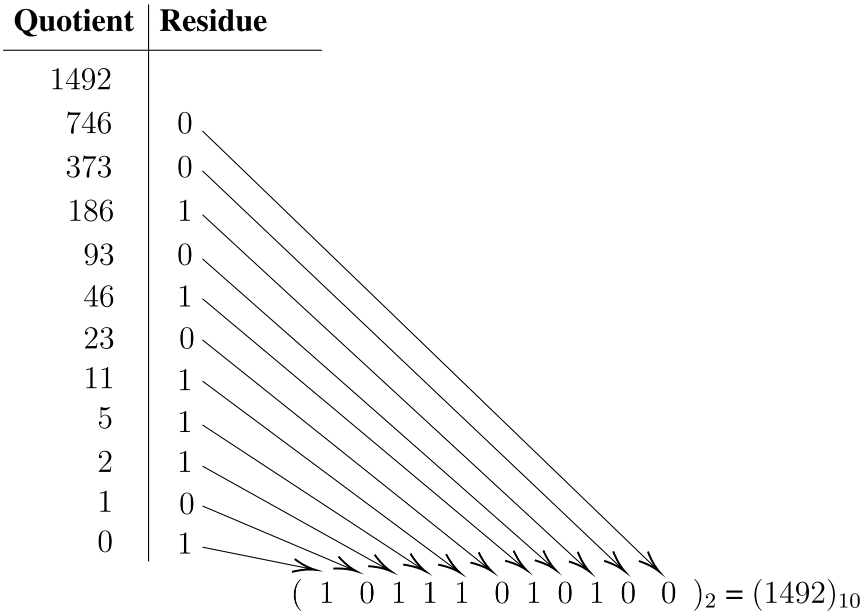
E2. The number 0110 that is in base two (binary base) would be written in base 10:

$$0110_2=0\cdot 2^3+1\cdot 2^2+1\cdot 2^1+0\cdot 2^0=6_{10} \tag{5.2.5}$$

and so on... The reverse operation is often a little trickier (for example the case of the binary base):

✍**Examples:**

E1. Converting the decimal number $1,492$ in binary base is done by successive divisions by 2 of residues and gives (the principle is about the same for all other bases):



Quotient	Residue
1492	
746	0
373	0
186	1
93	0
46	1
23	0
11	1
5	1
2	1
1	0
0	1

$$(1\ 0\ 1\ 1\ 1\ 0\ 1\ 0\ 1\ 0\ 0)_2=(1492)_{10}$$

Figure 5.9: **Decimal to binary conversion**

E2. To convert the number $142,713$ (decimal base) in duodecimal base (base twelve) we have (notation: q is the "quotient", and r is the "residue"):

$$\begin{aligned}\frac{142,713}{12} &\Rightarrow q=11,892 \quad r=9\\ \frac{11,892}{12} &\Rightarrow q=991 \quad r=0\\ \frac{991}{12} &\Rightarrow q=82 \quad r=7\\ \frac{82}{12} &\Rightarrow q=6 \quad r=10\\ \frac{6}{12} &\Rightarrow q=0 \quad r=6\end{aligned} \tag{5.2.6}$$

Thus we have the residues 6, 10, 7, 0, 9 which leads us to write:

$$142,713_{10}=6a709_{12} \tag{5.2.7}$$

where we have chosen for this particular example the symbolism that we have previously defined (a-ten) to avoid any confusion.

5.2.2 Type of Numbers

Now that we know that number is a mathematical object used to count, measure and label it must be know that it exists in mathematics a wide variety of numbers (natural, rational, real, irrational, complex, p-adic quaternions, transfinite, algebraic, constructibles, etc.) since any mathematician may at leisure invent its own numbers just by defining axioms (rules) to manipulate them.

However, there are a few of them that we find much more often than others through this book and some that serve as basic construction for others and which that should be defined sufficiently rigorously (without going to the extremes) in order to know what we will talk about when we will use them.

5.2.2.1 Natural Integer Numbers

The idea of "integer" (the numbers for which there are no decimals) is the fundamental concept of mathematics and comes at the view of a group of objects of the same types (a sheep, another sheep, yet another sheep, etc.).

When the amount of objects in a group is different from that of another group when the speak about a group that is numerically higher or lower regardless of the type of objects in these groups. When the amount of objects of one or multiples groups is equivalent, then we speak about "equality".

To each single object the number "one" or "unit" denoted by "1" in the decimal system will be used.

To form groups of objects, we can operate as follows: to an object, add another object, then another, and so on... each of the clusters, from the point of view of its community, is characterized by a number. It follows from this that a number can be regarded as representing a group of units (single items) such that each unit corresponds to one single object of the collection.

Definition (#5.2.30): Two numbers are said to be "equal" if each of the units of one we can match a unique unit of the other and vice versa (in a bijective way as seen in the section of Set Theory page 407). If this does not hold true when we talk about "inequality".

Below we have a graphical example of a set defined by two inequalities:

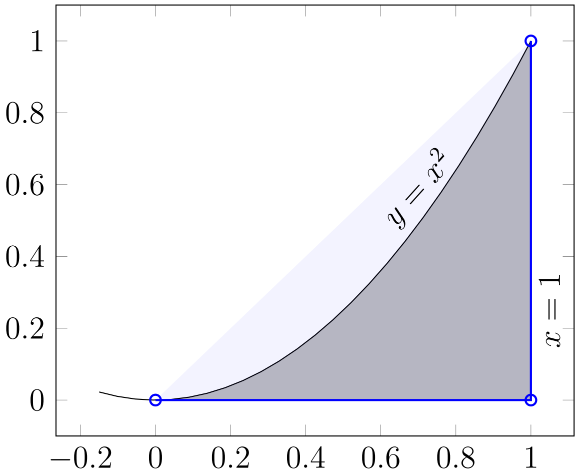


Figure 5.10: $R = \{(x, y) \mid 0 \leq y \leq x^2, x \leq 1\}$

Let us take an object, then another, then to the formed group add again an object and so on. The groups thus formed are characterized by numbers which, taken in the same order as the groups successively obtained, are the "natural sequence $\mathbb{N}$" or "natural integers", also sometimes named "whole numbers", and denoted by:

$$\boxed{\mathbb{N} = \{0, 1, 2, 3, \ldots\}} \tag{5.2.8}$$

To be unambiguous about whether 0 is included or not, sometimes an index (or superscript) is added in the former case:

$$\mathbb{N}^* = \mathbb{N}^1 = \{1, 2, 3, \ldots\} \tag{5.2.9}$$

Remark

The presence of the 0 (zero) in our definition above of $\mathbb{N}$ is debatable since 0 is neither positive nor negative. That is why in many books you will find a definition of $\mathbb{N}$ without the 0 (hence corresponding to $\mathbb{Z}^+$) and therefore the set $\mathbb{N} \cup \{0\}$ (also sometimes denoted $\mathbb{Z}_{\geq 0}$ or $\mathbb{N}_0$) is named the "calculative set" or "whole numbers". But keep in mind that there seems to be no general agreement and it is actually not defined in the ISO 80000 norm series!!!

The components of this natural set can be defined by (we own this definition to the mathematician Frege Gottlob) the following the properties (having read first the section on Set Theory page 378 is strongly recommended...):

P1. 0 (read "zero") is the number of elements (defined as an equivalence relation) of all sets equivalent to (in bijection with) the empty set.

P2. 1 (read "one") is the number of elements of all sets equivalent to the set whose only element is 1.

P3. 2 (read "two") is the number of elements of all sets equivalent to the set whose only element are 1 and 2.

P4. In general, an integer is the number of elements of all sets equivalent to the set of integers preceding it!

The construction of the set of natural numbers is made of the most natural and consistent manner. Natural numbers get their name from what they were, in the beginnings of their existence, to count quantities and things of nature or intervened in human life. The originality of this set lies in the empirical way he has been built since it does not actually the result of a mathematical definition, but more by awareness of the human by the concept of countable quantity, of number and operations that reflect the relations between them.

The question about the origin of $\mathbb{N}$ is therefore the question of the origin of mathematics. And since thousands of years debates confronting the thoughts of the greatest philosophical minds have attempted to elucidate this deep mystery as to whether mathematics is a pure creation of the human mind or whether the man has only rediscovered a science that already existed in nature. Besides the many philosophical questions that the set of Natural numbers can generate, it is nonetheless interesting from an exclusively mathematical point of view. Because of its structure, it has remarkable properties that can be very useful when we practice some given reasoning or calculations.

The sequence of natural numbers $\mathbb{N}$ is unlimited (see section Numbers page 215) but countable (we will this property in details below), because in a group of objects that is represented by a number n, it will be enough to add an object to get another group that will be defined by the integer $n+1$.

Definition (#5.2.31): Two integers that differs from a single positive unit are said to be "consecutive".

5.2.2.1.1 Peano axioms

During the crisis of foundations of mathematics, mathematicians have obviously sought to axiomatize the set $\mathbb{N}$ and we own the actual axiomatisation to Peano and Dedekind.

The axioms of this system include the symbols $<$ and $=$ to represent the relations "smaller than" and "equal to" (see section Operators page 288). They include also the symbols "0" for the number zero and s to represent the "successor" number. In this system, 1 is denoted by:

$$1 = s(0) \tag{5.2.10}$$

named "successor to zero" and 2 is denoted by:

$$2 = s(s(0)) = s(1) \tag{5.2.11}$$

The Peano axioms that builds $\mathbb{N}$ are (see section of Proof Theory page 131 for details on some of the symbols used below):

A1. 0 is a natural number (this permits $\nvdash$ to be not empty).

A2. Every natural number n has a successor, denoted by $s(n)$.

Therefore s is an injective application (see section Set Theory page 406), that is to say:

$$\forall x, y \quad s(x) = s(y) \Leftrightarrow x = y \tag{5.2.12}$$

That is to say that if two successors are equal, they are the successors of the same number.

A3. The successor of a natural number is never zero (therefore $\mathbb{N}$ has a first element):

$$\forall x \quad \neg(s(x) = 0) \tag{5.2.13}$$

A4. If we prove a property φ that is true for x and its successor $s(x)$, then this property is true for any x (this is named the "axiom of recurrence"):

$$(\varphi(x) \Rightarrow \varphi(s(x))) \Rightarrow \forall x\ \varphi(x) \tag{5.2.14}$$

So the set of all the numbers satisfying the four above axioms is denoted by:

So the set of all the numbers satisfying the four above axioms is denoted by:

$$\mathbb{N} = \{0, 1, 2, 3, \ldots, n, \ldots\} \tag{5.2.15}$$

Remark

The Peano axioms allow to build very rigorously the two basic operations of arithmetic in $\mathbb{N}$ that are addition and multiplication (see section Arithmetic Operators page 296 and page 296) and so all the other sets that we will see later (subtraction in $\mathbb{N}$ can not be applied because it can give negative numbers).

5.2.2.1.2 Odd, Even and Perfect Numbers

In arithmetic, study the parity of an integer, its determiner if this integer is or not a multiple of 2. An integer multiple of 2 is an even integer, the others are odd integers.

Definitions (#5.2.32):

D1. The numbers obtained by counting by step of 2 from zero (i.e.. $0, 2, 4, 6, 8, \ldots$) in the set of natural integer numbers $\mathbb{N}$ are named "even numbers".

The n^{th} even number is obviously given by the relation:

$$\mathbb{E}: \quad 2n = n + n \quad \forall \mathbb{N} \tag{5.2.16}$$

Or more aesthetically:

$$\mathbb{E} = \{x \in \mathbb{N} : \exists n \in \mathbb{N}(x = 2n)\} \tag{5.2.17}$$

D2. The numbers we get by counting by step of 2 starting from 1 (i.e. $1, 3, 5, 7, \ldots$) in the set of natural integer numbers $\mathbb{N}$ are named "odd numbers".

The $(n+1)^{\text{th}}$ even number is almost obviously given by the relation:

$$\mathbb{O}: \quad 2n + 1 = \overline{\mathbb{E}} \quad \forall \mathbb{N} \tag{5.2.18}$$

Or more aesthetically:

$$\mathbb{O} = \{x \in \mathbb{N} : \exists n \in \mathbb{N}(x = 2n + 1)\} \tag{5.2.19}$$

Remark

We name "perfect numbers", numbers equal to the sum of their integer divisors strictly smaller than themselves (concept we will see in detail later) such as: $6 = 1 + 2 + 3$ and $28 + 1 = 2 + 4 + 7 + 14$.

What is the sum of the first n odd integers?

Some checks are necessary. The first odd integer is 1. The sum of the first two odd numbers is:

$$1 + 3 = 4 \tag{5.2.20}$$

The sum of the first three odd numbers is:

$$1 + 3 + 5 = 9 \tag{5.2.21}$$

The sum of the first four odd numbers is:

$$1 + 3 + 5 + 7 = 16 \tag{5.2.22}$$

We can think that the sum of the first n odd integers is worth n^2 in other words that:

$$1 + 3 + 5 + \ldots + (2n - 1) = n^2 \tag{5.2.23}$$

Let $\mathrm{P}(n)$ be this relation that we wish to establish for all n.

Let's unfold the three phases of recurrence:

- First phase: the initial verification. It consists of verifying the relation for the first index. Here 1. For $n=1$, in each member of the relation above, we find 1, we can claim that $P(1)$ is true. Note that we have just previously made the verifications at rank $2,3$ and 4.

- Second phase: we establish the hereditary nature of the property (the passage for all n from n to $n+1$). Let the recurrence hypothesis be: «We assume that $P(n)$ is true for a certain rank n». Passage to $n+1$: We demonstrate that the relation is true at rank $n+1$, in other words that:

  $$1+3+5+\ldots+(2n-1)+(2n+1)=(n+1)^2 \qquad (5.2.24)$$

  In the first member we recognize the sum of the first n odd numbers (which is n^2 according to the recurrence hypothesis) to which we have added the $(n+1)$-th odd number $2n+1$. Thus:

  $$1+3+5+\ldots+(2n-1)+(2n+1)=n^2+2n+1 \qquad (5.2.25)$$

  Or:

  $$n^2+2n+1=(n+1)^2 \qquad (5.2.26)$$

- Third phase: The closing clause allows us to take make the summary. By recurrence on n, we have just established that the sum of the first n odd integers is worth n^2.

5.2.2.1.3 Prime Numbers

Definition (#5.2.33): A "prime number" is an integer with exactly two positive divisors (these divisors are both: "1" and the number itself). In the case where there are more than two dividers it is named a "composite number". The property of being prime (or not) is named "primality".

The study of prime numbers is a huge subject in mathematics (see for a small example the section of Number Theory page 352 or of Cryptography page 7216). There are books of thousands of pages on the subject and probable hundreds of research article per month even nowadays. Most theorems are largely out of the study of this book (and out of the interest of its main author...)!

Here is the set of prime numbers less than 1000:

2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, 131, 137, 139, 149, 151, 157, 163, 167, 173, 179, 181, 191, 193, 197, 199, 211, 223, 227, 229, 233, 239, 241, 251, 257, 263, 269, 271, 277, 281, 283, 293, 307, 311, 313, 317, 331, 337, 347, 349, 353, 359, 367, 373, 379, 383, 389, 397, 401, 409, 419, 421, 431, 433, 439, 443, 449, 457, 461, 463, 467, 479, 487, 491, 499, 503, 509, 521, 523, 541, 547, 557, 563, 569, 571, 577, 587, 593, 599, 601, 607, 613, 617, 619, 631, 641, 643, 647, 653, 659, 661, 673, 677, 683, 691, 701, 709, 719, 727, 733, 739, 743, 751, 757, 761, 769, 773, 787, 797, 809, 811, 821, 823, 827, 829, 839, 853, 857, 859, 863, 877, 881, 883, 887, 907, 911, 919, 929, 937, 941, 947, 953, 967, 971, 977, 983, 991, 997

The whole set of prime numbers is sometimes denoted by $\mathbb{P}$.

Remark

Note that the primes numbers set does not include the number "1" because it has a only a single divider (himself) and not two as is the definition.

We can ask ourselves if there are infinitely many prime numbers? The answer is YES and here is a proof (among others) by contradiction.

Proof 5.3.3. Suppose that there is a finite number of prime numbers that would be denoted by:

$$p_1, p_2, \ldots, p_n \tag{5.2.27}$$

We create a new number from the product of this prime number to which we add "1":

$$N = (p_1 p_2 \ldots p_n) + 1 \tag{5.2.28}$$

According to our initial hypothesis and the fundamental theorem of arithmetic (see section Number Theory page 352) the new number N should be divisible by one of the existing prime p_i such that we can write:

$$N = q \cdot p_i \tag{5.2.29}$$

where q is an integer. We can make the division:

$$q = \frac{(p_1 p_2 \ldots p_n) + 1}{p_i} = \frac{p_1 p_2 \ldots p_n}{p_i} + \frac{1}{p_i} \tag{5.2.30}$$

The first term is simplified as p_i is in the product. Let us note the resulting integer E:

$$q = E + \frac{1}{p_i} \tag{5.2.31}$$

But, q and E are integers, so $1/p_i$ should be an integer. But p_i is by definition greater than 1. So $1/p_i$ is not an integer and so is also q.

Then there is contradiction, and we can conclude that the prime numbers are not finite but are infinite.

■ Q.E.D.

Remarks

R1. The product $p_n = p_1 p_2 \ldots p_n$ of the indexed prime numbers $\leq n$ is named the "n-th primorial".

R2. We send the reader to the section Cryptography of the chapter on Theoretical Computing page 7216 (or Number Theory section of the chapter Arithmetic page 365) for the study of some remarkable properties of prime numbers including the famous Euler ϕ function (also named "indicator function") and a 120th-121th century (holocene calendar) industrial application of prime numbers.

5.2.2.2 Relative Integer Numbers

The set of natural integers $\mathbb{N}$ has a few issues that we did not set out earlier. For example, subtracting two numbers into $\mathbb{N}$ does not always have a result in $\mathbb{N}$ (negative numbers not existing in this set). Other issue... dividing two numbers in $\mathbb{N}$ also does not always have a result in $\mathbb{N}$ (fractional numbers - rational or irrational - not existing in this set). We then say in the language of set theory that: the subtraction and division is not an internal operation of $\mathbb{N}$.

We can first resolve the problem of subtraction by adding to the set of natural numbers $\mathbb{N}$, negative integers (revolutionary concept for those who where behind this concept at their time!) to get the set of "relative integers" denoted by $\mathbb{Z}$ (for "Zahl" from German, meaning "Number"):

$$\boxed{\mathbb{Z} = \ldots, -3, -2, -1, 0, 1, 2, 3, \ldots = \{p - q \mid p, q \in \mathbb{N}\}} \tag{5.2.32}$$

The set of natural integers is therefore included in the set of relative integers. This is what we denote by (see section Set Theory page 379):

$$\mathbb{N} \subset \mathbb{Z} \tag{5.2.33}$$

and we have by definition (it is a notations to be learned!!!):

$$\begin{aligned} \mathbb{Z}^+ &= \mathbb{Z}_{>0} = \{n \in \mathbb{Z} | n > 0\} = \mathbb{N}^* \\ \mathbb{Z}_0^+ &= \mathbb{Z}_{\geq 0} = \{n \in \mathbb{Z} | n \geq 0\} = \mathbb{N} \\ \mathbb{Z}_0^- &= \mathbb{Z}_{<0} = \{n \in \mathbb{Z} | n < 0\} \\ \mathbb{Z}^* &= \mathbb{Z}_{\neq 0} = \{n \in \mathbb{Z} | n \neq 0\} \end{aligned} \tag{5.2.34}$$

This set was originally created to make the natural numbers an object that we name a "group" (see section Set Theory page 421) relatively to the addition.

Definition (#5.2.34): We say that a set A is a "countable set", if it is equipotent to $\mathbb{N}$. That is to say if there is a bijection (see section Set Theory page 407) of S on $\mathbb{N}$. Thus, roughly said, two equipotent sets have the same number of elements in the meaning of their cardinal (see section Set Theory page 388), or at least the same infinity.

The purpose of this concept is to understand that the sets $\mathbb{N}$ and $\mathbb{Z}$ are countable.

Proof 5.3.4. Let us show that $\mathbb{Z}$ is countable by writing:

$$x_{2k} = k \quad \text{and} \quad x_{2k+1} = -k - 1 \tag{5.2.35}$$

for any integer $k \geq 0$. This gives the following ordered list:

$$0, -1, 1, -2, 2, -3, 3, \ldots \tag{5.2.36}$$

of all relative integers from natural integers only!

■ Q.E.D.

5.2.2.3 Rational Numbers

The set of relative integers $\mathbb{Z}$ also still has an issue. Dividing two numbers in $\mathbb{Z}$ also does not always have a result in $\mathbb{Z}$ (fraction numbers - rational or irrational - not existing in this set). We then say in the language of set theory that: the division is not an internal operation of $\mathbb{Z}$.

We can thus define a new set that contains all the numbers which can be written as a "fraction" that is to say the ratio of a dividend (numerator) and a divider (denominator). When a number can be written in this form, we say that it is a "fractional number":

$$\text{fraction}:\left\{\frac{2}{3}\right.\begin{array}{l}\swarrow\ \text{Numerator}\\ \longleftarrow\ \text{fraction bar}\\ \nwarrow\ \text{Denominator}\end{array}\tag{5.2.37}$$

A fraction can be used to express a part or fraction of something (of an object, of a distance, of a land, of an amount of money, of a cake...).

To better understand rational number (fractions) let us consider two individuals: Andy and Bobby that bot love pizza. On Monday night, they share a pizza equally. How much of the pizza does each one get? Are you thinking that each boy gets half of the pizza? That's right. There is one whole pizza, evenly divided into two parts, so each boy gets one of the two equal parts. In math, we write $\dfrac{1}{2}$ to mean one out of two parts:

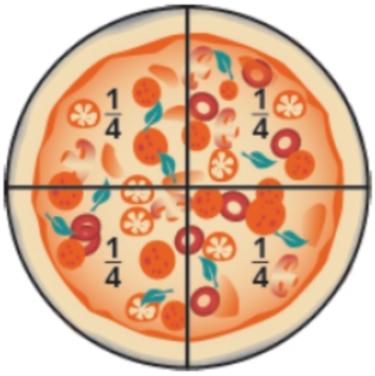

Figure 5.11: **A $1/2$ pizza fraction example (source: OpenStax)**

On Tuesday, Andy and Bobby share a pizza with their parents, Fred and Christy, with each person getting an equal amount of the whole pizza. How much of the pizza does each person get? There is one whole pizza, divided evenly into four equal parts. Each person has one of the four equal parts, so each has $\dfrac{1}{4}$ of the pizza:

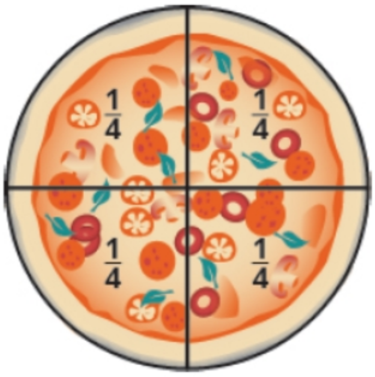

Figure 5.12: **A $1/4$ pizza fraction example (source: OpenStax)**

On Wednesday, the family invites some friends over for a pizza dinner. There are a total of 12 people. If they share the pizza equally, each person would get $\dfrac{1}{12}$ of the pizza:

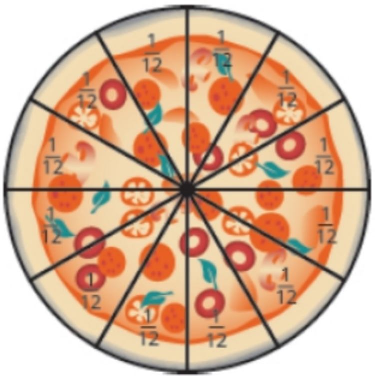

Figure 5.13: **A $1/12$ pizza fraction example (source: OpenStax)**

By definition, the "set of rational numbers" is given by:

$$\boxed{\mathbb{Q}=\left\{\frac{p}{q}|(p,q)\in\mathbb{Z},q\neq 0\right\}} \tag{5.2.38}$$

In other words, any rational number is any number that can be expressed as the quotient or fraction p/q of two integers, p and q, with the denominator q not equal to zero. Since q may be equal to 1, every integer is a rational number.

In the case we put an additional restriction on the denominator such that $q=10^n$ and $n\in\mathbb{N}$ we define therefore the "set of decimal numbers" given by:

$$\boxed{\mathbb{D}=\left\{\frac{p}{10^n}|p\in\mathbb{Z},n\in\mathbb{N}\right\}} \tag{5.2.39}$$

Remark

Pure mathematicians will argue that the definition above is wrong. Yes indeed it is not exact but good enough for engineers and physicists. So here is the right one:

$$\mathbb{Q}=\left\{\frac{p}{q}|(p,q)\in\mathbb{Z},q>0 \text{ and } \gcd(p,q)=1\right\} \tag{5.2.40}$$

Where $q>0$ avoids the division by zero AND the repetition of the sign "$-$" above or below the fraction. We have also added an important property: the greatest common divisor (see section Number Theory page 340) between the both number must be equal to zero. Thus in the purpose that we consider, for example, $3/6$ and $1/2$ are not two distinct numbers. In fact we know that we can always bring a fraction to its irreducible form, where in the latter case we will have $\gcd(p,q)=1$.

We also assume as obvious that:

$$\mathbb{N}\subset\mathbb{Z}\subset\mathbb{D}\subset\mathbb{Q} \tag{5.2.41}$$

The logic of the creation of the set of rational numbers $\mathbb{Q}$ is similar to that of relative integers $\mathbb{Z}$. Indeed, mathematicians wanted to make of the set of relative numbers $\mathbb{Z}$ a "group" with respect to the laws of multiplication and division (see section Set Theory page 308 and page 313).

Moreover, contrary to the intuition of most people, the set of natural integers $\mathbb{N}$ and rational numbers $\mathbb{Q}$ are equipotent (i.e. $\mathbb{Q}\simeq\mathbb{N}$). We can convince ourselves of this equipotence by ranking, as Cantor did, rational numbers in a first time as follows:

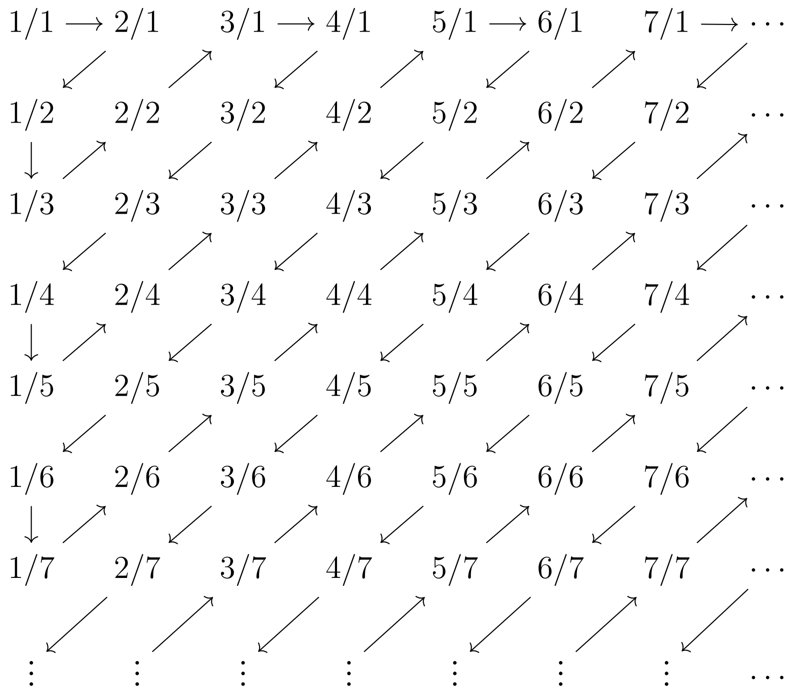

Figure 5.14: **Cantor diagonal method**

This table is constructed so that each rational number appears only once (in the sense of its decimal value) by diagonal hence the name of the method: "Cantor's diagonal".

If we eliminate from each diagonal the rational numbers that appear more than one time (the "equivalent fractions") in order to keep only those who are irreducible (i.e. those with the greatest common divisor of the numerator and denominator is equal to 1), then we can with this distinction define an application $f : \mathbb{N} \Rightarrow \mathbb{Q}$ that is injective (two distinct rational numbers have distinct ranks) and surjective (at any place will be written a rational number).

The application f is therefore bijective: $\mathbb{N}$ and $\mathbb{Q}$ are then effectively equipotent!

The definition a little bit more rigorous (and therefore less funny) of $\mathbb{Q}$ from $\mathbb{Z}$ is as follows (it is interesting to see the notation used):

On the set $\mathbb{Z} \times \mathbb{Z}\ \{0\}$, which should be read as the set constructed from two relative integer whose zero is excluded from the second one, we consider the relation $\mathcal{R}$ between two relative pairs of integers defined by:

$$(a, b)\mathcal{R}(a', b') \Leftrightarrow ab' = a'b \tag{5.2.42}$$

We then easily verify that R is an equivalence relation (see section Operators page 290) on $\mathbb{Z} \times \mathbb{Z} \setminus \{0\}$.

The set of equivalence classes for this relation $\mathcal{R}$ denoted then $(\mathbb{Z} \times \mathbb{Z} \setminus \{0\})\,/\mathcal{R}$ is by definition $\mathbb{Q}$. That is to say that we write therefore more rigorously:

$$\mathbb{Q} = (\mathbb{Z} \times \mathbb{Z} \setminus \{0\})/\mathcal{R} \tag{5.2.43}$$

The equivalence class $(a, b) \in \mathbb{Z} \times \mathbb{Z} \setminus \{0\}$ is explicitly denoted by:

$$\frac{a}{b} \tag{5.2.44}$$

in accordance with the notation that everyone is accustomed to use.

We easily check the addition and multiplication operations that were operations defined on $\mathbb{Z}$ pass without problems to $\mathbb{Q}$ by writing:

$$\frac{a}{b} \cdot \frac{p}{q} = \frac{a \cdot p}{b \cdot q} \quad \text{and} \quad \frac{a}{b} + \frac{p}{q} = \frac{aq + bp}{bq} \tag{5.2.45}$$

Moreover, these operations provide $\mathbb{Q}$ with the structure of a field (see section Set Theory page 429) with $\dfrac{0}{1}$ as neutral element for the addition and $\dfrac{1}{1}$ as neutral element for the multiplication. Thus, any non-zero element of $\mathbb{Q}$ is reversible, in fact:

$$\frac{a}{b} \cdot \frac{b}{a} = \frac{ab}{ab} = \frac{1}{1} \tag{5.2.46}$$

what is written also more technically:

$$(ab, ab)\mathcal{R}(1, 1) \tag{5.2.47}$$

Remark

Even if we want to define $\mathbb{Q}$ as the being the set $\mathbb{Z} \times \mathbb{Z} \setminus 0$ where $\mathbb{Z}$ represents the numerators and $\mathbb{Z} \setminus 0$ the denominators of the rationals, this is not possible because otherwise we would for example $(1,2) \neq (2,4)$ while we expect for an equality.

Hence the need to introduce an equivalence relation which enables us to identify, to return to the previous example, with $(1,2)$ and $(2,4)$. The relation $\mathcal{R}$ that we have defined does not fall from heaven, indeed the reader who handled the rational so far without ever having seen their formal definition knows that:

$$\frac{a}{b}=\frac{a'}{b'} \Leftrightarrow ab'=a'b \tag{5.2.48}$$

It is therefore almost natural to define the relation $\mathcal{R}$ as we have done. In particular, regarding the above example, $\dfrac{1}{2}=\dfrac{2}{4}$ because $(1,2)\mathcal{R}(2,4)$ and the problem is solved.

In addition to the historical circumstances of its establishment, this new entity (set) is distinguished from relative numbers because it induces the original and paradoxical concept of partial quantities. This notion that a priori does not make sense, find its place in the mind of man thanks to the geometry where the idea of fraction of length, of proportion are illustrated more intuitively.

5.2.2.4 Irrational Numbers

It can seem obvious to present irrational numbers before real number (see further below) but this can be explained by the fact that it is the order of the discovering in the human history and therefore it seems more pedagogical to us to present them in this order.

So the set of rational $\mathbb{Q}$ is limited and sadly not sufficient too. Indeed, we may think that all mathematical computation with commonly known operations are reduced to this set but it is not the case!

✍**Examples:**

E1. Let us calculate the square root of two which we denote $\sqrt{2}$ (thing to Pythagorean theorem with a triangle of side 1 and 1 then the third one is of size $\sqrt{2}$). Suppose it is a rational root. So if this is truly a rational, we should be able to express it as a/b, where by the definition of a rational a and b are integers with no common factors. For this reason, a and b can not both be even numbers. There are three remaining possibilities:

1. a is odd (then b is even)
2. a is even (then b is odd)
3. a is odd (then b is odd)

By squaring, we have:

$$\sqrt{2}=\frac{a}{b} \tag{5.2.49}$$

That can be written:

$$2b^2=a^2 \tag{5.2.50}$$

Since the square of an odd number is odd and the square of an even number is even, the case (1) is not possible because a^2 would be odd and $2b^2$ would be even.

If case (2) is also impossible, because then we could write $a=2c$, where c is any integer, and so if we take the square then we have $a^2=4c^2$ that is to say an even number on both sides of equality. Substituting in $2b^2=a^2$ we obtain after simplification that $b^2=2c^2$. Then b^2 would be odd while $2c^2$ would even.

The case (3) is also impossible because a^2 is then odd and $2b^2$ is even (that b is even or odd!).

There is the no solutions! That is to say that the start assumption is false and there does not two integers a and b such that $\sqrt{2}=a/b$.

E2. Let us prove by contradiction, that the famous Euler number e is irrational. To do this, remember that e (see section Functional Analysis page 2289) can also be defined by the Taylor series (see section Sequences and Series page 1703):

$$e=1+\frac{1}{1!}+\frac{1}{2!}+\frac{1}{3!}+\ldots+\frac{1}{n!}+\ldots \tag{5.2.51}$$

Then if e is rational, it could be written in the form p/q (with $q>1$, because we know that is not an integer). Let us multiply both sides of the equality by $q!$:

$$q!e=q!+\frac{q!}{1!}+\frac{q!}{2!}+\frac{q!}{3!}+\ldots+\frac{q!}{q!}+\frac{q!}{(q+1)!}+\frac{q!}{(q+2)!}+\ldots \tag{5.2.52}$$

The first member $q!e$ would then be an integer, because by definition of the factorial:

$$q!=q\cdot(q-1)\cdot(q-2)\ldots2\cdot1 \tag{5.2.53}$$

is an integer.

The first terms of the second member of the previous prior-previous relation, until the term $q!/q!=1$ are also integer because $q!/m!$ is simplified if $q>m$. So by subtraction we find:

$$q!e-\left(q!+\frac{q!}{1!}+\frac{q!}{2!}+\frac{q!}{3!}+\ldots+\frac{q!}{q!}+\ldots\right)=\frac{q!}{(q+1)!}+\frac{q!}{(q+2)!}+\ldots \tag{5.2.54}$$

when the right sequences should be an integer!

After simplification, the second member of the equality becomes:

$$\frac{1}{q+1}+\frac{1}{(q+1)(q+2)}+\ldots \tag{5.2.55}$$

the first term in this sum is strictly less than $1/2$, the second strictly less than $1/4$ second, the third strictly less than $1/8$, etc.

So, since each term is strictly less than the following harmonic series which converges to 1:

$$\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\ldots=1 \tag{5.2.56}$$

then therefore the sequence is not an integer as being strictly less than 1. This is a contradiction!

Thus, the rational numbers do not satisfy the numerical expression of $\sqrt{2}$ and e (to cite only these two particular examples).

They must therefore be complemented by the set of all numbers that can not be written as a fraction (the ratio of an integer dividend and an integer divisor without common factors) and that we name "irrational numbers". Finally we can say that:

Definition (#5.2.35): In mathematics, an "irrational number" is any real number that cannot be expressed as a ratio of integers. Irrational numbers cannot be represented as terminating or repeating decimals.

5.2.2.5 Real Numbers

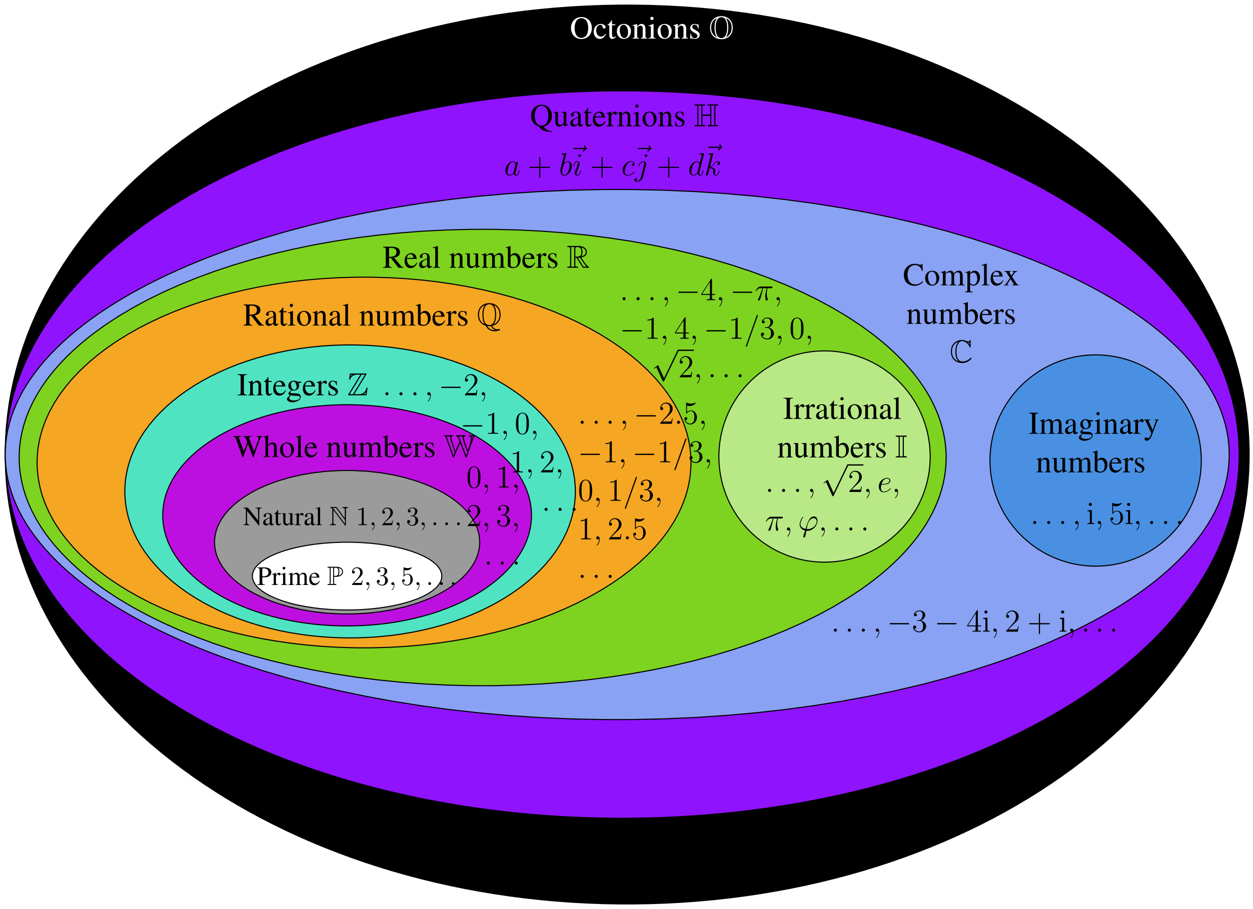
Definition (#5.2.36): The union of rational and irrational numbers gives the set of "real numbers" that we denote by:

$$\mathbb{Q} \subset \mathbb{R} \tag{5.2.57}$$

Remark

Mathematicians in their usual rigour have different techniques to define real numbers. They use the properties of topology (among others) and especially Cauchy sequences but that's another story that goes beyond the formal scope of this section. For a "set point of view" definition of ℝ (the real numbers are often described as "the complete ordered field") the reader should report to the section on Set Theory page 429.

Below we can see a figure of most common sets of numbers (notice that the decimal set 𝔻 is omitted as it is taught mainly only in France):



Octonions 𝕆
Quaternions ℍ
$a+b\vec{i}+c\vec{j}+d\vec{k}$
Real numbers ℝ
$\ldots,-4,-\pi,$
$-1,4,-1/3,0,$
$\sqrt{2},\ldots$
Complex numbers ℂ
Rational numbers ℚ
Integers ℤ $\ldots,-2,$
$-1,0,$
$1,2,$
$\ldots$
Whole numbers 𝕎
$0,1,$
$2,3,$
$\ldots$
Natural ℕ $1,2,3,\ldots$
Prime ℙ $2,3,5,\ldots$
$\ldots,-2.5,$
$-1,-1/3,$
$0,1/3,$
$1,2.5$
$\ldots$
Irrational numbers 𝕀
$\ldots,\sqrt{2},e,$
$\pi,\varphi,\ldots$
Imaginary numbers
$\ldots,\mathrm{i},5\mathrm{i},\ldots$
$\ldots,-3-4\mathrm{i},2+\mathrm{i},\ldots$

Figure 5.15: **Simple numbers sets summary (transcendent and algebraic numbers are not represented)**

Obviously we are led to ask ourselves whether ℝ is countable or not. In other words: can pure science - i.e. mathematics - quantify the unquantifiable? The answer and the proof is quite simple.

Proof 5.3.5. By definition, we have seen above that there must be a bijective correspondence between $\mathbb{Q}$ and $\mathbb{R}$ to that $\mathbb{R}$ is countable.

For simplicity, we will show that the interval $[0, 1[$ is then not countable. This will involve of course by extension that $\mathbb{R}$ is not countable!

The elements of this interval are represented by infinite sequences between 0 and 9 (in the decimal system):

- Some of these suites are zero from starting from a given rank, some not.
- So we can identify $[0, 1[$ to the set of all sequences (finite or infinite) of integers between 0 and 9.

$n°1$	x_{11}	x_{12}	x_{13}	x_{14}	$\cdots$	x_{1p}	$\cdots$
$n°2$	x_{21}	x_{22}	x_{23}	x_{24}	$\cdots$	x_{2p}	$\cdots$
$n°3$	x_{31}	x_{32}	x_{33}	x_{34}	$\cdots$	x_{3p}	$\cdots$
$n°4$	x_{41}	x_{42}	x_{43}	x_{44}	$\cdots$	x_{4p}	$\cdots$
$n°5$	x_{51}	x_{52}	x_{53}	x_{54}	$\cdots$	x_{5p}	$\cdots$
$n°6$	x_{61}	x_{62}	x_{63}	x_{64}	$\cdots$	x_{6p}	$\cdots$
	$\cdots$						
		$\cdots$					
			$\cdots$				
$n°k$	x_{k1}	x_{k2}	x_{k3}	x_{k4}	$\cdots$	x_{kp}	$\cdots$
						$\cdots$	

If this set was countable, we could classify these sequences (with a first, second, etc.). Thus, the sequence $x_{11}x_{12}x_{13}x_{14}\ldots x_{1p}\ldots$ would be classified first and so on ... as proposed in the above table.

We could then edit this infinite matrix as follows: to each element of the diagonal, we add 1, according to the rule: $0 + 1 = 1, 1 + 1 = 2, 8 + 1 = 9$ and $9 + 1 = 0$:

$n°1$	$x_{11}+1$	x_{12}	x_{13}	x_{14}	$\cdots$	x_{1p}	$\cdots$
$n°2$	x_{21}	$x_{22}+1$	x_{23}	x_{24}	$\cdots$	x_{2p}	$\cdots$
$n°3$	x_{31}	x_{32}	$x_{33}+1$	x_{34}	$\cdots$	x_{3p}	$\cdots$
$n°4$	x_{41}	x_{42}	x_{43}	$x_{44}+1$	$\cdots$	x_{4p}	$\cdots$
$n°5$	x_{51}	x_{52}	x_{53}	x_{54}	$\cdots$	x_{5p}	$\cdots$
$n°6$	x_{61}	x_{62}	x_{63}	x_{64}	$\cdots$	x_{6p}	$\cdots$
	$\cdots$						
		$\cdots$					
			$\cdots$				
$n°k$	x_{k1}	x_{k2}	x_{k3}	x_{k4}	$\cdots$	x_{kp}	$\cdots$
						$\cdots$	

Then let us consider the sequence on the diagonal:

- It cannot be equal to the first sequence of the first row in the prior-previous table since it is distinguished at least by the first element.

- It cannot be equal to the second sequence of the second row of the prior-previous table since is distinguished at least by the second element.
- It cannot be equal to the third sequence of the second row of the prior-previous table since is distinguished at least by the third element.

and so on ... It the cannot be equal to any of the sequences in this table!

So whatever the chosen classification of infinite sequences of $0 \ldots 9$, there is always one who escapes this classification! So it is that it is impossible to number them ... simply because they do not form a countable set (i.e. $\mathbb{R} \not\approx \mathbb{N}$)!

■ Q.E.D.

The technique that has allowed us to achieve this result is known as the "Cantor diagonal process" (because similar to that used for equipotence between the natural and rational set) and the set of real numbers is said to have the "power of the continuum" by the fact that it is uncountable.

We may assume that it is intuitive for the reader that any real number can be approximated infinitely close by a rational number (for irrational numbers we simply stop at a given number of decimals and find the corresponding rational). Mathematicians say therefore that $\mathbb{Q}$ is "dense" in $\mathbb{R}$ and denote this by:

$$\bar{\mathbb{Q}} = \mathbb{R} \qquad (5.2.58)$$

To see this (in the mathematician way of life...) let us take a real number x. For any $n \in \mathbb{N}$ we denote by:

$$p_n = [10^n x] \qquad (5.2.59)$$

the integer part of x that was previously multiplied by 10^n.

By definition of the integer part of a real number, we have:

$$p_n \leq 10^n x < p_n + 1 \qquad (5.2.60)$$

This inequality is equivalent to:

$$\frac{[10^n x]}{10^n} \leq x < \frac{[10^n x] + 1}{10^n} \qquad (5.2.61)$$

Let us put for all $n \in \mathbb{N}$:

$$a_n = \frac{[10^n x]}{10^n} \qquad \text{and} \qquad b_n \frac{[10^n x] + 1}{10^n} \qquad (5.2.62)$$

where a_n and b_n are respectively the approached decimal values to $x \cdot 10^{-n}$ by default or by excess.

Notice that $\forall n \in \mathbb{N}$ we have:

$$b_n - a_n = 10^{-n} \qquad (5.2.63)$$

and that $\forall n \in \mathbb{N}$ we have $\{a_n, b_n\} \in \mathbb{Q}$.

✍**Example:**

We want to calculate $\sqrt{2}$. Then:

n		a_n	b_n	error
1	$1 < \sqrt{2} < 2$	1	2	1
2	$1.4 < \sqrt{2} < 1.5$	1.4	1.5	0.1
3	$1.41 < \sqrt{2} < 1.42$	1.41	1.42	0.01
4	$1.414 < \sqrt{2} < 1.415$	1.414	1.415	0.001

Theorem 5.4. If the sequences (a_n) and (b_n) are adjacents, that is to say that (a_n) is ascending and (b_n) descending then we have:

$$b_n - a_n \xrightarrow[k\to\infty]{} 0 \tag{5.2.64}$$

Proof 5.4.1. Given $n \in \mathbb{N}$, let us recall that:

$$p_n \leq 10^n x < p_n + 1 \tag{5.2.65}$$

where $p_n = [10^n x]$. Let us multiply both sides by 10 then we get:

$$10p_n \leq 10^{n+1}x < 10(p_n + 1) \tag{5.2.66}$$

Then:

- We have quite obviously:

  $$10p_n \leq p_{n+1} \tag{5.2.67}$$

  hence:

  $$\frac{p_n}{10^n} \leq \frac{p_{n+1}}{10^{n+1}} \tag{5.2.68}$$

  and therefore $a_n \leq a_{n+1}$. The sequence (a_n) is therefore ascending.

- And we also have quite obviously:

  $$1 + p_{n+1} < 10p_{n+1} \tag{5.2.69}$$

  hence:

  $$\frac{1 + p_{n+1}}{10^{n+1}} \leq \frac{p_{n+1}}{10^n} \tag{5.2.70}$$

  and therefore $b_{n+1} \leq b_n$. The sequence (b_n) is therefore descending.

As:

$$b_n - a_n = 10^{-n} \tag{5.2.71}$$

We have indeed:

$$b_n - a_n \underset{k\to\infty}{\longrightarrow} 0 \tag{5.2.72}$$

and therefore we have proved that the both sequences (a_n) and (b_n) are adjacents. They are convergent and converge both to a same limit $L \in \mathbb{R}$.

As $\forall n \in \mathbb{N}$:

$$p_n \leq 10^n x < p_n + 1 \tag{5.2.73}$$

We have necessarily $L = x$.

■ Q.E.D.

Corollary 5.4.1. An real number is a limit of a sequence of rational numbers.

Proof 5.4.2. This is an immediate consequence of the previous theorem. Indeed, the sequences (a_n) and (b_n) are sequences of rationals.

■ Q.E.D.

5.2.2.5.1 Percentages

In business[13] (but not only obviously!) it is of usage with real numbers to communicate in percentages or per-thousand when we have to deal with ratios.

Definitions (#5.2.37):

D1. Given a scalar $x \in \mathbb{R}$ then expressed in "percentage" it will be denoted by:

$$x\% = x \cdot 100 \tag{5.2.74}$$

D2. Given a scalar $x \in \mathbb{R}$ then expressed in "per-thousand" it will be denoted by:

$$x‰ = x \cdot 1,000 \tag{5.2.75}$$

✍**Examples:**

E1. The scalar 0.5 expressed in percentage is given by:

$$0.5 \cdot 100 = 50\%$$

E2. The scalar 1 expressed in percentage is given by:

$$1 \cdot 100 = 100\%$$

E3. The percentage 75% expressed as a scalar is given by:

$$\frac{75}{100} = 0.75$$

---

[13] For interest rates, discounts, bonus, etc.

But we also have another well known percentage...:

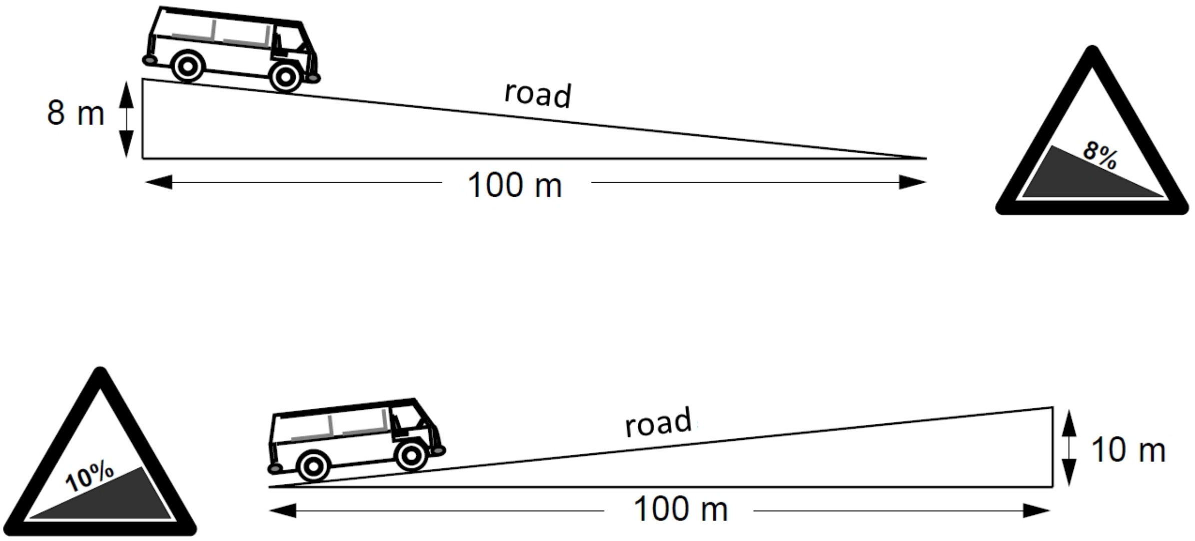


Figure 5.16: **Percentage usage illustration**

Remark

Notice something funny about percentages! We have:

$$x\% \text{ of } y = y\% \text{ of } x$$

That's simply because:

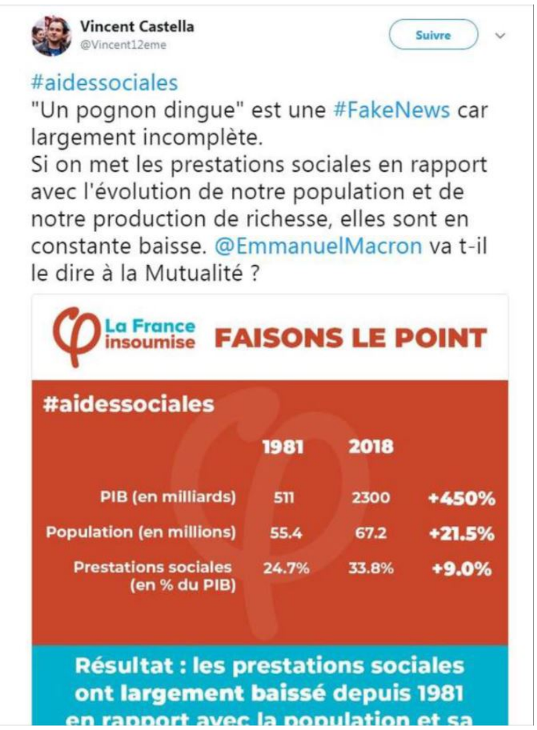
$$y\frac{x}{100} = x\frac{y}{100} \tag{5.2.76}$$

So, in order to calculate a percentage in your head you might want to turn it around: What's 2% of 50? It's 50% of 2.

You must be especially carefully when manipulating percentages (that are relative values for recall!) and even more when you compare that to absolute values. A famous recent "fake news" (in June 12018 according to holocene calendar) made by a socialist activist (supposing to be graduate in engineering...) in France on Twitter (a social media well-known for its fake news) made a lot of people laugh... but at the same time a huge number of people believed that the "fact" was true[14]. Here is the communication (try to guess where is the error, and notice that the author of the post says that France government communicates "fake news" but in reality... he is the guy who communicated the "fake news"... LoL):

---

[14] Serious newspapers, like *Le Monde*, also relayed the information as obviously wrong



Vincent Castella
@Vincent12eme

#aidessociales
"Un pognon dingue" est une #FakeNews car largement incomplète.
Si on met les prestations sociales en rapport avec l'évolution de notre population et de notre production de richesse, elles sont en constante baisse. @EmmanuelMacron va t-il le dire à la Mutualité ?

La France insoumise **FAISONS LE POINT**

#aidessociales

	1981	2018	
PIB (en milliards)	511	2300	+450%
Population (en millions)	55.4	67.2	+21.5%
Prestations sociales (en % du PIB)	24.7%	33.8%	+9.0%

Résultat : les prestations sociales ont largement baissé depuis 1981 en rapport avec la population et sa

Ok let us check if really the government welfare has indeed decrease in France while the population and the Gross Domestic Product (GDP) has at the same time increased as the author of this Tweet argue...

First we have (if we do the calculations correctly):

$$\text{Increase of GDP} = \frac{2300 - 511}{511} \cdot 100 \cong +350.1\% \qquad (5.2.77)$$

Secondly:

$$\text{Increase of Population} = \frac{67.2 - 55.4}{55.4} \cdot 100 \cong +21.3\% \qquad (5.2.78)$$

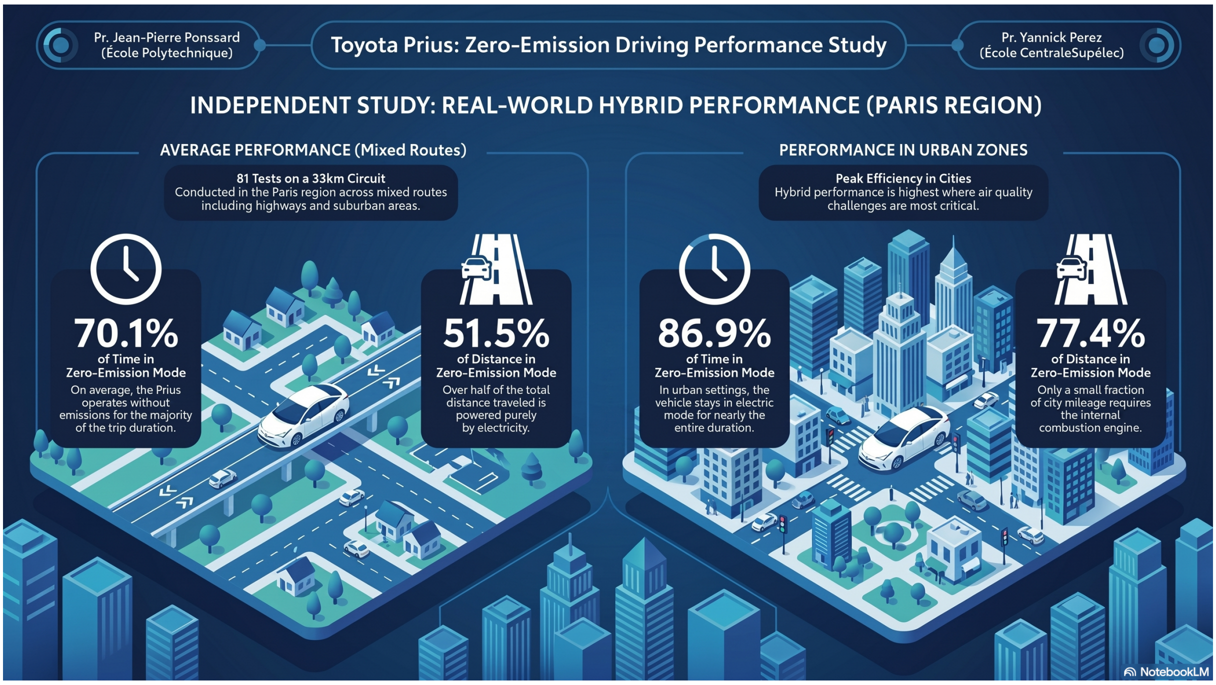
Finally:

$$\text{Increase social welfare} = \frac{33.8 - 24.7}{24.7} \cdot 100 \cong +36.84\% \qquad (5.2.79)$$

You see the error now...? The author of the tweet calculates for the welfare the increase in what we name in finance "basis points", and not in "percentages" as he does for the two firsts. This a very nice example on how to use statistics to lie... (lies works only with scientific illiterate people obviously!).

We don't need to say that this "tweet" was removed a few days after by his author from Twitter...

Another interesting example of pseudo-deception with percentages is the case of Toyota, which communicated the performance of its cars in electric mode in terms of time rather than distance. An independent study has shown afterward that in reality:



Pr. Jean-Pierre Ponssard (École Polytechnique)

Toyota Prius: Zero-Emission Driving Performance Study

Pr. Yannick Perez (École CentraleSupélec)

INDEPENDENT STUDY: REAL-WORLD HYBRID PERFORMANCE (PARIS REGION)

AVERAGE PERFORMANCE (Mixed Routes)

81 Tests on a 33km Circuit
Conducted in the Paris region across mixed routes including highways and suburban areas.

70.1% of Time in Zero-Emission Mode
On average, the Prius operates without emissions for the majority of the trip duration.

51.5% of Distance in Zero-Emission Mode
Over half of the total distance traveled is powered purely by electricity.

PERFORMANCE IN URBAN ZONES

Peak Efficiency in Cities
Hybrid performance is highest where air quality challenges are most critical.

86.9% of Time in Zero-Emission Mode
In urban settings, the vehicle stays in electric mode for nearly the entire duration.

77.4% of Distance in Zero-Emission Mode
Only a small fraction of city mileage requires the internal combustion engine.

You must also be extremely careful relatively to mass-media scientific communications (and even more on social networks...) when you read something like « ... *product X increase deadly syndrome Y of* 400%... ». Because sometimes, the increase could be (random example) in fact of 2 individual on $100,000$ to 8 individuals (still on $100,000$ obviously!). This is a way to bias our brain associating huge percentage to quantities of small magnitudes... So in such situations always look for the original absolute values and to corresponding the risk ratio (see section Numerical Methods page 6503).

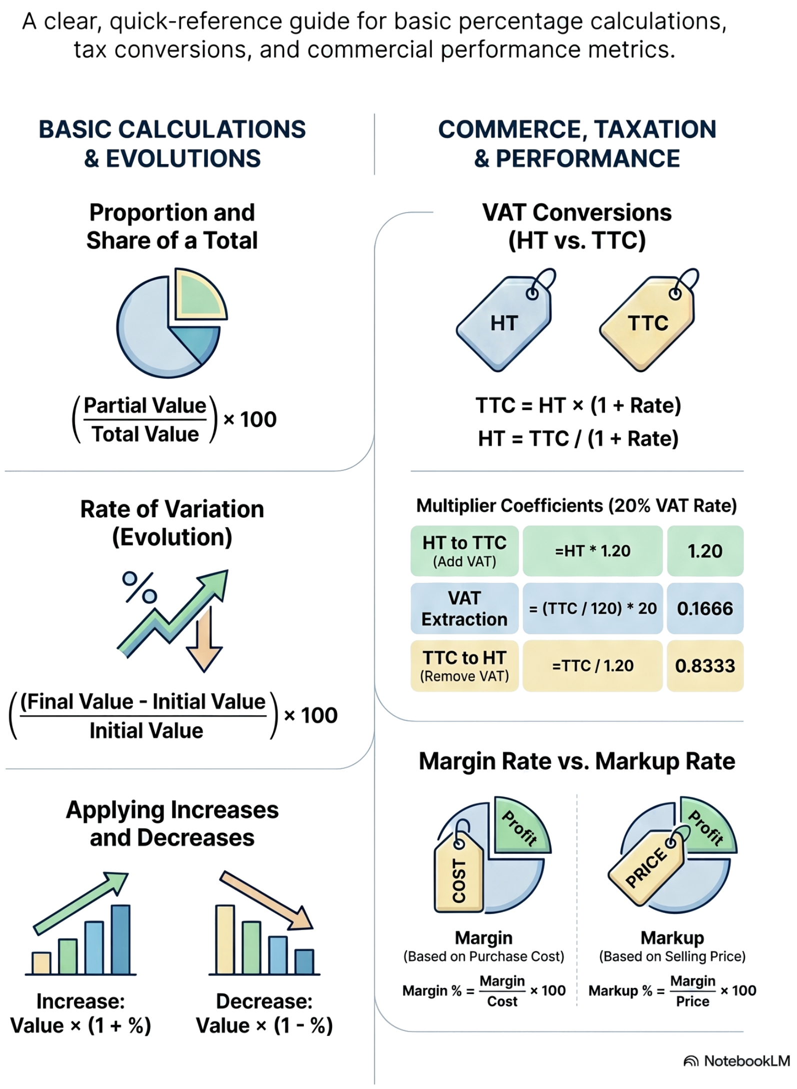
Another famous academic example on how tricky the manipulation of percentages can be is the so named "potato paradox". The paradox is stated as: «*You have* 100 *[kg] of potatoes, which are* 99% *water by weight. You let them dehydrate until they're* 98% *water. How much do they weight now?*» The result using algebra is that after evaporating of the water, the remaining total quantity, x, contains 1 [kg] of pure potatoes and $(98/100)x$ of water. The relation becomes:

$$1+\frac{98}{100} \Rightarrow 1=\frac{1}{50}x \tag{5.2.80}$$

resulting in $x=50$ [kg].

A last one used by some dishonest politicians, managers and marketing specialists is to say that an economic indicator that should be with a high value had increased of $X\%$ a few years before, and that now thanks to them it has decrease also of the same percentage $X\%$ and that we fall back then on the same value as before and like this nothing has changed! But we let the reader check if $C_0(1+X\%)(1-X\%)=C_0$ or not....

Here below is a summary of the most basic well known percentage calculations that any people having a family or any worker will use hundred of even thousands of times in its life:



A clear, quick-reference guide for basic percentage calculations, tax conversions, and commercial performance metrics.

BASIC CALCULATIONS & EVOLUTIONS
Proportion and Share of a Total
(Partial Value / Total Value) × 100
Rate of Variation (Evolution)
%
((Final Value - Initial Value) / Initial Value) × 100
Applying Increases and Decreases
Increase: Value × (1 + %)
Decrease: Value × (1 - %)
COMMERCE, TAXATION & PERFORMANCE
VAT Conversions (HT vs. TTC)
HT
TTC
TTC = HT × (1 + Rate)
HT = TTC / (1 + Rate)
Margin Rate vs. Markup Rate

PRICE
Profit
Margin
(Based on Purchase Cost)
Margin % = Margin / Cost × 100
Markup
(Based on Selling Price)
Markup % = Margin / Price × 100
NotebookLM

Multiplier Coefficients (20% VAT Rate)

HT to TTC (Add VAT)	=HT * 1.20	1.20
VAT Extraction	= (TTC / 120) * 20	0.1666
TTC to HT (Remove VAT)	=TTC / 1.20	0.8333

Also keep in mind that in practice it is frequent to normalize a series of values $x_1, \ldots, x_n$ with $x_i \in \mathbb{R}$ (considered as a vector $\vec{x}$) into percentages, such that $x_{p,i} \in [0, 1]$ using the simple obvious following transformation[15] named a "Min-Max scaling":

$$\boxed{x_{p,i} = \frac{x_i - \min(\vec{x})}{\max(\vec{x}) - \min(\vec{x})}} \tag{5.2.81}$$

This is especially well known in spreadsheet software like Microsoft® Excel® when using Normalized bar charts, or normalized key performance indicators (conditional formatting), or also in Data Science where plenty of other transformations (see page 6772) are made for the use of some neural networks algorithms for example.

---

[15] The reader must avoid the confusion between "normalizing a variable" and "center reducing a random variable (i.e. standardizing)" to make it a $Z = \mathcal{N}(0, 1)$ statistical variable as we will see further below!

Transformation	Use Case	Equation / Calculation Method
Log Transformation	Stabilizing variance, normalizing data, useful for data with exponential changes (e.g., economic data).	$y = \log(x)$
Square Root Transformation	Stabilizing variance, normalizing data, suitable for data sets with non-negative values (counts, areas).	$y = \sqrt{x}$
Box-Cox Transformation	Generalized form for stabilizing variance, making data more normal-like, applicable in various scenarios.	$y(\lambda) = \frac{x^\lambda - 1}{\lambda}$ for $x > 0$ and $\lambda \neq 0$
Z-Score/Standard Score	Standardizing data to have mean of 0 and standard deviation of 1, used in outlier detection and normalization.	$z = \frac{x-\mu}{\sigma}$
Min-Max Scaling	Scaling data to a fixed range $(0$-$1)$, useful in scale-sensitive algorithms (neural networks, k-NN).	$X_{\text{scaled}} = \frac{X - X_{\min}}{X_{\max} - X_{\min}}$
Normalization (L1, L2 norms)	Scaling individual samples, essential for algorithms needing comparable scales (support vector machines).	$\lVert\vec{x}\rVert_2 = \sqrt{\sum_{i=1}^{n} \lvert x_i \rvert^2}$
Difference Transformation	Making time-series data stationary by subtracting previous observation from the current one.	$\Delta x_t = x_t - x_{t-1}$
Categorical Encoding	Converting categorical data into a numeric format for use in mathematical models (One-Hot, Label Encoding).	One-Hot: Binary vectors, Label: Integer encoding
Binning/Discretization	Transforming continuous variables into discrete bins, simplifying complex relationships in data.	Interval: Equal-Width Quantile: Equal Frequency Count Tree-Based: Decision Tree
...	...	...

Table 5.16: **Some well known basic variables transformations**

5.2.2.6 Transfinite Numbers

We now are with an infinity of real numbers which is different from that of natural numbers. Cantor then dared what no one had dared since Aristotle: the positive integers sequence is also infinite, the set $\mathbb{N}$, is then a set that has a countable infinity of elements, then he said that the cardinal (see section Set Theory page 388) of this set was a number that existed as such, without that we need to use the tote symbol ∞, he denoted it:

$$\aleph_0 = \text{Card}(\mathbb{N}) \tag{5.2.82}$$

This symbol is as we know (see section Set Theory page 390) the first letter of the Hebrew alphabet, pronounced "aleph zero". Cantor was going to name this strange number, a "transfinite number".

The decisive act is to assert that there is, after the finite, a transfinite, that is to say an unlimited scale of determined modes which by nature are infinite, and yet can be specified, as for the finite, by specific numbers, well defined and distinguishable from each other!! This tool was necessary as a set cardinal can be equal to one of its parts as we will see just below!

After this first stroke going against most ideas for over two thousand years, Cantor would continue its path and build the calculation rules, paradoxical at first glance, of the transfinite numbers. These rules were based, as we said earlier, on the fact that two infinite sets are equivalent if there exists a bijection between the two sets.

Thus, we can easily show that the infinity of even numbers is equivalent to the infinity of integers: for this, it suffices to show that for every integer, we can associate an even number, his double, and vice versa. Therefore the cardinal of integers is equal to those of even numbers (the cardinal of a set can be equal to one of its parts!).

Thus, although if even numbers are included in the set of integers, there is an infinity α_0 of them, the two sets are equipotent. By stating that a set can be equal to one of its parts, Cantor goes against what seemed obvious to Aristotle and Euclid: the set of all sets is infinite! This will shake the whole of mathematics and will bring the Zermelo-Fraenkel axiomatic that we will see in the section of Set Theory at page 382.

From the above, Cantor define the following calculations rules on the cardinals:

$$\boxed{\aleph_0+1=\aleph_0 \qquad \aleph_0+\aleph_0=\aleph_0 \qquad \aleph_0^2=\aleph_0} \tag{5.2.83}$$

At first glance these rules seem non-intuitive, but in fact they are! Indeed, Cantor defined the addition of two transfinite numbers as cardinal of the disjoint union of the corresponding sets.

✍**Examples:**

E1. By denoting $\aleph_0$ the cardinal of $\mathbb{N}$ we have $\aleph_0+\aleph_0$ which is equivalent to saying that we sum the cardinal of $\mathbb{N}$ disjoint union $\mathbb{N}$. But as $\mathbb{N}$ disjoint union $\mathbb{N}$ is equipotent to $\mathbb{N}$ then $\aleph_0+\aleph_0=\aleph_0$ (it is enough to be convinced to take the set of odd and even integers which are both countable and which disjoint union is also countable).

E2. Other trivial example: $\aleph_0+1$ corresponds to the cardinality of $\mathbb{N}$ union a point. This set is still equipotent to $\mathbb{N}$ therefore $\aleph_0+1=\aleph_0$.

We will also during our study of the section Set Theory (page 391) that the concept of Cartesian product of two countable sets is such that we have:

$$\text{Card}(\mathbb{N}\times\mathbb{N})=\text{Card}(\mathbb{N}^2)=[\text{Card}(\mathbb{N})]^2 \tag{5.2.84}$$

and therefore:

$$\aleph_0^2=\aleph_0 \tag{5.2.85}$$

Similarly (see section Set Theory page 383) since $\mathbb{Z}=\mathbb{Z}^+\cup\mathbb{Z}^-$ we have:

$$\aleph_0+\aleph_0=\aleph_0 \tag{5.2.86}$$

and identifying $\mathbb{Q}$ to $\mathbb{Z}\times\mathbb{Z}$ (ratio of a numerator over denominator) we have immediately:

$$\aleph_0\times\aleph_0=(\aleph_0)^2=\aleph_0 \tag{5.2.87}$$

We can also prove an interesting statement: if we consider the cardinality of the set of all the cardinals, it is necessarily greater than all the cardinals, including itself (it is better to have read previously the section of Set Theory page 378)! In other words: the cardinality of the set of all sets of A is greater than the cardinal of A itself.

This implies that there is no set containing all sets since there is always a bigger one (it is an equivalent form of the famous old Cantor's paradox)!!!

In technical language it means considering a non-empty set A and then to state that:

$$\text{Card}(A)\leq\text{Card}(\mathcal{P}(A)) \tag{5.2.88}$$

where $\mathcal{P}(A)$ is the set of subsets of A.

That is to say, by definition of the order relation $<$ (strictly less), it suffices to prove that there is no surjective application $f:A\mapsto\mathcal{P}(A)$, in other words that to each element of the set of parts of A it does not match at least one pre-image in A.

Remark

The set $\mathcal{P}(\mathbb{N})$ for example consists of the set of even numbers, odd numbers, natural numbers, as well as the empty set itself, etc. $\mathcal{P}(\mathbb{N})$ is therefore the set of all "potatoes" (to borrow the vocabulary of high school ...) that make $\mathbb{N}$.

Proof 5.4.3. Suppose that we can number each potato of $\mathcal{P}(A)$ with at least one element of A (imagine that with $\mathbb{N}$). In other words it is equivalent to suppose that $f : A \mapsto \mathcal{P}(A)$ is surjective and let us consider a subset E of A such that:

$$E = \{x \in A | x \notin f(x)\} \tag{5.2.89}$$

that is to say the set of elements x of A that do not belong to the set numbered by x (the element x does not belong to the "potato" that it numbers in other terms...).

Or, if f is surjective it must also be a $y \in A$ for this subset E such that:

$$f(y) = E = \{x \in A | x \notin f(x)\} \tag{5.2.90}$$

since E is also a subset of A.

Suppose that y belongs to E. In this case, by definition of E, $y \notin f(y) = E$ (by definition of E that applies for every x and x can also be obviously y or z or doesn't matter what). By consequence, $y \notin E$, but in this second case, always by definition of E, $y \in f(y) = E$ (as y is not in E). We see therefore that the element y cannot exists and therefore f cannot be surjective.

We strongly recommend the reader to review the previous sentence more than on time if necessary.

■ Q.E.D.

Remark

David Hilbert famously argued that infinity cannot exist in physical reality. The consequence of this statement still under debate today. However... infinity has countless practical applications! Here's one way to think about it: do negative numbers have any practical applications? I mean you can't really have a negative amount of anything, can you? You can't have negative five apples! But negative number are useful in accounting! You can also take limits of functions as the variable goes to infinity. In this way you can calculate things like terminal velocity and escape velocity and many others! Infinity can be kinda observed as the more distant an object is the more the light it emits will be red-shifted, i.e. the wavelength tends to infinity as the object approach the Hubble sphere horizon (or maybe one day in the future we will be able to observe an object entering the horizon of a Black Hole where the same kind of effect occurs).

Engineers consider infinity ∞ just a being what is too big for being measurable. As illustrated on the graduation (top left corner) of the multimeter below:

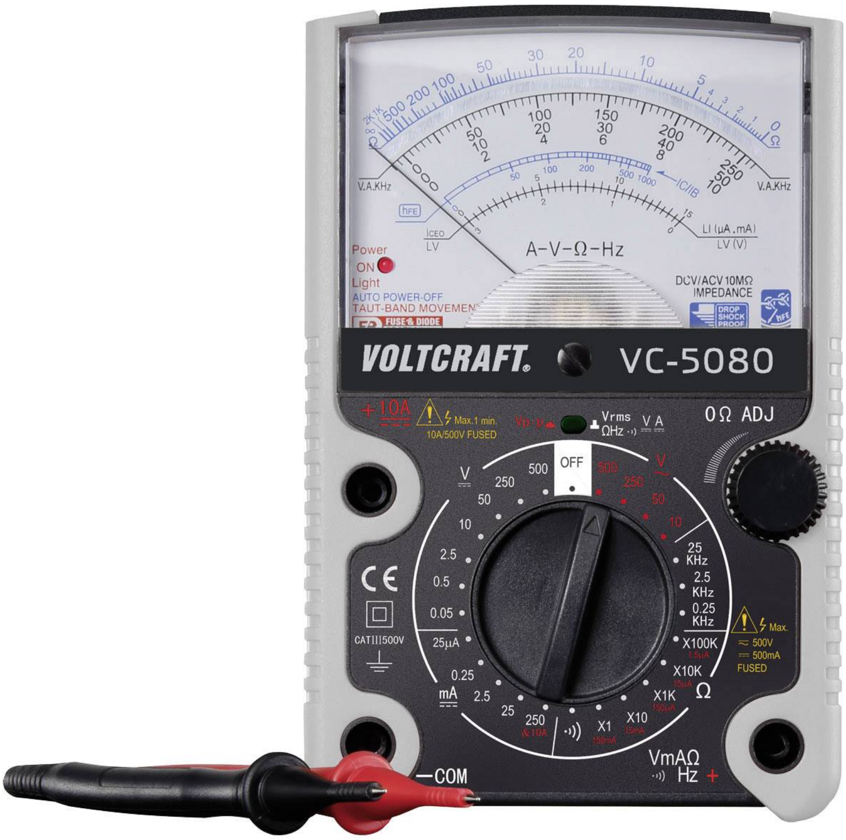

Figure 5.17: **VOLTCRAFT VC-5080 Multimeter with ohmic graduation displaying ∞ symbol**

5.2.2.7 Complex Numbers

Invented in the 116th century (holocene calendar) among others by Girolamo Cardano and Rafaello Bombelli, "complex numbers" (also named "imaginary numbers") are used to solve problems with no solutions in $\mathbb{R}$ and also used to mathematically formalize certain transformations in the plan such as rotation, similarity, translation, etc. and also to generalized some theorem restricted to $\mathbb{R}$ and therefore hiding some interesting results for practical engineering. For physicists, complex numbers above are also a very convenient way to simplify notations. It is thus very difficult to study wave phenomena, General Relativity or quantum mechanics without using complex numbers and expressions.

The importance and utility of complex numbers in biology, cosmology, physics, astrophysics, electronics, electromechanics, astrophysics, microelectronics, electrical engineering, statistics, optics, mechanical engineering, fluid mechanics etc. are almost never questioned by students and professionals as they appear very quickly in the corresponding courses (most of times just after thirty to fifty hours) or textbooks. However a significant percentage of students and professional in Finance and Insurance question the utility of complex numbers as their application cases appear in the fields most of the time only at the postgraduate level (PhD). So here is a small non exhaustive list of topics in Finance and Insurance where complex numbers appear and are really useful (most of the topics below are treated in the present book):

- In Fourier transforms for solving nonlinear partial differential equations (Black-Sholes for example)
- In Laplace transforms for solving nonlinear partial differential equations (Heston model)
- In Fourier transforms for spectral analysis of time series
- In solving polynomials of auto-regressive time series models
- In the use of the characteristic function in the CreditRisk First Boston model
- In PCA (Principal Component Analysis) analysis when IEEE rounding errors with `R` and Python™ produce complex eigenvalues

There are several ways to construct complex numbers. The first is typical of the construction way that mathematicians used as part of Set Theory. They define a couple of real numbers and define the operations between these couples to finally arrive at a meaning of the complex number concept. The second one is less rigorous but its approach is simpler and consist to define the pure unit imaginary number i and then build arithmetic operations from its definition. We will opt for the second method in the texts that will follow!

Definitions (#5.2.38):

D1. We define the "unit pure imaginary number" that we denote by i by the following property:

$$\boxed{\mathrm{i}^2=-1 \Leftrightarrow \mathrm{i}=\sqrt{-1}} \tag{5.2.91}$$

D2. A "complex number" is a pair of a real number a and an imaginary number $\mathrm{i}b$ and generally written in the following form:

$$\boxed{z = a + \mathrm{i}b} \tag{5.2.92}$$

where a and b are numbers belonging to $\mathbb{R}$.

D3. We note the set of complex numbers by $\mathbb{C}$ and therefore we have by construction:

$$\mathbb{R} \subset \mathbb{C} \tag{5.2.93}$$

Remark

The set $\mathbb{C}$ is identified to the oriented Euclidean plane E (see section Vector Calculus page 1830) thanks to the choice of a direct orthonormal basis (we therefore get the "Argand-Cauchy plane", also named "Gauss-Argand plane" or more commonly "Gauss plane" that we will see a little further below and that seems have be defined for the first time in 11806 according to holocene calendar).

The set of complex numbers that constitutes a field (see section Set Theory page 429) and denoted by $\mathbb{C}$, is defined (in a simple way to start) in the notation of set theory by:

$$\boxed{\mathbb{C} = \{z = (x + \mathrm{i}y) | x, y \in \mathbb{R}\}} \tag{5.2.94}$$

In other words we say that the field $\mathbb{C}$ is the field $\mathbb{R}$ to which we have added the imaginary number i. Which is formally denoted by:

$$\mathbb{R}[\mathrm{i}] \tag{5.2.95}$$

The addition and multiplication of complex numbers are internal operations to the set (field) of complex numbers (we will come back much more in detail on certain properties of complex numbers in the section of Set Theory page 421) and defined by:

$$\begin{aligned} z_1 + z_2 &= (x_1 + x_2) + \mathrm{i}(y_1 + y_2) \\ z_1 \cdot z_2 &= (x_1 x_2 - y_1 y_2) + \mathrm{i}(x_1 y_2 + x_2 y_1) \end{aligned} \tag{5.2.96}$$

The "real part" of z is traditionally denoted by:

$$\Re(z) = x \tag{5.2.97}$$

The "imaginary part" of z is traditionally denoted by:

$$\Im(z) = x \tag{5.2.98}$$

The "conjugate" of z is defined by:

$$\bar{z} = \overline{x + \mathrm{i}y} = x - \mathrm{i}y \tag{5.2.99}$$

and is sometimes also denoted z^* (particularly in quantum physics in some books!).

From a complex and its conjugate, it is possible to find its real and imaginary parts. These are the following obvious relations:

$$\Re(z) = \frac{z + \bar{z}}{2} \quad \text{and} \quad \Im(z) = \frac{z - \bar{z}}{2\mathrm{i}} \tag{5.2.100}$$

The "module" of z (or "norm") is the length from the center of the Gaussian plane (see further below a figure of the Gaussian plane) and is simply calculated using the Pythagorean theorem:

$$\boxed{|z|=\sqrt{x^2+y^2}=\sqrt{z\cdot\bar{z}}} \qquad (5.2.101)$$

and is always a positive number or equal to zero.

We will consider as obvious that it satisfies all the properties of a distance (see section of Topology page 2446 and Vector Calculus page 1794).

Remark

The notation $|z|$ for the module is not innocent since $|z|$ coincides with the absolute value of z when z is real.

The division between two complex number is calculated as (the denominator is obviously not zero):

$$\dfrac{z_1}{z_2}=\dfrac{x_1+\mathrm{i}y_1}{x_2+\mathrm{i}y_2}=\dfrac{x_1+\mathrm{i}y_1}{x_2+\mathrm{i}y_2}\cdot\dfrac{x_2-\mathrm{i}y_2}{x_2-\mathrm{i}y_2}=\dfrac{(x_1x_2+y_1y_2)-\mathrm{i}(x_1y_2-x_2y_1)}{x_2^2+y_2^2} \qquad (5.2.102)$$

The opposite of a complex number is calculated similarly:

$$\dfrac{1}{x+\mathrm{i}y}=\dfrac{x-\mathrm{i}y}{(x+\mathrm{i}y)(x-\mathrm{i}y)}=\dfrac{x-\mathrm{i}y}{x^2+y^2}=\dfrac{x}{x^2+y^2}-\mathrm{i}\dfrac{y}{x^2+y^2} \qquad (5.2.103)$$

We can therefore list 8 important properties of the module and the complex conjugate:

P1. We affirm that:

$$|z|=0\Leftrightarrow z=0 \qquad (5.2.104)$$

Proof 5.4.4. By definition of the module $|z|=\sqrt{x^2+y^2}$ so that the sum x^2+y^2 is zero, the necessary condition is that as $(x,y)\in\mathbb{R}$:

$$x=y=0 \qquad (5.2.105)$$

■ Q.E.D.

P2. We affirm that:

$$|z|=|-z|=|\bar{z}| \qquad (5.2.106)$$

Proof 5.4.5. This is immediate by:

$$|z|=\sqrt{x^2+y^2}=\sqrt{(-x)^2+(-y)^2}=|-z|=\sqrt{(x)^2+(-y)^2}=|\bar{z}| \qquad (5.2.107)$$

■ Q.E.D.

P3. We affirm that:

$$\begin{aligned}|\Re(z)|&\leqslant|z| \quad \text{with equality iif } z \text{ is real}\\|\Im(z)|&\leqslant|z| \quad \text{with equality iif } z \text{ is imaginary}\end{aligned} \qquad (5.2.108)$$

Proof 5.4.6. The two above inequalities can be written:

$$\begin{aligned}|x| &\leq \sqrt{x^2+y^2}\\ |y| &\leq \sqrt{x^2+y^2}\end{aligned}\tag{5.2.109}$$

thus equivalent respectively to:

$$\begin{aligned}x^2 &\leq \sqrt{x^2+y^2}\\ y^2 &\leq \sqrt{x^2+y^2}\end{aligned}\tag{5.2.110}$$

which are trivial. The rest of the proof is therefore trivial!

■ Q.E.D.

P4. We have:

$$\forall z_1, z_2 \in \mathbb{C}\times\mathbb{C} \qquad |z_1 z_2| = |z_1||z_2|\tag{5.2.111}$$

and if $z_2 \neq 0$:

$$\left|\frac{z_1}{z_2}\right| = \frac{|z_1|}{|z_2|}\tag{5.2.112}$$

Proof 5.4.7. First:

$$|z_1 z_2|^2 = (z_1 z_2)(\overline{z_1 z_2}) = (z_1 z_2)(\bar{z}_1\bar{z}_2) = (z_1\bar{z}_1)(z_2\bar{z}_2) = |z_1|^2|z_2|^2 \Rightarrow |z_1 z_2| = |z_1||z_2|\tag{5.2.113}$$

(we will prove a little further below that generally $\overline{z_1 z_2} = \bar{z}_1\bar{z}_2$) and for $z_2 \neq 0$:

$$\left|\frac{z_1}{z_2}\right|^2 = \frac{z_1}{z_2}\frac{\overline{z_1}}{z_2} = \frac{z_1}{z_2}\bar{z}_1\frac{\overline{1}}{z_2} = \frac{z_1}{z_2}\bar{z}_1\frac{1}{\bar{z}_2} = \frac{z_1\bar{z}_1}{z_2\bar{z}_2} = \frac{|z_1|^2}{|z_2|^2}\tag{5.2.114}$$

and taking root square this finish the proof.

■ Q.E.D.

P5. We affirm that:

$$|z|^2 = z\bar{z}\tag{5.2.115}$$

Proof 5.4.8. This is immediate:

$$|z|^2 = (\sqrt{x^2+y^2})^2 = (x+\mathrm{i}y)(x-\mathrm{i}y) = x^2 - \mathrm{i}xy + \mathrm{i}yx + y^2 = x^2+y^2 = \bar{z}z\tag{5.2.116}$$

■ Q.E.D.

P6. We affirm that:

$$\forall z, z' \in \mathbb{C} \quad \bar{\bar{z}} = z, \quad \overline{z+z'} = \bar{z}+\bar{z}', \quad \overline{zz'} = \bar{z}\bar{z}'\tag{5.2.117}$$

Proof 5.4.9. The first one is immediate:

$$\bar{\bar{z}}=\overline{\overline{x+\mathrm{i}y}}=\overline{x-\mathrm{i}y}=x+\mathrm{i}y=z \tag{5.2.118}$$

and:

$$\begin{aligned}\overline{z+z'}&=\overline{(x_1+\mathrm{i}y_1)+(x_2+\mathrm{i}y_2)}=\overline{(x_1+x_2)+\mathrm{i}(y_1+y_2)}=(x_1+x_2)-\mathrm{i}(y_1+y_2)\\&=(x_1-\mathrm{i}y_1)+(x_2-\mathrm{i}y_2)=\bar{z}+\bar{z}'\end{aligned} \tag{5.2.119}$$

and:

$$\begin{aligned}\overline{zz'}&=\overline{(x_1+\mathrm{i}y_1)(x_2+\mathrm{i}y_2)}=\overline{(x_1x_2-y_1y_2)+\mathrm{i}(x_1y_2+y_2x_2)}\\&=(x_1x_2-y_1y_2)+\mathrm{i}(x_1y_2+y_2x_2)=(x_1-\mathrm{i}y_1)(x_2-\mathrm{i}y_2)=\bar{z}\bar{z}'\end{aligned} \tag{5.2.120}$$

■ Q.E.D.

Remarks

R1. In mathematical terms, the first proof helps to show that complex conjugation is what is named an "involution" (in the sense that it is changing anything ...).

R2. Also in mathematical terms (it is only the vocabulary!), the second proof shows that the combination of the sum of two complex numbers is what we name a "group automorphism $(\mathbb{C},+)$" (see section Set Theory page 443).

R3. Again, for vocabulary ... the third proof show that the combination of the product of two complex numbers is what we name a "field automorphism $(\mathbb{C},+,\times)$" (see section Set Theory page 443).

P7. We affirm that for z different from zero:

$$\overline{\left(\frac{1}{z}\right)}=\frac{1}{\bar{z}}\qquad\overline{\left(\frac{z}{z'}\right)}=\frac{\bar{z}}{\bar{z}'} \tag{5.2.121}$$

Proof 5.4.10. We will restrict ourselves to the proof of the second relation that is a general case of the first (for $z=1$).

$$\begin{aligned}\overline{\left(\frac{z}{z'}\right)}&=\overline{\left(\frac{x_1+\mathrm{i}y_1}{x_2+\mathrm{i}y_2}\right)}=\overline{\left(\frac{x_1+\mathrm{i}y_1}{x_2+\mathrm{i}y_2}\right)\left(\frac{x_2-\mathrm{i}y_2}{x_2-\mathrm{i}y_2}\right)}=\overline{\frac{(x_1x_2+y_1y_2)+\mathrm{i}(y_1x_2-y_2x_1)}{x_2^2+y_2^2}}\\&=\frac{x_1x_2+y_1y_2}{x_2^2+y_2^2}-\mathrm{i}\frac{y_1x_2-y_2x_1}{x_2^2+y_2^2}=\frac{(x_1x_2+y_1y_2)+\mathrm{i}(y_2x_1-y_1x_2)}{x_2^2+y_2^2}\\&=\frac{(x_1-\mathrm{i}y_1)(x_2+\mathrm{i}y_2)}{x_2^2+y_2^2}=\frac{x_1-\mathrm{i}y_1}{x_2-\mathrm{i}y_2}\frac{x_2+\mathrm{i}y_2}{x_2+\mathrm{i}y_2}=\frac{\bar{z}}{\bar{z}'}\end{aligned} \tag{5.2.122}$$

■ Q.E.D.

P8. We have:

$$|z_1+z_2|\leqslant|z_1|+|z_2| \tag{5.2.123}$$

for any complex number z_1, z_2 (strictly speaking non-zero complex numbers, otherwise the concept of argument of the complex number that we will see further below is undetermined). Furthermore the equality holds if and only if z_1 and z_2 are collinear (the vectors are "on the same straight line") and of the same direction, in other words.... if it exist $\lambda \in \mathbb{R}$ such as $\lambda z_1 = z_2$.

Proof 5.4.11. Directly we have:

$$|z_1+z_2|^2 = |z_1|^2 + 2\Re(z_1\bar{z}_2) + |z_2|^2 \leqslant |z_1|^2 + 2|z_1\bar{z}_2| + |z_2|^2 = (|z_1|+|z_2|)^2 \tag{5.2.124}$$

This inequality may not be obvious to everyone, therefore let us develop it a bit and let us assume it true:

$$\begin{aligned}
&|z_1+z_2|^2 \overset{?}{\leqslant} (|z_1|+|z_2|)^2\\
&\sqrt{(x_1+x_2)^2+(y_1+y_2)^2}^2 \overset{?}{\leqslant} \left(\sqrt{x_1^2+y_1^2}+\sqrt{x_2^2+y_2^2}\right)^2\\
&(x_1+x_2)^2+(y_1+y_2)^2 \overset{?}{\leqslant} (x_1^2+y_1^2)+2\sqrt{x_1^2+y_1^2}\sqrt{x_2^2+y_2^2}+(x_2^2+y_2^2)\\
&x_1^2+2x_1x_2+x_2^2+y_1^2+2y_1y_2+y_2^2 \overset{?}{\leqslant} (x_1^2+y_1^2)+2\sqrt{x_1^2+y_1^2}\sqrt{x_2^2+y_2^2}+(x_2^2+y_2^2)
\end{aligned} \tag{5.2.125}$$

After simplification:

$$\begin{aligned}
&x_1x_2+y_1y_2 \overset{?}{\leqslant} \sqrt{x_1^2+y_1^2}\sqrt{x_2^2+y_2^2}\\
&(x_1x_2+y_1y_2)^2 \overset{?}{\leqslant} (x_1^2+y_1^2)(x_2^2+y_2^2)\\
&x_1^2x_2^2+2x_1x_2y_1y_2+y_1^2y_2^2 \overset{?}{\leqslant} x_1^2x_2^2+x_1^2y_2^2+y_1^2x_2^2+y_1^2y_2^2
\end{aligned} \tag{5.2.126}$$

and again after simplification:

$$\begin{aligned}
&2x_1x_2y_1y_2 \overset{?}{\leqslant} x_1^2y_2^2+y_1^2x_2^2\\
&0 \overset{?}{\leqslant} x_1^2y_2^2-2x_1x_2y_1y_2+y_1^2x_2^2\\
&0 \overset{?}{\leqslant} (x_1y_2-y_1x_2)^2
\end{aligned} \tag{5.2.127}$$

So as the square brackets is necessarily positive or zero it follows:

$$0 \leq (x_1y_2-y_1x_2)^2 \tag{5.2.128}$$

This last relation thus shows that inequality is true.

■ Q.E.D.

Remark

In fact there is a more general form of this inequality named "Minkowski inequality", proved in the section of Vector Calculus page 1828 (complex numbers can indeed be written in the form of vectors as we will see later).

5.2.2.7.1 Geometric Interpretation of Complex Numbers

We can also represent any complex number $a + ib$ or $a - ib$ in a plane defined by two axes (two dimensions) of infinite length and orthogonal between them. The vertical axis represents the imaginary part of a complex number and the horizontal axis the real part (see figure below).

So there is correspondence between the set of complex numbers $\mathbb{C}$ and the set of vectors of the Gaussian plane $\mathbb{R}^2$.

We sometimes name this type of representation "Gauss plane" or "Gauss map" and we name "affix" the point with Cartesian coordinates (a, b) that is identified with the complex number $a + ib$ itself.

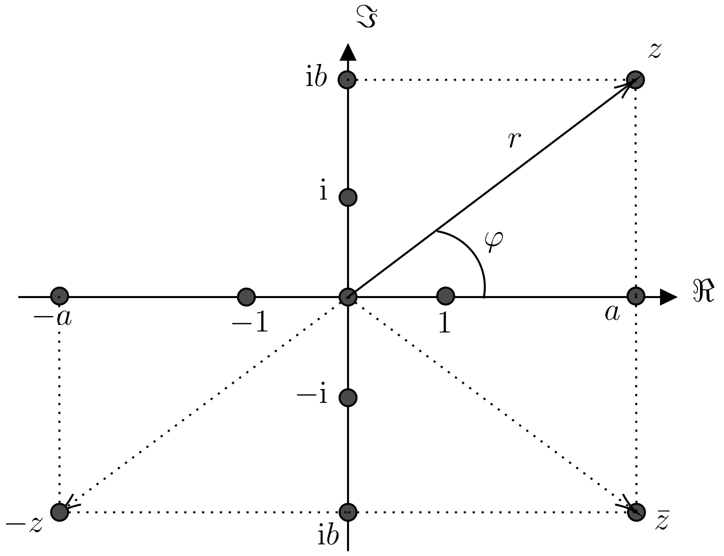

Figure 5.18: Complex Gauss plane

and then we write:

$$\text{Aff}(\vec{r}) = a + \mathrm{i}b \tag{5.2.129}$$

We see on this diagram that a complex number has thus a vector interpretation (see section Vector Calculus page 1797) given by:

$$z = a\begin{pmatrix}1\\0\end{pmatrix} + b\begin{pmatrix}0\\1\end{pmatrix} = a + \mathrm{i}b \tag{5.2.130}$$

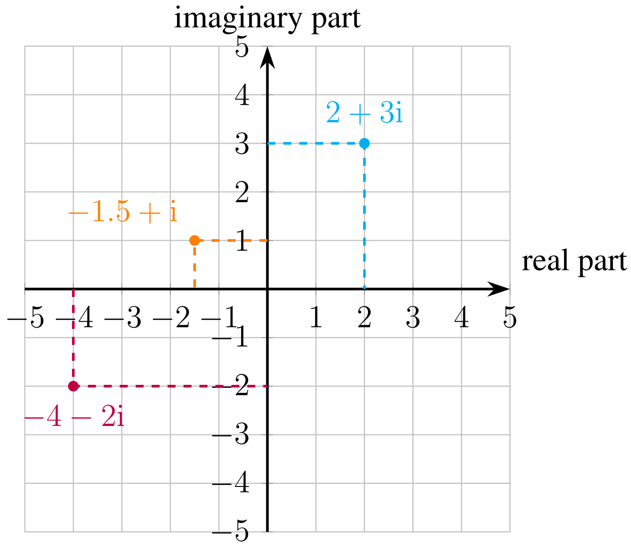
where the canonical basis is defined such as:

$$\left\{1 = \begin{pmatrix}1\\0\end{pmatrix}, \mathrm{i} = \begin{pmatrix}0\\1\end{pmatrix}\right\} \tag{5.2.131}$$

with:

$$r=|z|=\sqrt{a^2+b^2} \tag{5.2.132}$$

Thus, $\begin{pmatrix}1\\0\end{pmatrix}$ is the unitary basis vector of the carried by the horizontal axis $\mathbb{R}$ and $\begin{pmatrix}0\\1\end{pmatrix}$ is the unitary basis vector carried by the vertical imaginary axis $\mathbb{R}_\mathrm{i}$ and r is the module (the norm) that is positive or zero.



This has to be compared with the canonical vectors basis of $\mathbb{R}^2$ (see section Vector Calculus page 1810):

$$\vec{v}=x\vec{e}_1+y\vec{e}_2=x\begin{pmatrix}1\\0\end{pmatrix}+y\begin{pmatrix}0\\1\end{pmatrix}=\begin{pmatrix}x\\y\end{pmatrix} \tag{5.2.133}$$

with:

$$\|\vec{v}\|=\sqrt{x^2+y^2} \tag{5.2.134}$$

so that we can identify the complex plane with the Euclidean plane.

Thanks to the geometric interpretation of the Gaussian plane, the equality below is immediate for example and avoids making some developments:

$$\left|\frac{a+b\mathrm{i}}{b+a}\right|=1 \tag{5.2.135}$$

In addition, the definitions of the cosine and sine (see section Trigonometry page 2508) give us:

$$a=r\cos(\varphi) \qquad b=r\sin(\varphi) \tag{5.2.136}$$

Finally:

$$\boxed{\begin{aligned}&r=\sqrt{a^2+b^2}\\&\varphi^{-1}=\cos^{-1}\left(\frac{a}{r}\right)=\sin^{-1}\left(\frac{b}{r}\right)=\tan^{-1}\left(\frac{b}{a}\right)\end{aligned}} \tag{5.2.137}$$

Therefore:

$$z=a+\mathrm{i}b=r\cos(\varphi)+\mathrm{i}r\sin(\varphi)=r(\cos(\varphi)+\mathrm{i}\sin(\varphi))=r\mathrm{cis}(\varphi) \tag{5.2.138}$$

complex number which is always equal to itself modulo 2π by the properties of trigonometric functions:

$$\boxed{z=r(\cos(\varphi)+\mathrm{i}\sin(\varphi))=r(\cos(\varphi+2k\pi)+\mathrm{i}\sin(\varphi+2k\pi))} \tag{5.2.139}$$

with $k\in\mathbb{N}$ and where φ is named the "argument of z" and is traditionally denoted by:

$$\arg(z) \tag{5.2.140}$$

The properties of the cosine and sine (see section Trigonometry page 2514) lead us directly to write for the argument:

$$\arg(\bar{z})=-\arg(z)\quad\text{and}\quad\arg(-z)=\arg(z+\pi) \tag{5.2.141}$$

We also prove among other things with the Taylor series (see section Sequences and Series page 1704) that:

$$\cos(\varphi)=1-\frac{\varphi^2}{2!}+\frac{\varphi^4}{4!}-\ldots+(-1)^k\frac{\varphi^{2k}}{(2k)!}+\ldots \tag{5.2.142}$$

and:

$$\sin(\varphi)=\varphi-\frac{\varphi^3}{3!}+\frac{\varphi^5}{5!}-\ldots+(-1)^k\frac{\varphi^{2k+1}}{(2k+1)!}+\ldots \tag{5.2.143}$$

which sum is similar to:

$$e^{\varphi}=1+\varphi+\frac{\varphi^2}{2!}+\frac{\varphi^3}{3!}+\ldots+\frac{\varphi^k}{k!}+\ldots \tag{5.2.144}$$

but instead perfectly identical to the Taylor expansion of $e^{\mathrm{i}x}$:

$$e^{\mathrm{i}\varphi}=1+\mathrm{i}\varphi-\frac{\varphi^2}{2!}-\mathrm{i}\frac{\varphi^3}{3!}+\ldots+\mathrm{i}^k\frac{\varphi^k}{k!}+\ldots=\cos(\varphi)+\mathrm{i}\sin(\varphi) \tag{5.2.145}$$

So finally, we can write:

$$\boxed{z=r(\cos(\varphi)+\mathrm{i}\sin(\varphi))=re^{\mathrm{i}\varphi}} \tag{5.2.146}$$

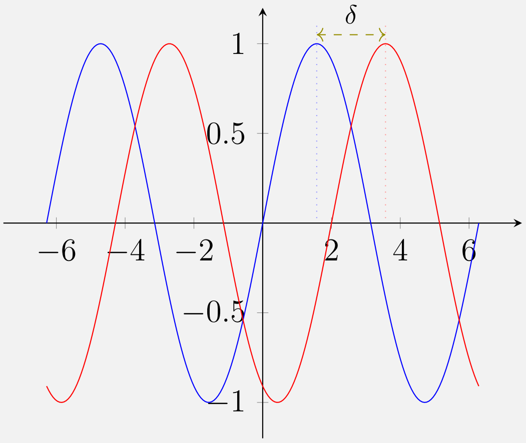
relation named "Euler's formula".

Remark

Notice that:

$$z=r(\cos(\varphi+\delta)+\mathrm{i}\sin(\varphi+\delta))=re^{\mathrm{i}(\varphi+\delta)}=re^{\mathrm{i}\varphi}e^{\mathrm{i}\delta} \tag{5.2.147}$$

where δ is named a "phase-shift" and $e^{\mathrm{i}\delta}$ is named a "phase-shift factor":



Using the properties of trigonometric functions:

$$\begin{aligned}\cos(\varphi)+\mathrm{i}\sin(\varphi)&=e^{\mathrm{i}\varphi}\\ \cos(\varphi)-\mathrm{i}\sin(\varphi)&=e^{-\mathrm{i}\varphi}\end{aligned}\tag{5.2.148}$$

Depending on we sum or subtract this gives us the "Euler formulas" or "de Moivre and Euler formulas":

$$\boxed{\begin{aligned}\cos(\varphi)&=\frac{e^{\mathrm{i}\varphi}+e^{-\mathrm{i}\varphi}}{2}\\ \sin(\varphi)&=\frac{e^{\mathrm{i}\varphi}-e^{-\mathrm{i}\varphi}}{2\mathrm{i}}\end{aligned}}\tag{5.2.149}$$

Notice that the angle can be a purely a complex number! This is to say that in all generality trigonometric functions can be considered as functions that go from $\mathbb{C}$ to $\mathbb{C}$.

Remark

Notice that these relations are very useful to linearise expressions such as $\cos^k(\theta)$ or $\sin^k(\theta)$. Indeed:

$$\begin{aligned}\sin^6(\theta)&=\left(\frac{e^{\mathrm{i}\theta}-e^{-\mathrm{i}\theta}}{2\mathrm{i}}\right)^6\\ &=-\frac{1}{64}\left(e^{\mathrm{i}6\theta}-6e^{\mathrm{i}5\theta}e^{-\mathrm{i}\theta}+15e^{\mathrm{i}4\theta}e^{-\mathrm{i}2\theta}-20e^{\mathrm{i}3\theta}e^{-\mathrm{i}3\theta}+15e^{\mathrm{i}2\theta}e^{-\mathrm{i}4\theta}-6e^{\mathrm{i}\theta}e^{-\mathrm{i}5\theta}+e^{-\mathrm{i}6\theta}\right)\\ &=-\frac{1}{64}\left(e^{\mathrm{i}6\theta}-6e^{\mathrm{i}4\theta}+15e^{\mathrm{i}2\theta}-20+15e^{-\mathrm{i}2\theta}-6e^{-\mathrm{i}4\theta}+e^{-\mathrm{i}6\theta}\right)\\ &=-\frac{1}{64}\left(e^{\mathrm{i}6\theta}+e^{-\mathrm{i}6\theta}-6\left(e^{\mathrm{i}4\theta+e^{-\mathrm{i}4\theta}}\right)+15\left(e^{\mathrm{i}2\theta}+e^{-\mathrm{i}2\theta}\right)\right)\\ &=-\frac{1}{32}\left(\cos(6\theta)-6\cos(4\theta)+15\cos(2\theta)-10\right)\end{aligned}\tag{5.2.150}$$

A well known special case for the formulas above is the case where $\varphi = \pi$ and $r = 1$. Then we have:

$$e^{\mathrm{i}\pi} = \cos(\pi) + \mathrm{i}\sin(\pi) = -1 \tag{5.2.151}$$

after rearranging we get the famous geek relation:

$$e^{\mathrm{i}\pi} + 1 = 0 \tag{5.2.152}$$

Another famous geek case is when we take still $r = 1$ but with $\varphi = \pi/2$ and we raise to the power of i. Then we get:

$$e^{\mathrm{i}\pi/2} = \cos(\pi/2) + \mathrm{i}\sin(\pi/2) = \mathrm{i} \tag{5.2.153}$$

and if we raise that to the power of i:

$$\mathrm{i}^{\mathrm{i}} = \left(e^{\mathrm{i}\pi/2}\right)^{\mathrm{i}} = e^{\mathrm{i}^2\pi/2} = e^{-\pi/2} \cong 0.20788 \tag{5.2.154}$$

Some people consider then as a curious fact that i raised to the i-th power is actually a real number.

Thanks to the exponential form of a complex number, very commonly used in many fields of physics and engineering, we can easily draw relations such that starting from (remember that cis is an old notation that stands for the $\cos(\varphi) + \mathrm{i}\sin(\varphi)$ being in the parenthesis):

$$\begin{aligned} z &= r(\cos(\varphi) + \mathrm{i}\sin(\varphi)) = r\text{cis}(\varphi) = re^{\mathrm{i}\varphi} \\ z_1 &= r_1(\cos(\varphi_1) + \mathrm{i}\sin(\varphi_1)) = r_1\text{cis}(\varphi_1) = r_1e^{\mathrm{i}\varphi_1} \\ z_2 &= r_2(\cos(\varphi_2) + \mathrm{i}\sin(\varphi_2)) = r_1\text{cis}(\varphi_2) = r_2e^{\mathrm{i}\varphi_2} \end{aligned} \tag{5.2.155}$$

and assuming known the basic trigonometric identities (see section Trigonometry page 2519) we have the following relations for the multiplication of two complex numbers:

$$z_1z_2 = r_1r_2\left[\cos(\varphi_1 + \varphi_2) + \mathrm{i}\sin(\varphi_1 + \varphi_2)\right] = r_1e^{\mathrm{i}\varphi_1}r_2e^{\mathrm{i}\varphi_2} = r_1r_2\text{cis}(\varphi_1 + \varphi_2) = r_1r_2e^{\mathrm{i}(\varphi_1+\varphi_2)} \tag{5.2.156}$$

therefore:

$$\arg(z_1z_2) = \arg(z_1) + \arg(z_2) \tag{5.2.157}$$

and therefore if n is a positive integer:

$$\arg(z^n) = n\arg(z) \tag{5.2.158}$$

For the module (norm) of the multiplication:

$$|z_1z_2| = |r_1e^{\mathrm{i}\varphi_1}r_2e^{\mathrm{i}\varphi_2}| = |r_1r_2e^{\mathrm{i}(\varphi_1+\varphi_2)}| = r_1r_2 = |r_1||r_2| \tag{5.2.159}$$

Therefore:

$$|z^m| = |z|^m \tag{5.2.160}$$

For the division of two complex numbers:

$$\frac{z_1}{z_2}=\frac{r_1}{r_2}\left[\cos(\varphi_1-\varphi_2)+\mathrm{i}\sin(\varphi_1-\varphi_2)\right]=\frac{r_1}{r_2}\mathrm{cis}(\varphi_1-\varphi_2)=\frac{r_1}{r_2}\frac{e^{\mathrm{i}\varphi_1}}{e^{\mathrm{i}\varphi_2}}=\frac{r_1}{r_2}e^{\mathrm{i}(\varphi_1-\varphi_2)} \quad (5.2.161)$$

The module of their division then comes immediately:

$$\left|\frac{z_1}{z_2}\right|=\frac{|z_1|}{|z_2|} \quad (5.2.162)$$

therefore we have for the argument:

$$\arg\left(\frac{z_1}{z_2}\right)=\arg\left(\frac{r_1e^{\mathrm{i}\phi_1}}{r_2e^{\mathrm{i}\phi_2}}\right)=\arg\left(\frac{r_1}{r_2}e^{\mathrm{i}(\varphi_1-\varphi_2)}\right)=\varphi_1-\varphi_2=\arg(z_1)-\arg(z_2) \quad (5.2.163)$$

and it comes immediately:

$$\arg(z^{-1})=\arg\left(\left(re^{\mathrm{i}\phi}\right)^{-1}\right)=\arg\left(\frac{1}{r}e^{\mathrm{i}\varphi}\right)=-\varphi=-\arg(z) \quad (5.2.164)$$

For the power of a complex number (or root):

$$z^m=r^me^{\mathrm{i}m\varphi}=r^m\left[\cos(m\varphi)+\mathrm{i}\sin(\varphi)\right]=r^m\mathrm{cis}(m\varphi) \quad (5.2.165)$$

which gives us immediately as already proved previously:

$$|z^m|=|z|^m \quad (5.2.166)$$

and for the argument:

$$\arg(z^m)=\arg\left(\left(re^{\mathrm{i}\varphi}\right)^m\right)=\arg\left(r^me^{m\mathrm{i}\varphi}\right)=m\varphi=m\arg(z) \quad (5.2.167)$$

In case we have a unit module (norm equal to 1) as $z=\cos(\varphi)+\mathrm{i}\sin(\varphi)$ we then have the relation:

$$(\cos(\varphi)+\mathrm{i}\sin(\varphi))^m=\left(e^{\mathrm{i}\varphi}\right)^m=e^{\mathrm{i}m\varphi}=\cos(m\varphi)+\mathrm{i}\sin(m\varphi) \quad (5.2.168)$$

named "de Moivre formula".

For the natural logarithm of a complex number, we trivially have the following relation which is discussed in the section of Functional Analysis (page 2284):

$$\ln(z)=\ln\left(re^{\mathrm{i}\varphi}\right)=\ln(r)+\mathrm{i}\varphi \quad (5.2.169)$$

where $\ln(z)$ is often in the complex case written $\mathrm{Log}(z)$ with an uppercase "L".

All previous relations could of course be obtained with the trigonometric form of complex numbers but then require some additional lines of mathematical developments.

Remark

Notice that the previous developments allow us to calculate things (...) like $\cos(\bar{z})$. Indeed, let $z = x + \mathrm{i}y$ and consider:

$$\overline{e^{\mathrm{i}z}} = \overline{e^{\mathrm{i}(x+\mathrm{i}y)}} = \overline{e^{-y}e^{\mathrm{i}x}} = e^{-y}e^{-\mathrm{i}x} = e^{-\mathrm{i}(x-\mathrm{i}y)} = e^{-\mathrm{i}\bar{z}} \tag{5.2.170}$$

Similarly, we have:

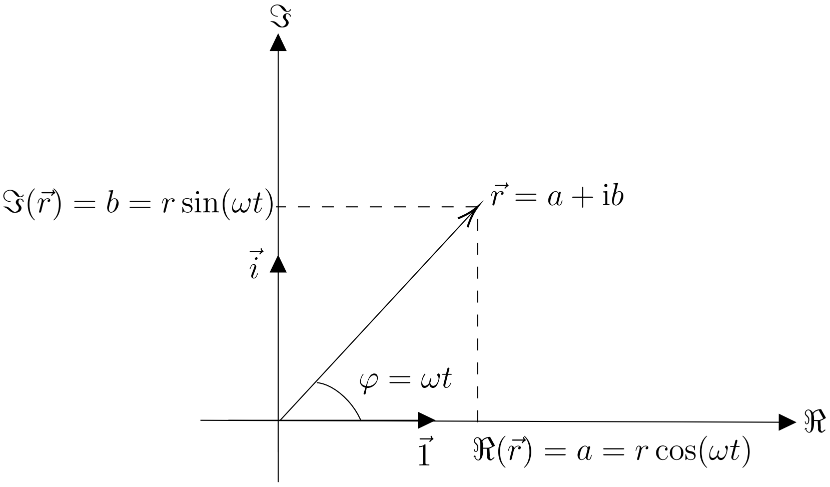
$$\overline{e^{-\mathrm{i}z}} = e^{\mathrm{i}\bar{z}} \tag{5.2.171}$$

Now consider:

$$\overline{\cos(z)} = \overline{\frac{1}{2}(e^{\mathrm{i}z} + e^{-\mathrm{i}z})} = \frac{1}{2}(e^{-\mathrm{i}z} + e^{\mathrm{i}\bar{z}}) = \cos(\bar{z}) \tag{5.2.172}$$

5.2.2.7.1.1 Fresnel Vectors (phasors)

A sinusoidal variation $f(t) = r\sin(\omega t)$ can be represented as the projection (see section Trigonometry page 2503) on the vertical y-axis (imaginary axis the set $\mathbb{C}$) of a rotating vector $\vec{r}$ at angular velocity ω around the origin in the plane xOy:



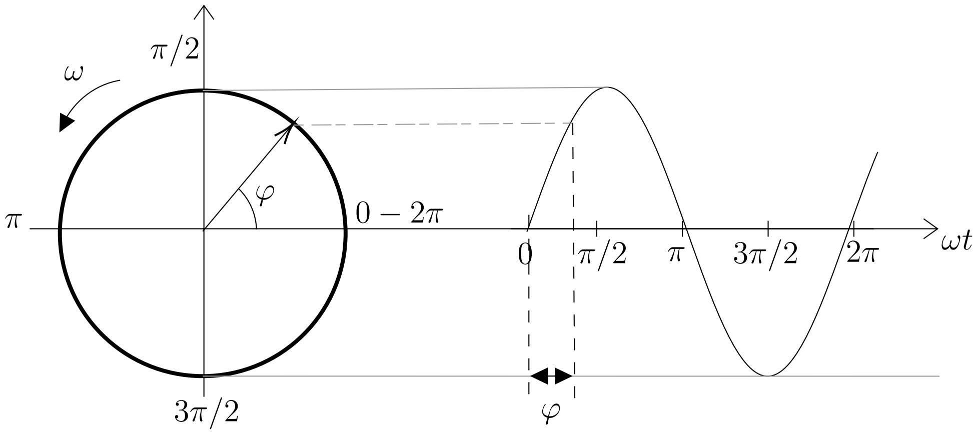
$\Im$
$\Im(\vec{r}) = b = r\sin(\omega t)$
$\vec{r} = a + \mathrm{i}b$
$\vec{i}$
$\varphi = \omega t$
$\vec{1}$
$\Re(\vec{r}) = a = r\cos(\omega t)$
$\Re$

Figure 5.19: **Fresnel representation**

Such a rotating vector is named "Fresnel vector" and can be well interpreted as the imaginary part of a complex number given by:

$$\vec{r} = \Re(\vec{r}) + \mathrm{i}\Im(\vec{r}) = r(\cos(\omega t) + \mathrm{i}\sin(\omega t)) = re^{\mathrm{i}\omega t} = re^{\mathrm{i}\phi} \tag{5.2.173}$$

That is to say:



$\pi/2$

We will see the phasor again explicitly in our study of wave mechanics and geometrical optics (as part of diffraction) in the sections with the corresponding names page 3475 and page 4314.

5.2.2.7.2 Transformation in the plane

It is customary to represent real numbers as points on a graduated line. The algebraic operations have their geometric interpretation on it: the addition is a translation, a multiplication a centered scaling.

In particular we can talk about the "square root of a transformation." A translation of amplitude T may be obtained as the iteration of a translation of amplitude $T/2$. Similarly, a scaling of amplitude S can be achieved as iterated scaling of faction $\sqrt{S}$. In particular an homothety (scaling) of a factor 9 can be composed of two homotheties (scaling) of respectively 3 (or -3).

Then we can say that the square root takes on a geometric sense. But what about the square root of negative numbers? In particular of the square root of -1???

A scaling of factor -1 can be seen as a symmetry with respect to the origin. But if we see this transformation in a continuous manner. Therefore a -1 scaling factor also be seen as rotation of π rotation around the origin.

So, the problem of negative square root is simplified. Indeed, it is not difficult to break down a rotation of π radians into two transformations: we can repeat either a rotation of $\pi/2$ or of $-\pi/2$. The image of 1 is the square root of -1 and i is situated on a perpendicular to the origin at a distance 1 either up or down.

Having successfully positioned the number i it not difficult anymore to put other complex numbers in the Gauss plane. We can therefore associate to $2\mathrm{i}$ the product of the scaling of a factor 2 (see section Euclidean Geometry page 2643) by the rotation of center O with angle of $\pi/2$, that is to say a similitude centered at the origin. This is what we will endeavour to prove now.

Given:

$$z_1 = x_1 + \mathrm{i}y_1 = ae^{\mathrm{i}\alpha}, z_2 = x_2 + \mathrm{i}y_2 = be^{\mathrm{i}\beta} \qquad (5.2.174)$$

We have the following geometric transformations properties for complex numbers (see the section Trigonometry at page 2519 for the properties of sine and cosine) that we can happily combine at our discretion:

P1. The multiplication of z_1 by a real number λ in the Gauss plane corresponds trivially to a homothety of center O (the intersection of real and imaginary axis for recall...) and of ratio λ.

Indeed:

$$\lambda z_1 = (\underline{\lambda a})e^{\mathrm{i}\alpha} \qquad (5.2.175)$$

P2. Multiplication of z_1 by a complex number of unit module corresponds a rotation of center O and of angle corresponding to the argument of z_1. Indeed:

$$z_0 z_1 = e^{\mathrm{i}\omega}ae^{\mathrm{i}\alpha} = ae^{\mathrm{i}(\alpha+\omega)} \qquad (5.2.176)$$

Remark

Then we see immediately, for example, that multiplying a complex number by i (that is to say a complex number with $\sin(\omega)=1,\cos(\omega)=0$) corresponds a rotation of $\pi/2$.

Theorem 5.5. It is interesting to notice that in vector form the rotation of center O of z_1 by z_0 can be written using the following matrix:

$$\begin{bmatrix} x_0 & -y_0 \\ y_0 & x_0 \end{bmatrix} \tag{5.2.177}$$

Proof 5.5.1. We have just seen before that z_0z_1 is a rotation of center O of and angle ω. We just need to write it first in the old style:

$$z_0z_1=(x_0+\mathrm{i}y_0)(x_1+\mathrm{i}y_1)=(x_0x_1-y_0y_1)+\mathrm{i}(x_0y_1+y_0x_1) \tag{5.2.178}$$

giving in vector form:

$$z_0z_1=\begin{pmatrix} x_0x_1-y_0y_1 \\ 0 \end{pmatrix}+\mathrm{i}\begin{pmatrix} 0 \\ x_0y_1+y_0x_1 \end{pmatrix} \tag{5.2.179}$$

thus the linear equivalent application is:

$$\begin{bmatrix} x_0 & -y_0 \\ y_0 & x_0 \end{bmatrix}\begin{pmatrix} x_1 \\ y_1 \end{pmatrix}=\begin{pmatrix} x_0x_1-y_0x_1 \\ x_0y_1+y_0y_1 \end{pmatrix} \tag{5.2.180}$$

or as well (we fall back on the rotation matrix in the plane that we will see in the section of Euclidean Geometry page 2648 which is a remarkable result!) using:

$$z=r(\cos(\varphi)+\mathrm{i}\sin(\varphi))=r(\cos(\varphi+k2\pi)+\mathrm{i}\sin(\varphi+k2\pi)) \tag{5.2.181}$$

and in the particular and arbitrary case where r is unitary (in order to have a pure rotation!):

$$z=\cos(\varphi+k2\pi)+\mathrm{i}\sin(\varphi+k2\pi)=x_0+\mathrm{i}y_0 \tag{5.2.182}$$

we have immediately (we took again the same notations for the angle as the one we have in the chapter Geometry):

$$\begin{bmatrix} x_0 & -y_0 \\ y_0 & x_0 \end{bmatrix}\begin{pmatrix} x_1 \\ y_1 \end{pmatrix}=\begin{bmatrix} \cos\omega & -\sin\omega \\ \sin\omega & \cos\omega \end{bmatrix}\begin{pmatrix} x_1 \\ y_1 \end{pmatrix}=\begin{pmatrix} x_0x_1-y_0y_1 \\ x_0y_1+y_0x_1 \end{pmatrix}=\begin{pmatrix} \cos(\omega)x_1-\sin(\omega)y_1 \\ \cos(\omega)y_1+\sin(\omega)x_1 \end{pmatrix} \tag{5.2.183}$$

Notice that the 2D rotation matrix can also be written as:

$$\begin{bmatrix} \cos(\omega) & -\sin(\omega) \\ \sin(\omega) & \cos(\omega) \end{bmatrix}=\cos(\omega)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}+\sin(\omega)\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}=\cos(\omega)I+\sin(\omega)J \tag{5.2.184}$$

as well:

$$\begin{bmatrix} x_0 & -y_0 \\ y_0 & x_0 \end{bmatrix}=x_0\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}+y_0\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}=x_0\cdot I+y_0\cdot J \tag{5.2.185}$$

■ Q.E.D.

Thus we see that the rotation matrices are not only applications but also are complex numbers (well it was obvious from the start but we had to show it in an aesthetic and simple way).

So, we have for usage to put that:

$$\boxed{1=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\quad\text{and}\quad \mathrm{i}=\begin{bmatrix}0 & -1\\ 1 & 0\end{bmatrix}}\tag{5.2.186}$$

or with another common notation in linear algebra:

$$\mathbb{1}=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\quad\text{and}\quad \mathrm{i}=\begin{bmatrix}0 & -1\\ 1 & 0\end{bmatrix}\tag{5.2.187}$$

The field of complex numbers is isomorphic to the field of real square matrices of dimension 2 of the type:

$$\begin{bmatrix}x_0 & -y_0\\ y_0 & x_0\end{bmatrix}\tag{5.2.188}$$

It is a result that we use many times in various sections of this book for specific studies in algebra, geometry and relativistic quantum physics.

P3. The multiplication of two complex corresponds to a homothety added to a rotation. In other words, a "direct similarity".

Proof 5.5.2.

$$z_1z_2=ae^{\mathrm{i}\alpha}be^{\mathrm{i}\beta}=(\underline{ab})e^{\mathrm{i}\underline{(\alpha+\beta)}}\tag{5.2.189}$$

so this is indeed a similarity of ratio b and angle β.

At the opposite, the following operation:

$$z_1\overline{z_2}=ae^{\mathrm{i}\alpha}be^{-\mathrm{i}\beta}=(\overline{ab})e^{\mathrm{i}\underline{(\alpha-\beta)}}\tag{5.2.190}$$

will be named a "retrograde linear similarity".

Otherwise, it returns trivially an already known following relation:

$$\arg(z_1z_2)=\arg(z_1)+\arg(z_2)\tag{5.2.191}$$

Remarks

R1. As the sum of two complex numbers z_1+z_2 can not have a special simplified mathematical notation in any form whatsoever, then we say that the resulting quantity is equivalent to an "amplitude translation".

R2. The combination of a direct linear similarity (multiplication of two complex numbers) and an amplitude translation (sum by a third complex number) is what we name a "direct linear similarity".

■ Q.E.D.

P4. The conjugate of a complex number is geometrically symmetrical with respect to the real axis such that:

$$\bar{z}_1 = x_1 - \mathrm{i}y_1 = r(\cos(\alpha) - \mathrm{i}\sin(\alpha)) = r(\cos(-\alpha) - \mathrm{i}\sin(-\alpha)) = re^{-\mathrm{i}\alpha} \tag{5.2.192}$$

without forgetting that (basis of trigonometry):

$$\cos(\varphi) = \cos(\varphi + k2\pi) \qquad \sin(\varphi) = \sin(\varphi + k2\pi) \tag{5.2.193}$$

This gives us a known result:

$$\arg(\bar{z}_1) = -\arg(z_1) \tag{5.2.194}$$

From which we get the following property:

$$r(\cos(\varphi + \pi) + \mathrm{i}\sin(\varphi + \pi)) = r\left(-\cos(\varphi) - \mathrm{i}\sin(\varphi)\right) = -r\left(\cos(\varphi) + \mathrm{i}\sin(\varphi)\right) = -z_1 \tag{5.2.195}$$

Hence:

$$\arg(z_1) + \pi = -\arg(-z_1) \tag{5.2.196}$$

P5. The negation of the conjugate of a complex number is geometrically its symmetrical with respect to the imaginary axis such that:

$$-\bar{z}_1 = -x_1 + \mathrm{i}y_1 = r(-\cos(\alpha) + \mathrm{i}\sin(\alpha)) = r(\cos(\pi \pm \alpha) + \mathrm{i}\sin(\alpha)) \tag{5.2.197}$$

Remarks

R1. The combination of the properties P4, P5 is named a "retrograde similarity".

R2. The geometric operation that consist to take the inverse of the conjugate of a complex number (that is to say $\bar{z}^{-1}$) is named a "pole inversion".

P6. The rotation of coordinate center c and angle φ is given and denoted by:

$$\mathcal{R}(z_1) = c + e^{\mathrm{i}\varphi}(z_1 - c) \tag{5.2.198}$$

Some explanations could be useful for some readers:

The complex c gives a point in the Gaussian plane, which will be the center of rotation. The difference $z_1 - c$ gives the chosen radius r. The multiplication by $e^{\mathrm{i}\varphi}$ is the counter-clockwise rotation of the radius from the origin of the Gaussian plane. Finally, the addition by c is the necessary translation to take back the rotated radius r at its original place before the rotation (center c). Which gives schematically:

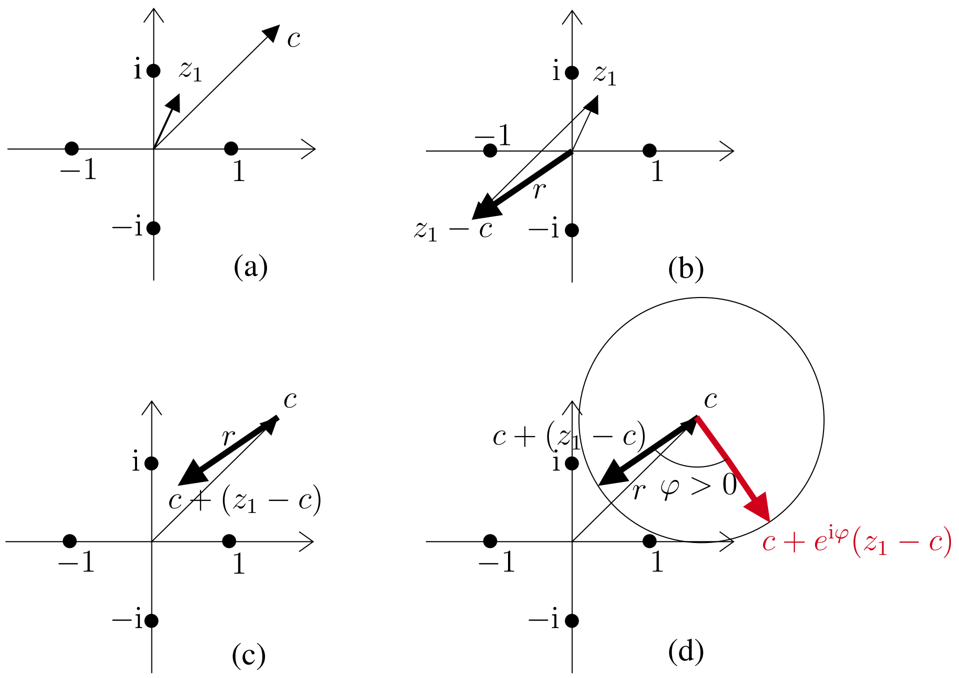

Figure 5.22: **Representation of the complex rotation**

P7. On the same idea, we get and denote an homothety of center c and ratio λ by:

$$\mathcal{H}(z_1) = c + \lambda(z_1 - c) \tag{5.2.199}$$

Some explanations could be useful for some readers:

The difference $z_1 - c$ always gives the radius r and c a central point in the Gauss plane. The expression $\lambda(z_1 - c)$ gives the homothety of the radius from the origin of the Gaussian plane, and finally by adding c gives the necessary translation for the homothety to be seen as being made from center c.

5.2.2.8 Quaternion Numbers

Also named "hypercomplex" quaternions numbers were invented in 11843 (holocene calendar) by William Rowan Hamilton to generalize complex numbers.

Definition (#5.2.39): A "quaternion" is an element $(a, b, c, d) \in \mathbb{R}^4$ and for which we denote by $\mathbb{H}$ the set that contains it and what we name the "set of quaternions".

A quaternion can also be represented in a row or column such as:

$$(a, b, c, d) = \begin{pmatrix} a \\ b \\ c \\ d \end{pmatrix} \tag{5.2.200}$$

We define the sum of two quaternions (a, b, c, d) and (a', b', c', d') by:

$$(a, b, c, d) + (a', b', c', d') = (a + a', b + b', c + c', d + d') \tag{5.2.201}$$

Remark

It is the natural addition in $\mathbb{R}^4$ seen as a $\mathbb{R}$-vector space (see section Set Theory page 1805).

The associativity is verified by applying the corresponding properties of the operations on $\mathbb{R}$.

We also define the multiplication:

$$(a, b, c, d) \cdot (a', b', c', d') \tag{5.2.202}$$

of two quaternions (a, b, c, d) and (a', b', c', d') by the expression:

$$(a, b, c, d) \cdot (a', b', c', d') = \begin{pmatrix} aa' - bb' - cc' - dd' \\ (ab' + ba') + (cd' - dc') \\ (ac' + ca') - (bd' - db') \\ (da' + ad') + (bc' - cb') \end{pmatrix} \tag{5.2.203}$$

It may be hard to accept but we will be a little further below that there is a family resemblance with the complex numbers.

We can notice that the law of multiplication is not commutative. Indeed, taking the definition of the multiplication above, we have:

$$\begin{aligned} (0, 1, 0, 0) \cdot (0, 0, 1, 0) &= (0, 0, 0, 1) \\ (0, 0, 1, 0) \cdot (0, 1, 0, 0) &= (0, 0, 0, -1) \end{aligned} \tag{5.2.204}$$

But we can also notice that:

$$(0, 1, 0, 0) \cdot (0, 0, 1, 0) = -1(0, 0, 1, 0) \cdot (0, 1, 0, 0) \tag{5.2.205}$$

Remark

It is the natural multiplication in $\mathbb{R}^4$ seen as a $\mathbb{R}$-vector space (see section Set Theory page 1805).

The law of multiplication is distributive with the addition law but it is an excellent example where we must still be careful to prove the left and right distributivity, since the product is not commutative!

The multiplication has for neutral element:

$$(1, 0, 0, 0) \tag{5.2.206}$$

Indeed:

$$(1, 0, 0, 0) \cdot (a, b, c, d) = (a, b, c, d) \cdot (1, 0, 0, 0) = (a, b, d, c) \tag{5.2.207}$$

Any element:

$$(a, b, c, d) \in \mathbb{H}^* = \mathbb{H} - \{(0, 0, 0, 0)\} \tag{5.2.208}$$

is invertible.

Indeed, if (a,b,c,d) is a non-null quaternion, we then have necessarily:

$$a^2+b^2+c^2+d^2\neq 0 \tag{5.2.209}$$

otherwise the four numbers a,b,c,d are of square null, so all zero. Given then the quaternion (a_1,b_1,c_1,d_1) defined by:

$$\begin{aligned} a_1&=\frac{a}{a^2+b^2+c^2+d^2}\\ b_1&=\frac{-b}{a^2+b^2+c^2+d^2}\\ c_1&=\frac{-c}{a^2+b^2+c^2+d^2}\\ d_1&=\frac{-d}{a^2+b^2+c^2+d^2} \end{aligned} \tag{5.2.210}$$

then by applying mechanically the definition of the multiplication of quaternions, we check that:

$$(a,b,c,d)\cdot(a_1,b_1,c_1,d_1)=(a_1,b_1,c_1,d_1)\cdot(a,b,c,d)=(1,0,0,0) \tag{5.2.211}$$

this latter quaternion is therefore the inverse for the multiplication!

Let us prove (for general knowledge) that the field of complex numbers $(\mathbb{C},+,\times)$ is a subfield of $(\mathbb{H},+,\times)$.

Remark

We could also have put this proof in the section of Set Theory because we will make use of a lot of concepts that are have seen there but it seemed to us a little more relevant to put instead the proof here. We expect the reader to tolerate this choice.

Given $\mathbb{H}'$ a set of quaternions of the form $(a,b,0,0)$. If $\mathbb{H}'$ is not empty, and if $(a,b,0,0)$, $(a',b',0.0)$ are elements $\mathbb{H}'$ then $(\mathbb{H}',+\times)$ is a field. Indeed:

P1. For subtraction (and therefore the addition):

$$(a,b,0,0)-(a',b',0,0)=(a-a',b-b',0,0)\in\mathbb{H}' \tag{5.2.212}$$

P2. The multiplication:

$$(a,b,0,0)\cdot(a',b',0,0)=(aa'-bb',ab'+ba',0,0)\in\mathbb{H}' \tag{5.2.213}$$

P3. The neutral element:

$$(1,0,0,0)\in\mathbb{H}' \tag{5.2.214}$$

P4. And finally the inverse:

$$\left(\frac{a}{a^2+b^2},-\frac{b}{a^2+b^2},0,0\right)\in\mathbb{H}' \tag{5.2.215}$$

of $(a,b,0,0)$ is still in $\mathbb{H}'$.

Therefore $(\mathbb{H}', +, \times)$ is a subfield of $\mathbb{H}$. Given then the application:

$$\begin{gathered} f : a + \mathrm{i}b \to (a, b, 0, 0) \\ \mathbb{C} \to \mathbb{H} \end{gathered} \tag{5.2.216}$$

f is bijective, and we easily check that for any complex z_1, z_2, we have:

$$\begin{gathered} f(z_1 + z_2) = f(z_1) + f(z_2) \\ f(z_1 z_2) = f(z_1) f(z_2) \end{gathered} \tag{5.2.217}$$

Therefore f is an isomorphism of $(\mathbb{C}, +, \times)$ on $(\mathbb{H}', +, \times)$.

This isomorphism has for interest (caused) to identify $\mathbb{C}$ to $\mathbb{H}'$ and to write $\mathbb{C} \subset \mathbb{H}$, the laws of addition and subtraction on $\mathbb{H}$ extending the already known operations of $\mathbb{C}$.

Thus, by convention, we will write any element of $(a, b, 0, 0)$ of $\mathbb{H}'$ in the complex form $a + \mathrm{i}b$. Particularly 0 is the element $(0, 0, 0, 0)$, 1 is the element $(1, 0, 0, 0)$ and i and the element $(0, 1, 0, 0)$.

We denote by analogy and by extension j the element $(0, 0, 1, 0)$ and k the element $(0, 0, 0, 1)$. The family $\{1, \mathrm{i}, \mathrm{j}, \mathrm{k}\}$ form a basis of all quaternions seen as a vector space on $\mathbb{R}$, and we will write:

$$\underbrace{a}_{\text{scalar part}} + \underbrace{b\mathrm{i} + c\mathrm{j} + d\mathrm{k}}_{\text{vector part}} \tag{5.2.218}$$

the quaternion (a, b, c, d).

The notation of quaternions as defined above is perfectly suited to the multiplication operation. For the product of two quaternions we get by developing the expression:

$$(a + b\mathrm{i} + c\mathrm{j} + d\mathrm{k}) \cdot (a' + b'\mathrm{i} + c'\mathrm{j} + d'\mathrm{k}) \tag{5.2.219}$$

16 terms that we have to identify to the original definition of multiplication of quaternions to get the following relations:

$$\begin{aligned} &\mathrm{i} \cdot \mathrm{j} = \mathrm{k} = -\mathrm{j} \cdot \mathrm{i} \\ &\mathrm{j} \cdot \mathrm{k} = \mathrm{i} = -\mathrm{k} \cdot \mathrm{j} \\ &\mathrm{k} \cdot \mathrm{i} = \mathrm{j} = -\mathrm{i} \cdot \mathrm{k} \\ &\mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = -1 \end{aligned} \tag{5.2.220}$$

Which can be summarized in a table:

$\cdot$	1	i	j	k
1	1	i	j	k
i	i	-1	k	$-\mathrm{j}$
j	j	$-\mathrm{k}$	-1	i
j	j	j	$-\mathrm{i}$	-1

(5.2.221)

Or in a 3D representation of what happens in the corresponding 4D sphere (red, green and blue for i, j and k respectively):

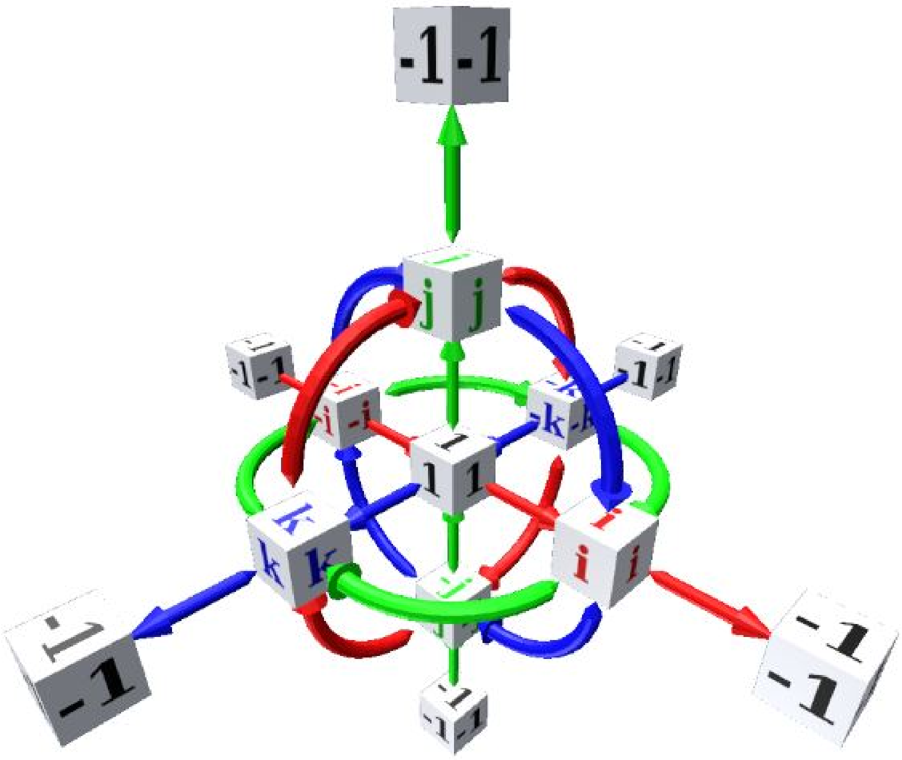

Figure 5.23: **Starting situation for quaternion rotations**

We can see that the expression of the multiplication of two quaternions looks partly much like a vector product (denoted × in this book) and dot product (denoted ∘ in this book):

$$\begin{pmatrix} aa'-bb'-cc'-dd' \\ (ab'+ba')+(cd'-dc') \\ (ac'+ca')-(bd'-db') \\ (da'+ad')+(bc'-cb') \end{pmatrix} \tag{5.2.222}$$

If this is not evident (which would be quite understandable), let us make a concrete example:

✍**Example:**

Given two quaternions without real part:

$$p=x\mathrm{i}+y\mathrm{j}+z\mathrm{k} \qquad q=x'\mathrm{i}+y'\mathrm{j}+z'\mathrm{k} \tag{5.2.223}$$

and $\vec{u},\vec{v}$ the vectors of $\mathbb{R}^3$ of respective components (x,y,z) and (x',y',z'). Then the product:

$$pq=(0,\vec{u})(0,\vec{v}) \tag{5.2.224}$$

is equal to:

$$p\cdot q=(-xx'-yy'-zz',yz'-zy',-xz'+zx',xy'-yx')=(-\vec{u}\circ\vec{v},\vec{u}\times\vec{v}) \tag{5.2.225}$$

We can also for curiosity interest us to the general case ... Given for this two quaternions:

$$p=(a,\vec{u}) \qquad q=(b,\vec{v}) \tag{5.2.226}$$

Then we have:

$$\begin{aligned} p\cdot q &= (a+(0,\vec{u}))\cdot(b+(0,\vec{v}))\\ &= ab+(0,a\vec{v})+(0,b\vec{u})+(-\vec{u}\circ\vec{v},\vec{u}\times\vec{v})\\ &= (ab-\vec{u}\circ\vec{v},a\vec{v}+b\vec{u}+\vec{u}\times\vec{v}) \end{aligned} \tag{5.2.227}$$

Definition (#5.2.40): The center of the non-commutative field $(\mathbb{H},+,\times)$ is the set of elements of $\mathbb{H}$ commuting for the law of multiplication with all the elements of $\mathbb{H}$.

Theorem 5.6. The center of $(\mathbb{H},+,\times)$ is the set of real numbers!

Proof 5.6.1. Give $\mathbb{H}_1$ is the center of $(\mathbb{H},+,\times)$, and (x,y,z,t) a quaternion. We must have the following conditions that are met:

Given $(x,y,z,t)\in\mathbb{H}_1$ then for any $(a,b,c,d)\in\mathbb{H}$ we seek:

$$(x,y,z,t)\cdot(a,b,c,d)=(a,b,c,d)\cdot(x,y,z,t) \tag{5.2.228}$$

which give by developing:

$$\begin{aligned} xa-yb-zc-td&=ax-by-cz-dt\\ xb+ya+zd-tc&=ay+bx+ct-dz\\ xc+za-yd+tb&=az+cx-bt+dy\\ ta+xd+yc-zb&=dx+at+bz-cy \end{aligned} \tag{5.2.229}$$

after simplification (the first line of the previous system is equal to zero on both sides of equality):

$$\begin{aligned} ct-dz&=0\\ bt-dy&=0\\ bz-cy&=0 \end{aligned} \tag{5.2.230}$$

the resolution of this system gives us:

$$y=z=t=0 \tag{5.2.231}$$

So that the quaternion (x,y,z,t) is the center of $\mathbb{H}$ it must be real (not imaginary parts)!

■ Q.E.D.

Just as for complex numbers, we can define a conjugate of quaternions:

Definition (#5.2.41): The conjugate of a quaternion $Z=(a,b,c,d)$ is the quaternion $\bar{Z}=(a,-b,-c,-d)$.

Just as for the complex number, we notice that:

1. First clearly that if $Z=\bar{Z}$ then it means that $Z\in\mathbb{R}$

2. That $Z+\bar{Z}\in\mathbb{R}$
3. That by developing the product $Z\bar{Z}$ we have:

$$\begin{aligned}Z\bar{Z}&=(a,b,c,d)\cdot(a,-b,-c,-d)\\&=(a^2+b^2+c^2+d^2,-ab+ba-cd+dc,-ac+ca+bd-db,da-ad-bc+cb)\\&=(a^2+b^2+c^2+d^2,0,0,0)=a^2+b^2+c^2+d^2\in\mathbb{R}\end{aligned} \tag{5.2.232}$$

that we will adopt, by analogy with complex numbers, as a definition of the norm (or module) of quaternions such as:

$$|Z|=\sqrt{Z\cdot\bar{Z}} \tag{5.2.233}$$

Therefore we also have immediately (relation which will be useful later):

$$|ZZ'|=\sqrt{(ZZ')(\overline{ZZ'}} \tag{5.2.234}$$

As for complex numbers (see below), it is easy to show that the conjugation is an automorphism of the group $(\mathbb{H},+)$.

Indeed, given $Z=(a,b,c,d)$ and $Z'=(a',b',c',d')$ then:

$$\begin{aligned}\overline{Z+Z'}&=(a+a',-b-b',-c-c',-d-d')\\&=(a,-b,-c,-d)+(a',-b',-c',-d')\\&=\bar{Z}+\bar{Z}'\end{aligned} \tag{5.2.235}$$

It is also easy to prove that it is involutive. Indeed:

$$\bar{\bar{Z}}=(a,-(-b),-(-c),-(-d))=(a,b,c,d)=Z \tag{5.2.236}$$

But the conjugation is not a multiplicative automorphism of the field $(\mathbb{H},+,\times)$. Indeed, if we consider the multiplication of Z, Z' and take the conjugate:

$$ZZ'=\begin{pmatrix}aa'-bb'-cc'-dd'\\(ab'+ba')+(cd'-dc')\\(ac'+ca')-(bd'-db')\\(da'+ad')+(bc'-cb')\end{pmatrix}\qquad\overline{ZZ'}=\begin{pmatrix}aa'-bb'-cc'-dd'\\-(ab'+ba')-(cd'-dc')\\-(ac'+ca')+(bd'-db')\\-(da'+ad')-(bc'-cb')\end{pmatrix} \tag{5.2.237}$$

we see immediately (at least for the second row) that we have:

$$ZZ'\neq\overline{ZZ'} \tag{5.2.238}$$

Let us now back to our norm (or module) .... For this, let us calculate the square of the norm $|ZZ'|$:

$$|ZZ'|^2=(ZZ')\cdot(\overline{ZZ'}) \tag{5.2.239}$$

We know (by definition) that:

$$ZZ'=\begin{pmatrix}aa'-bb'-cc'-dd'\\(ab'+ba')+(cd'-dc')\\(ac'+ca')-(bd'-db')\\(da'+ad')+(bc'-cb')\end{pmatrix} \tag{5.2.240}$$

Let us denote this product in such a way that:

$$Z\cdot Z'=(\alpha,\beta,\gamma,\lambda)=Z\text{"}\tag{5.2.241}$$

Then we have:

$$Z\text{"}\overline{Z\text{"}}=\alpha^2+\beta^2+\gamma^2+\lambda^2\tag{5.2.242}$$

substituting it comes:

$$\begin{aligned}(ZZ')\cdot\overline{(ZZ')}=&(aa'-bb'-cc'-dd')^2+(ab'+ba'+cd'-dc')^2\\&+(ac'+ca'-bd'+db')^2+(da'+ad'+bc'-cb')^2\end{aligned}\tag{5.2.243}$$

after an elementary algebraic development (frankly boring) we find:

$$(ZZ')\cdot\overline{(ZZ')}=(a'^2+b'^2+c'^2+d'^2)(a^2+b^2+c^2+d^2)=|Z'|^2|Z|^2\tag{5.2.244}$$

Therefore:

$$(ZZ')\cdot\overline{(ZZ')}=|Z|^2|Z'|^2=|ZZ'|^2\tag{5.2.245}$$

Remark

The norm is therefore a homomorphism (see section Set Theory page 441) of $(\mathbb{H},\times)$ in $(\mathbb{R},\times)$. Subsequently, we will denote by $\mathbb{G}$ all the quaternions of unit norm.

5.2.2.8.1 Matrix Interpretation of Quaternions

Given q and p two quaternions and given the application:

$$p\rightarrow qp\tag{5.2.246}$$

The (left) multiplication can be made with a linear application (see section Linear Algebra page 1934) on $\mathbb{H}$.

If q is written:

$$a+b\mathrm{i}+c\mathrm{j}+d\mathrm{k}\tag{5.2.247}$$

this application has for matrix in the basis $(1,\mathrm{i},\mathrm{j},\mathrm{k})$:

$$\begin{bmatrix}a&-b&-c&-d\\b&a&-d&c\\c&d&a&-b\\d&-c&b&a\end{bmatrix}\tag{5.2.248}$$

What we check well:

$$ZZ'=\begin{bmatrix}a&-b&-c&-d\\b&a&-d&c\\c&d&a&-b\\d&-c&b&a\end{bmatrix}\begin{pmatrix}a'\\b'\\c'\\d'\end{pmatrix}=\begin{pmatrix}aa'-bb'-cc'-dd'\\(ab'+ba')+(cd'-dc')\\(ac'+ca')-(bd'-db')\\(da'+ad')+(bc'-cb')\end{pmatrix}\tag{5.2.249}$$

In fact, we can then define the quaternions as the set of matrices with the visible structure above if we wanted to. This will then reduce them to a sub vector space of $M_4(\mathbb{R})$.

Especially, the matrix of 1 (the real part of the quaternion q) is then nothing other than the identity matrix:

$$M_1=\begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{bmatrix}=\mathbb{1} \tag{5.2.250}$$

as well:

$$M_i=\begin{bmatrix}0&-1&0&0\\1&0&0&0\\0&0&0&-1\\0&0&1&0\end{bmatrix},\quad M_j=\begin{bmatrix}0&0&-1&0\\0&0&0&1\\1&0&0&0\\0&-1&0&0\end{bmatrix},\quad M_k=\begin{bmatrix}0&0&0&-1\\0&0&-1&0\\0&1&0&0\\1&0&0&0\end{bmatrix} \tag{5.2.251}$$

5.2.2.8.2 Rotations with Quaternions

We will see now that conjugation by an element of the group $\mathbb{G}$ of the quaternions of unit norm can be interpreted as a pure rotation in space!

Definition (#5.2.42): The "conjugation" by a non-null quaternion q of unit norm is the application S_q defined on $\mathbb{H}$ by:

$$\boxed{S_q : p \rightarrow q\cdot p\cdot q^{-1}=q\cdot p\cdot\bar{q}} \tag{5.2.252}$$

and we affirm that this application is a rotation.

Remarks

R1. As q is of unit norm 1, we have obviously $|q|=q\bar{q}=1$ therefore $q^{-1}=\bar{q}$. This quaternion can be seen as the proper value (of unit norm) to the application (matrix) p on the vector $\bar{q}$ (we are in a similar situation as the orthogonal rotation matrices seen in the section of Linear Algebra page 1954).

R2. S_q is a linear application (so if it is rotation, the rotation can be decomposed into several rotations). Indeed, let consider two quaternions p_1,p_2 and two real number λ_1,λ_2, then we have:

$$S_q(\lambda_1p_1+\lambda_2p_2)=q(\lambda_1p_1+\lambda_2p_2)\bar{q}=\lambda_1qp_1\bar{q}+\lambda_2qp_2\bar{q}=\lambda_1S_q(p_1)+\lambda_2S_q(p_2) \tag{5.2.253}$$

Let us now check that the application is indeed a pure rotation. As we saw in our study of Linear Algebra and in particular of orthogonal matrices (see section Linear Algebra page 1954), a first obvious condition is that the application conserves the norm.

Let us check this:

$$|S_q(p)|=|qp\bar{q}|=|q||p||\bar{q}|=|p| \tag{5.2.254}$$

Moreover, we can check that a rotation of a purely complex quaternion (such that then we restrict ourselves to $\mathbb{R}^3$) and the same summed reverse rotation is zero (the vector sum up to its opposite cancel):

$$S_q(p)+\overline{S_q(p)}=qp\bar{q}+\overline{qp\bar{q}}=qp\bar{q}+\overline{q(p\bar{q})} \tag{5.2.255}$$

we trivially check that if we have two quaternions q,p then $\overline{p\cdot q}=\bar{q}\bar{p}$ since then:

$$\begin{aligned}S_q(p)+\overline{S_q(p)}&=qp\bar{q}+\overline{q(p\bar{q})}=qp\bar{q}+\overline{(p\bar{q})}\bar{q}\\&=q\cdot p\cdot\bar{q}+\bar{\bar{q}}\cdot\bar{p}\cdot\bar{q}=q\cdot p\cdot\bar{q}+q\cdot\bar{p}\cdot\bar{q}\\&=S_q(p+\bar{p})\end{aligned} \tag{5.2.256}$$

for this operation to be zero, we immediately see that we need to restrict ourselves to the purely complex quaternions p. Since then:

$$S_q(p+\bar{p})=S_q(0)=0 \tag{5.2.257}$$

We conclude then that p must be purely complex so the for the application S_q is a rotation and that $S_q(p)$ is a pure quaternion. In other words, this application is stable (in other words: a pure quaternion by this application remains a pure quaternion).

The application S_q restricted to all purely complex quaternions is thus a vectorial isometry, that is to say a symmetry or a rotation.

We have also seen during our study of the rotation matrices in the section of Linear Algebra page 2001 and Euclidean Geometry page 2648 that such matrices should have a determinant equal to $+1$ so that we have a rotation. Let's see if this is the case of S_q:

For this, we explicitly calculate in function of:

$$q=a+b\mathrm{i}+c\mathrm{j}+d\mathrm{k} \tag{5.2.258}$$

the matrix (in the canonical basis $(\mathrm{i},\mathrm{j},\mathrm{k})$) of S_q and we calculate its determinant. Thus we obtain the coefficients of the columns of this application by remembering that:

$$\begin{aligned}\mathrm{ij}&=\mathrm{k}=-\mathrm{ji}\\\mathrm{jk}&=\mathrm{i}=-\mathrm{kj}\\\mathrm{ki}&=\mathrm{j}=-\mathrm{ik}\\\mathrm{i}^2&=\mathrm{j}^2=\mathrm{k}^2=-1\end{aligned} \tag{5.2.259}$$

and then by calculating:

$$\begin{aligned}S_q(\mathrm{i})&=(a+b\mathrm{i}+c\mathrm{j}+d\mathrm{k})\mathrm{i}(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\&=(a\mathrm{i}+b(\mathrm{i}^2)+c(\mathrm{ji})+d(\mathrm{ki}))(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\&=(a\mathrm{i}-b-c\mathrm{k}+d\mathrm{j})(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\&=(a2\mathrm{i}+ab-ac\mathrm{k}+ad\mathrm{j})-(ba-b^2\mathrm{i}-bc\mathrm{j}-bd\mathrm{k})\\&-(ca\mathrm{k}-cb\mathrm{j}+c^2\mathrm{i}+cd)+(da\mathrm{j}+db\mathrm{k}+cd-d^2\mathrm{i})\\&=(a^2+b^2-c^2-d^2)\mathrm{i}+(\cancel{ab}-ac\mathrm{k}+ad\mathrm{j})-(\cancel{ba}-bc\mathrm{j}-bd\mathrm{k})\\&-(ca\mathrm{k}-cb\mathrm{j}+\cancel{cd})+(da\mathrm{j}+db\mathrm{k}+\cancel{cd})\\&=(a^2+b^2-c^2-d^2)\mathrm{i}+2(ad+bc)\mathrm{j}+2(bd-ac)\mathrm{k}\end{aligned} \tag{5.2.260}$$

$$\begin{aligned}
S_q(\mathrm{j}) &= (a+b\mathrm{i}+c\mathrm{j}+d\mathrm{k})\mathrm{j}(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\
&= (a\mathrm{j}+b(\mathrm{ij})+c(\mathrm{j}^2)+d(\mathrm{kj}))(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\
&= (a\mathrm{j}+b\mathrm{k}-c-d\mathrm{i})(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\
&= (a^2\mathrm{j}+ab\mathrm{k}+ac-ad\mathrm{i})+(ba\mathrm{k}-b^2\mathrm{j}+bc\mathrm{i}+bd)\\
&-(ca-cb\mathrm{i}-c^2\mathrm{j}-cd\mathrm{k})-(da\mathrm{i}+db-dc\mathrm{k}+d^2\mathrm{j})\\
&= (a^2-b^2+c^2-d^2)\mathrm{j}+(ab\mathrm{k}+\cancel{ac}-ad\mathrm{i})+(ba\mathrm{k}+bc\mathrm{i}+\cancel{bd})\\
&-(\cancel{ca}-cb\mathrm{i}-cd\mathrm{k})-(da\mathrm{i}+\cancel{db}-dc\mathrm{k})\\
&= 2(bc-ad)\mathrm{i}+(a^2-b^2+c^2-d^2)\mathrm{j}+2(ab+cd)\mathrm{k}
\end{aligned} \tag{5.2.261}$$

$$\begin{aligned}
S_q(\mathrm{k}) &= (a+b\mathrm{i}+c\mathrm{j}+d\mathrm{k})\mathrm{k}(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\
&= (a\mathrm{k}+b(\mathrm{ik})+c(\mathrm{jk})+d)(\mathrm{k}^2))(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\
&= (a\mathrm{k}-b\mathrm{j}+c\mathrm{i}-d)(a-b\mathrm{i}-c\mathrm{j}-d\mathrm{k})\\
&= (a^2\mathrm{k}-ab\mathrm{j}+ac\mathrm{i}+ad)-(ab\mathrm{j}+b^2\mathrm{k}+bc-bd\mathrm{i})\\
&+(ca\mathrm{i}+cb-c^2\mathrm{k}+cd\mathrm{j})-(da-db\mathrm{i}-dc\mathrm{j}-d^2\mathrm{k})\\
&= (a^2-b^2-c^2+d^2)\mathrm{k}+(-ab\mathrm{j}+ac\mathrm{i}+\cancel{ad})-(ab\mathrm{j}+\cancel{bc}-bd\mathrm{i})\\
&+(ca\mathrm{i}+\cancel{cb}+cd\mathrm{j})-(\cancel{da}-db\mathrm{i}-dc\mathrm{j})\\
&= 2(ac+bd)\mathrm{i}+2(cd-ab)\mathrm{j}+(a^2-b^2-c^2+d^2)\mathrm{k}
\end{aligned} \tag{5.2.262}$$

We must then calculate the determinant of the following matrix (pfff ...):

$$\begin{bmatrix}
a^2+b^2-c^2-d^2 & 2(ad+bc) & 2(bd-ac)\\
2(bc-ad) & a^2-b^2+c^2-d^2 & 2(ab+cd)\\
2(ac+bd) & 2(cd-ab) & (a^2-b^2-c^2+d^2)
\end{bmatrix} \tag{5.2.263}$$

remembering that (which also simplifies the expression of the terms of the diagonal as we can see in some books):

$$a^2+b^2+c^2+d^2=1 \tag{5.2.264}$$

we find that the determinant is indeed equal to 1. Otherwise, we can check this with Maple™ 4.00b:

```
>with(linalg):
>A:=linalg[matrix](3,3,[a^2+b^2-c^2-d^2,2*(a*d+b*c),
2*(b*d-a*c),2*(b*c-a*d),a^2-b^2+c^2-d^2,2*(a*b+c*d),
2*(a*c+b*d),2*(c*d-a*b),a^2-b^2-c^2+d^2]);
>factor(det(A));
```

Let us now show that this rotation is a half axis turn (the example that may seem particular is in fact general!):

First, if:

$$q=x\mathrm{i}+y\mathrm{j}+z\mathrm{k} \tag{5.2.265}$$

we have:

$$S_q(q)=qq\bar{q}=q \qquad (5.2.266)$$

which means that the axis of rotation (x,y,z) is fixed by the application S_q itself!

On the other hand, we have seen that if q is a purely complex quaternion of norm 1 then:

$$q^{-1}=\bar{q} \qquad \text{and} \qquad \bar{q}=-q \qquad (5.2.267)$$

Which gives us the relation:

$$q^2=q\cdot(-\bar{q})=q\cdot(-(q^{-1}))=-1 \qquad (5.2.268)$$

This result leads us to calculate the rotation of a rotation:

$$S_q(S_q(p))=q(qp\bar{q})\bar{q}=q^2p\bar{q}^2=S_{q^2}(p)=(-1)p(-q)^2=-pq^2=(-1)p(-1)=p \qquad (5.2.269)$$

Conclusion: Since the rotation of a rotation is a full turn, then S_q is necessarily a half-turn:

$$S_q(p)=-p \qquad (5.2.270)$$

relatively (!) to the axis (x,y,z).

At this stage, we can say that any rotation of the space can be represented by S_q (the conjugation by a quaternion q of norm 1). Indeed, the half turns generates the group of rotations, that is to say that any rotation can be expressed as the product of a finite number of half-turns, and therefore by conjugation of a product of quaternions unitary norm (product which is itself a quaternion of unitary norm...).

We will still give an explicit form connecting a rotation and the quaternion that represents it, just as we did for complex numbers.

Theorem 5.7. Given $\vec{u}(x,y,z)$ a unit vector and $\theta\in[0,2\pi]$ angle. Then we affirm that the rotation of axis $\vec{u}$ and angle θ corresponds to the application S_q, where q is the quaternion:

$$\boxed{q=\cos\left(\frac{\theta}{2}\right)+x\sin\left(\frac{\theta}{2}\right)+y\sin\left(\frac{\theta}{2}\right)\mathrm{j}+z\sin\left(\frac{\theta}{2}\right)\mathrm{k}=\left(\cos\left(\frac{\theta}{2}\right),\sin\left(\frac{\theta}{2}\right)\vec{u}\right)\begin{pmatrix}\cos\left(\frac{\theta}{2}\right)\\ x\sin\left(\frac{\theta}{2}\right)\\ y\sin\left(\frac{\theta}{2}\right)\\ z\sin\left(\frac{\theta}{2}\right)\end{pmatrix}} \qquad (5.2.271)$$

For this assertion is verified, we know we need that:

- The norm of q is equal to 1
- The determinant of the application S_q is equal to 1
- The application S_q conserves the norm
- The application S_q returns all collinear vector to the axis of rotation on the axis of rotation itself.

Proof 5.7.1. Ok let us check every point:

1. The norm of the quaternion previously proposed is indeed equal to 1:

$$\begin{aligned}|q|&=\cos^2\left(\frac{\theta}{2}\right)+x^2\sin^2\left(\frac{\theta}{2}\right)+y^2\sin^2\left(\frac{\theta}{2}\right)+z^2\sin^2\left(\frac{\theta}{2}\right)\\&=\cos^2\left(\frac{\theta}{2}\right)+\sin^2\left(\frac{\theta}{2}\right)(x^2+y^2+z^2)\\&=\cos^2\left(\frac{\theta}{2}\right)+\sin^2\left(\frac{\theta}{2}\right)=1\end{aligned}\tag{5.2.272}$$

   and as $\vec{u}(x,y,z)$ is of unit norm, we have:

$$x^2+y^2+z^2=1\tag{5.2.273}$$

   Therefore:

$$|q|=\cos^2\left(\frac{\theta}{2}\right)+\sin^2\left(\frac{\theta}{2}\right)(x^2+y^2+z^2)=\cos^2\left(\frac{\theta}{2}\right)+\sin^2\left(\frac{\theta}{2}\right)=1\tag{5.2.274}$$

2. The fact that q is a quaternion of unit norm immediately leads to the fact that the determinant of the application S_q is also equal to 1. We have already proved it above in the general case of any quaternion of norm 1 (necessary and sufficient condition).

3. It is the same for the conservation of the norm. We have already proved earlier above that this was the case anyway when the quaternion q of norm 1 (necessary and sufficient condition).

4. Let us now prove that all collinear vector to the axis of rotation is projected onto the axis of rotation itself. Let us denote by q' the purely imaginary unitary quaternion $xi+yj+zk$. Then we have:

$$q=\cos\left(\frac{\theta}{2}\right)+\sin\left(\frac{\theta}{2}\right)q'\tag{5.2.275}$$

   Then:

$$S_q(q')=qq'\bar{q}\tag{5.2.276}$$

   but as q' is the restriction of q to the pure elements that constitute it, this is equivalent as to write:

$$S_q(q')=S_q(q)=qq\bar{q}=q\tag{5.2.277}$$

   Let us now show why we choose the writing $\theta/2$. If $\vec{v}=(x_1,y_1,z_1)$ denotes a unit vector orthogonal to $\vec{u}$ (therefore perpendicular to the axis of rotation), and p the quaternion $x\mathrm{i}+y\mathrm{j}+z\mathrm{k}$ then we have:

$$\begin{aligned}S_q(p)&=\left(\cos\left(\frac{\theta}{2}\right)+\sin\left(\frac{\theta}{2}\right)q'\right)p\left(\cos\left(\frac{\theta}{2}\right)-\sin\left(\frac{\theta}{2}\right)q'\right)\\&=\cos^2\left(\frac{\theta}{2}\right)p+\cos\left(\frac{\theta}{2}\right)\sin\left(\frac{\theta}{2}\right)(q'p-pq')-\sin^2\left(\frac{\theta}{2}\right)q'pq'\end{aligned}\tag{5.2.278}$$

We have shown during the definition of multiplication of two quaternions that:

$$pq' = -q'p \tag{5.2.279}$$

therefore we get:

$$\begin{aligned} S_q(p) &= \cos^2\left(\frac{\theta}{2}\right)p + 2\cos\left(\frac{\theta}{2}\right)\sin\left(\frac{\theta}{2}\right)q'p - \sin^2\left(\frac{\theta}{2}\right)q'pq' \\ &= \cos^2\left(\frac{\theta}{2}\right)p + 2\cos\left(\frac{\theta}{2}\right)\sin\left(\frac{\theta}{2}\right)q'p + \sin^2\left(\frac{\theta}{2}\right)q'p(-q') \\ &= \cos^2\left(\frac{\theta}{2}\right)p + 2\cos\left(\frac{\theta}{2}\right)\sin\left(\frac{\theta}{2}\right)q'p + \sin^2\left(\frac{\theta}{2}\right)q'p\bar{q}' \end{aligned} \tag{5.2.280}$$

We have also prove earlier above that:

$$S_q(p) = -p = qp\bar{q} \tag{5.2.281}$$

Therefore:

$$q'p\bar{q}' = S_{q'}(p) = -p \tag{5.2.282}$$

(the half turn of axis (x, y, z)). So:

$$\begin{aligned} S_{q'}(p') &= \cos^2\left(\frac{\theta}{2}\right)p + 2\cos\left(\frac{\theta}{2}\right)\sin\left(\frac{\theta}{2}\right)q'p - \sin^2\left(\frac{\theta}{2}\right)p \\ &= \left(\cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)\right)p + 2\cos\left(\frac{\theta}{2}\right)\sin\left(\frac{\theta}{2}\right)q'p \\ &= \cos(\theta)p + \sin(\theta)q'p \end{aligned} \tag{5.2.283}$$

Remark

We are beginning to see here already the usefulness of having chose from the beginning $\theta/2$ for the angle!

■ Q.E.D.

We know that p is the pure quaternion likened to a unit vector $\vec{v}$ orthogonal to the axis of rotation $\vec{u}$ itself equated with the purely imaginary part of q'. We notice then immediately that the imaginary part of the product (defined!) of the quaternion $q'p$ is equal to the cross product $\vec{u} \times \vec{v} = \vec{w}$. This vector product therefore generates a vector perpendicular to $\vec{u}, \vec{v}$.

The pair $(\vec{v}, \vec{w})$ thus form a plane perpendicular to the axis of rotation $\vec{u}$ (that's as for the simple complex numbers $\mathbb{C}$ in which we have the Gaussian plane and perpendicular to it the axis of rotation!).

Then finally:

$$S_q(p) = \cos(\theta)p + \sin(\theta)q'p = \cos(\theta)\vec{v} + \sin(\theta)\vec{w} \tag{5.2.284}$$

We fall back with on rotation based on a plane (but therefore be in space!) identical to that shown earlier above with the standard complex numbers $\mathbb{C}$ in the Gaussian plane. For more details the reader can refer the section of Spinor Calculus page 2145.

So we know how to do any kind of rotation in space in a single mathematical operation and with a bonus: with the free choice of the axis!

We can now better understand why the algebra of quaternions is not commutative. Indeed, the vector rotations of the plan are commutative but those of space are not like show us the example below:

Given the initial configuration:

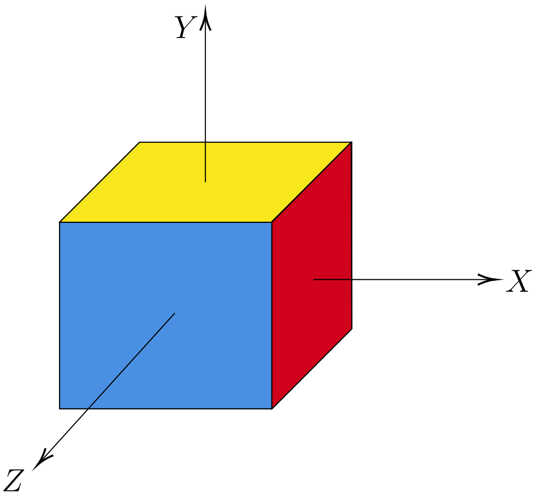

Figure 5.24: **Starting situation for quaternion rotations**

Then a rotation about the X-axis followed by a rotation around the Y axis:

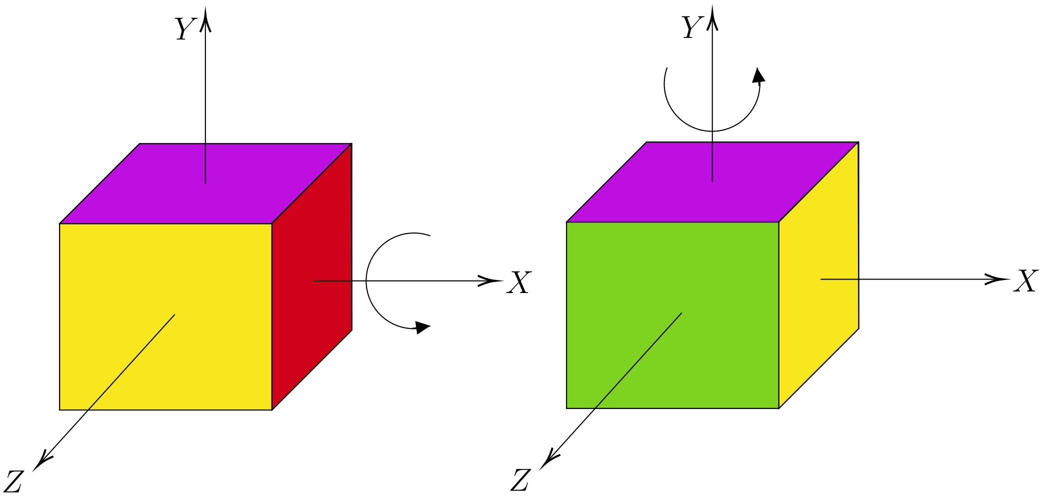

Figure 5.25: **Example quaternion $X - Y$ rotations**

is not equal to a rotation around the Y-axis followed by a rotation about the axis X:

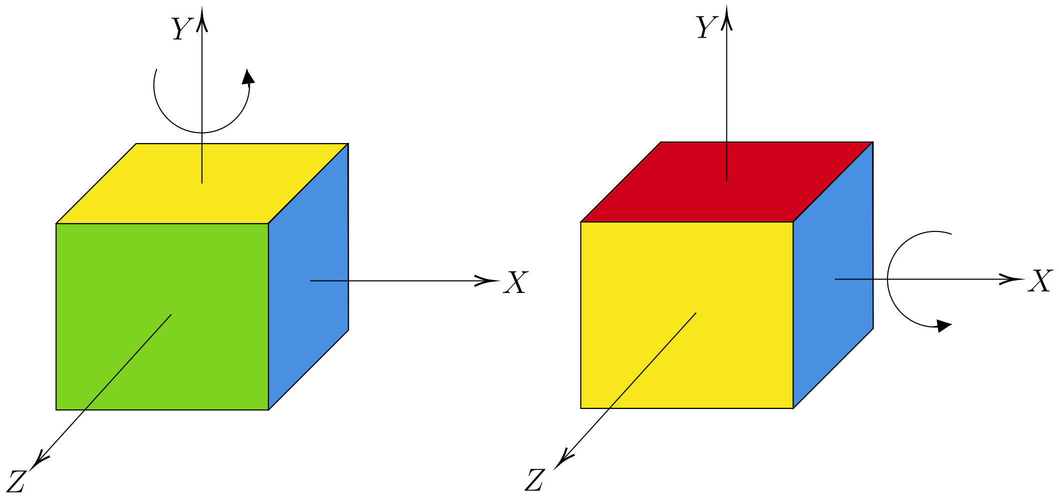

Figure 5.26: **Example of non-equivalence for quaternion rotation**

The results will be fundamental for our understanding of spinors (see section Spinor Calculus page 2145)!

> **Remark**
>
> Notice that we have (where $\mathbb{K}$ is a type of numbers named "Cayley numbers" that we have not planned to present in this book):
>
> $$\mathbb{R} \subset \mathbb{C} \subset \mathbb{H} \subset \mathbb{K} \tag{5.2.285}$$
>
> and that at each stage some element of abstract structure is lost. Ordering is lost on the passage from $\mathbb{R}$ to $\mathbb{C}$. Commutativity disappears on going from $\mathbb{C}$ to $\mathbb{H}$. The Cayley numbers $\mathbb{K}$ lose associativity.

5.2.2.9 Algebraic and Transcendental Numbers

Definitions (#5.2.43):

D1. We name "algebraic integer of degree n", any complex number that is a solution of an univariate algebraic equation of degree n, i.e. a polynomial of degree n (concept that we will discuss in the chapter of Algebra) whose coefficients are integers and whose dominant coefficient is equal to 1.

D2. We name "algebraic number of degree n", any complex number that is a solution of an univariate algebraic equation of degree n, i.e. a polynomial of degree n whose coefficients are rational.

The set of algebraic number is sometimes denoted by $\overline{\mathbb{Q}}$ or $\mathbb{A}$.

Theorem 5.8. A first interesting result and particularly in this area of study (mathematical curiosity...) is that a rational number is an "algebraic integer of degree n" if and only if it's an integer (read several times need...). In scientific terms, we the say that the ring $\mathbb{Z}$ is "fully closed".

Proof 5.8.1. We will assume that the number p/q , where p and q are two prime integers (that is to say that their ratio does not give an integer or more rigorously ... that the greatest common divisor of p,q is equal to 1! , is a root of the following polynomial (see section Calculus page 1368) with relative integer coefficients ($\in \mathbb{Z}$) and whose dominant coefficient is equal to 1:

$$x^n+a_{n-1}x^{n-1}+\ldots+a_1x+a_0 \tag{5.2.286}$$

where the equality with zero of the polynomial is implicit.

In this case:

$$p^n=-(a_{n-1}p^{n-1}+\ldots+a_1pq^{n-2}+a_0q^{n-1})q \tag{5.2.287}$$

Since the coefficients are by definition all integers and their multiple in the parenthesis also, then the parenthesis has necessarily a value in $\mathbb{Z}$.

Therefore, q (at the right of the parenthesis) divides a power of p (at the left of the equality), which is possible, in the set $\mathbb{Z}$ (because our bracket has a value in this same set for recall...), only if q is equal to ± 1 (as they were prime together).

So among all rational numbers the only that are solutions of polynomial equations with relative integer coefficients ($\in \mathbb{Z}$) for which the dominant coefficient is equal to 1 are relative integers!

■ Q.E.D.

To take another interesting and particular case, it is easy to show that any rational number is an algebraic number. Indeed, if we take the simplest following univariate polynomial:

$$qx-p=0 \tag{5.2.288}$$

where p and q are relatively prime and where q is different from 1. So as this is a simple polynomial with rational coefficients ($\in \mathbb{Q}$), after remaniment we have:

$$x=\frac{p}{q} \tag{5.2.289}$$

So since p and q are relatively prime and q is different from 1, we have indeed that every rational number is an "algebraic number of degree 1".

We also have the real (and irrational) number $\sqrt{2}$ which is an "algebraic integer of degree 2" because it is the root of:

$$x^2-2=0 \tag{5.2.290}$$

and the complex number i is also an "algebraic integer of degree 2" because it is the root of the equation:

$$x^2+1=0 \tag{5.2.291}$$

etc.

Definition (#5.2.44): A "transcendental number" is a real or complex number that is not algebraic. That is, it is not a root of a non-zero polynomial equation with rational coefficients.

Theorem 5.9. The set of all transcendental numbers is uncountable. The proof is simple and requires no difficult mathematical development.

Proof 5.9.1. Indeed, since the polynomial with integer coefficients are countable, and since each of these polynomials has a finite number of roots (see the Factorization Theorem in the section Calculus page 1377), the set of algebraic numbers is countable! But the argument of Cantor's diagonal (see section Set Theory page 225) states that real numbers (and therefore also the complex numbers) are uncountable, so the set of all transcendental numbers must be uncountable.

In other words, there is much more transcendental numbers than algebraic numbers...

■ Q.E.D.

The best known transcendent numbers are π and e. We are still looking to provide you a proof more nice and intuitive than that of Hilbert or Lindemann–Weierstrass.

5.2.2.10 Universe Numbers (normal numbers)

Definition (#5.2.45): A "Universe number" also named "normal number" is a real number whose infinite sequence of digits in every base b is distributed uniformly in the sense that each of the b digit values has the same natural density $1/b$. Intuitively this means that no digit, or (finite) combination of digits, occurs more frequently than any other. The set of Universe numbers is sometimes denoted $\mathbb{U}$.

While a general proof can be given that almost all purely real numbers are Universe numbers [181] this proof is not constructive and only very few specific numbers have been shown to be Universe numbers. It is widely believed that the (computable) numbers $\sqrt{2}$, π, and e are Universe numbers, but a proof remains elusive still in this year 12016 (holocene calendar). All of them however are strongly conjectured to be because of some empirical evidence. It is not even known whether all digits occur infinitely often in the decimal expansions of those constants. In particular, the popular claim "every string of numbers eventually occurs in π" or "the whole Holy book is contained in π is not known to be true. It has been conjectured that every irrational algebraic number is a Universe number, while no counterexamples are known, there also exists no algebraic number that has been proven to be a Universe number in any base.

More formally, let $\sum$ be a finite alphabet of b digits, and $\sum^\infty$ the set of all sequences that may be drawn from that alphabet. Let $S \in \sum^\infty$ be such a sequence. For each a in $\sum$ let $N_S(a,n)$ denote the number of times the letter a appears in the first n digits of the sequence S. We say that S is a "simple Universe number" if the limit:

$$\lim_{n\rightarrow+\infty}\frac{N_S(a,n)}{n}=\frac{1}{b} \qquad (5.2.292)$$

for each a is satisfied.

Now let w be any finite string in $\sum^*$ and let $N_S(w,n)$ to be the number of times the string w appears as a substring in the first n digits of the sequence S (for instance, if $S = 01010101\ldots$, then $N_S(010,8) = 3$). Then S is a "Universe number" if, for all finite strings $w \in \sum^*$:

$$\lim_{n\rightarrow+\infty}\frac{N_S(a,n)}{n}=\frac{1}{b^n} \qquad (5.2.293)$$

S is therefore a Universe number if all strings of equal length occur with equal asymptotic frequency. A given infinite sequence is either a Universe number or not, whereas a pure real number, having a different base-b expansion for each integer $b \geq 2$, may be a Universe number in one base but not in another. A "disjunctive sequence" is a sequence in which every finite string appears. A Universe number sequence is a "disjunctive sequence" but a disjunctive sequence need obviously not be a Universe number.

It is possible to prove (yet we don't wish not present this proof in a book on applied mathematics) with the "Universe number theorem" that almost all pure real numbers are Universe number. The set of non-Universe numbers, though "small" in the sense of being a null set, is "large" in the sense of being uncountable (for example no rational number is normal to any base, since the digit sequences of rational numbers are eventually periodic!). For instance, there are uncountable many numbers whose decimal expansion does not contain the digit 5, and none of these are Universe number.

5.2.2.11 Abstract Numbers (variables)

Definition (#5.2.46): A number may be considered as doing abstraction from the nature of the objects that constitute the group that it characterizes as well as how to codify it (Indian notation, Roman notation, etc.). We then say that the number is an "abstract number". In other words, an abstract number, is a number that does not designate the quantity of any particular kind of thing.

Remark

Arbitrarily, the human being has adopted a numerical system mainly used in the World and represented by the symbols $0, 1, 2, 3, 4, 5, 7, 8, 9$ of the decimal system that will be supposedly known both in writing than orally by the reader (language learning).

For mathematicians, it is not advantageous to work with these symbols because they represent only specific cases. What seek theoretical physicists and mathematicians are "literal relations" applicable in a general case and that engineers can according to their needs change these abstract numbers by numeric values that correspond to the problem they need resolve.

These abstract numbers today commonly named "variable" or "unknown", used in the context of "literal calculation" are very often represented since the 116th century (holocene calendar) by:

1. The Latin alphabet:

$$a, b, c, d, e, \ldots, x, y, z; A, B, C, D, E, \ldots, X, Y, Z$$

   where the first lower case letters of the latin alphabet ($a, b, c, d, e \ldots$) are often used to represent an abstract constant, while the lowercase letters of the end of the latin alphabet ($\ldots, x, y, z$) are used to represent entities (variables or unknowns) we seek the value. Commonly, uppercase latin letters are reserved to represent matrices or random variables.

2. The Greek alphabet:

$\mathrm{A}\alpha$	Alpha	$\Lambda\lambda$	Lambda
$\mathrm{B}\beta$	Beta	$\mathrm{M}\mu$	Mu
$\Gamma\gamma$	Gamma	$\mathrm{N}\nu$	Nu
$\Delta\delta$	Delta	$\Xi\xi$	Xi
$\mathrm{E}\epsilon\varepsilon$	Epsilon	$\mathrm{O}o$	Omicron
$\mathrm{Z}\zeta$	Zeta	$\Pi\pi$	Pi
$\mathrm{H}\eta$	Eta	$\mathrm{P}\rho$	Rho
$\Theta\theta\vartheta$	Theta	$\Sigma\sigma$	Sigma
$\mathrm{I}\iota$	Iota	$\mathrm{T}\tau$	Tau
$\mathrm{K}\kappa$	Kappa	$\Upsilon\upsilon$	Upsilon
$\Phi\phi\varphi$	Phi	$\mathrm{X}\chi$	chi
$\Psi\psi$	Psi	$\Omega\omega$	Omega

Table 5.17: **Greek Alphabet**

   which is particularly used to represent more or less complex mathematical operators (such as the index sum Σ, the indexed product Π, the variational δ, the infinitesimal element ε, partial differential ∂, etc.) or variables in the field of physics (as ω for the pulsation, ν for the frequency, ρ for the density, etc.).

3. The modernized Hebrew alphabet (with less intensity...)

   As we have seen, a transfinite cardinal for example is denoted by the letter "aleph": $\aleph_0$.

Although these symbols can represent any number there are some who can represent physical constants also named "Universal constant" as the speed of light c, the gravitational constant G, the Planck constant h, the number π, etc.

We use very often still other symbols that we will introduce and define when reading this book.

Remark

The letters to represent numbers had been used for the first time by Vieta in the 116th century (holocene calendar).

5.2.2.11.1 Domain of a Variable

A variable is therefore likely to take different numerical values. All these values can vary according to the character of the problem considered.

Given two numbers a and b such that $a < b$, then:

Definitions (#5.2.47):

D1. We name "domain of definition" of a variable, all numerical values it is likely to take between two specified limits (endpoints) or on a set (like $\mathbb{N},\mathbb{R},\mathbb{R}^+$, etc.).

D2. We name "closed interval with endpoints a and b", the set of all numbers x between these two values and we denote as example as follows:

$$[a,b]=\{x\in\mathbb{R}\mid a\leq x\leq b\} \tag{5.2.294}$$

The left notation is named obviously "interval notation", the right one is named "set-builder notation".

D3. We name "open interval with endpoints a and b", the set of all numbers x between these two values not included and we denote it as example as follows:

$$]a,b[=\{x\in\mathbb{R}\mid a< x< b\} \tag{5.2.295}$$

D4. We name "interval closed, left open right" or "semi-closed left" the following relation as example:

$$[a,b[=\{x\in\mathbb{R}\mid a\leq x< b\} \tag{5.2.296}$$

D5. We name "interval open left, closed right" or "semi-closed right" the following relation as example:

$$]a,b]=\{x\in\mathbb{R}\mid a< x\leq b\} \tag{5.2.297}$$

Or in a summary and imaged form and as often denoted in Switzerland:

Type	Visual	Math notation	Explicitly
$[a,b]$		$a \leq x \leq b$	Closed bounded interval
$[a,b[$		$a \leq x < b$	Semi-closed and bounded interval on a and semi-open on b (or left semi-closed and right semi-open)
$]a,b]$		$a < x \leq b$	Semi-open bounded interval on a and semi-closed on b (or left semi-open and right semi-closed)
$]a,b[$		$a < x < b$	Bounded open interval
$]-\infty,b]$		$x \leq b$	Unbounded interval closed on b (or closed right)
$]-\infty,b[$		$x \leq b$	Unbounded interval open on b (or open right)
$[a,+\infty[$		$a \leq x$	Unbounded interval closed on a (or closed left)
$]a,+\infty[$		$a < x$	Unbounded interval open on a (or open left)

Table 5.18: **Summary of typical domain of definitions in Switzerland**

and according to the international norm ISO 80000-2:2009 *Mathematical signs and symbols to be used in the natural sciences and technology* (since Switzerland is quite good in the no respect of international norms and standards):

Type	Visual	Math notation	Explicitly
$[a,b]$		$a \leq x \leq b$	Closed bounded interval
$[a,b)$		$a \leq x < b$	Semi-closed and bounded interval on a and semi-open on b (or left semi-closed and right semi-open)
$(a,b]$		$a < x \leq b$	Semi-open bounded interval on a and semi-closed on b (or left semi-open and right semi-closed)
(a,b)		$a < x < b$	Bounded open interval
$(-\infty,b]$		$x \leq b$	Unbounded interval closed on b (or closed right)
$(-\infty,b[$		$x \leq b$	Unbounded interval open on b (or open right)
$[a,+\infty)$		$a \leq x$	Unbounded interval closed on a (or closed left)
$(a,+\infty)$		$a < x$	Unbounded interval open on a (or open left)

Table 5.19: Summary of typical domain of definitions according to ISO norms

Remarks

R1. The notation $\{x \text{ such that } a < x < b\}$ denotes the set of real numbers x strictly greater than x and strictly less than b.

R2. To fact that an interval is for example opened on b means that the real number b is not part thereof. By cons, if it had been closed then b would be part of it.

R3. If the variable x can take all possible negative and positive values we write therefore: $]-\infty,+\infty[$ where the symbol "∞" means "infinite". Obviously there can be combinations of open infinite right intervals with left endpoint and vice versa.

R4. We will recall some of these concepts with a different approach when studying Algebra (literal calculation).

We say that the variable x is an "ordered variable" if by representing its domain of definition by a horizontal axis where each point on the axis represents a value of x, then for each pair of values, we can say that there is an "antecedent" and one that is a "subsequent". Here the notion of antecedent and subsequent is not related to the concept of time it expresses just how the values of the variable are ordered.

Definitions (#5.2.48):

D1. A variable is said to be "increasing" if each subsequent value is greater than each antecedent value.

D2. A variable is said to be "decreasing" if each subsequent value is smaller than each antecedent value.

D3. The increasing and decreasing variables are named "variables with monotonic variations" or simply "monotonic variables".

5.3. Arithmetic Operators

TALKING about numbers like we did in the previous section naturally leads us to consider the operations of calculus. It is therefore logic that we make a non-exhaustive description of the operations that may exist between the numbers. This will be the goal of this section.

We will consider in this book that there are two types of key tools in Arithmetics (we do not speak of Algebra but Arithmetic!):

- Arithmetic operators:

  There are two basic operators (addition "$+$" and subtraction "$-$") from which we can build other operators: the "multiplication" (whose contemporary symbol $\times$ was introduced in 11574 - according to holocene calendar - by William Oughtred) and the "division" (whose old symbol was "$\div$" but since the end of the 120th century (holocene calendar) we use simple the slash $/$ symbol).

  These four operators $(+, -, \times, /)$ are commonly named "rational operators". We will see them more in details after setting the binary relations.

  Remark

  Rigorously addition could be enough if we consider the common set of real number $\mathbb{R}$ because therefore the subtraction is only the addition of a negative number.

- Binary operators (relations):

  There are six basic binary relations (equal $=$, different $\neq$, greater than $>$, less than $<$, greater or equal $\geq$, less than or equal $\leq$) that compare the order of amplitude of elements that are on the left and on the right of these relations (thus at the number of two, hence the name "binary") in order to draw some conclusions. The majority of binary relations symbols were introduced by Vieta and Harriot in the 116th century (holocene calendar).

It is obviously essential to know as best a possible these tools and their properties before going through into more strenuous calculations.

5.3.1 Binary Relations

The concept of "relation" is the basis of all mathematics whose purpose is to study - by observation and deduction (reasoning), calculation and comparison - configurations or abstract/concrete relations of its objects (numbers, forms, structures) by seeking to establish the logical, numerical or conceptual links between these objects.

Definitions (#5.3.49):

D1. Consider two non-empty sets E and F (see section Set Theory page 383) not necessarily identical. If to some given elements x of A we can associate with a precise mathematical rule $\mathcal{R}$ (unambiguous) one element y of F, we define therefore a "functional relation" that maps E to F and that we write:

$$\mathcal{R} : E \mapsto F \tag{5.3.1}$$

Thus, more generally, a functional relation $\mathcal{R}$ can be defined as a mathematical rule that associates to given components x of E, some given elements y of F.

So, in this more general context, if $x\mathcal{R}y$, we say that there y is an "image" of x through $\mathcal{R}$ and that x is a "precedent" or "preimage" of y.

The set of pairs (x, y) such that $x\mathcal{R}y$ is a true statement generates a "graph" or "representation" of the relation $\mathcal{R}$. We can represent these couples in a proper chosen way to make a graphical representation of the relation $\mathcal{R}$.

This is a type of relation on which we will come back in the section Functional Analysis (page 2214) under the form: $\mathcal{R} : f(x) = y \circ f$ and that does not interest us directly in this section.

D2. Consider a non-empty set E, if we associate with this set (and only to this one!) tools to compare its items between them then we talk about a "binary relation" or "comparison relation" and that we write for any element x and y of E:

$$x\mathcal{R}y \tag{5.3.2}$$

These relations can also most of time be presented graphically. In the case of conventional binary operators comparison where E is the set of natural numbers $\mathbb{N}$, relative $\mathbb{Z}$, rationals $\mathbb{Q}$ or real $\mathbb{R}$, that is graphically represented by a horizontal line (typically...); in the case of congruence (see section Number Theory page 356) it is represented by lines in the plane whose points are given by the constraint of congruence.

As we already mentioned, there are 6 fundamental binary relationships (equal $=$, different from $\neq$, greater than $>$, smaller than $<$, bigger or equal $\geq$, smaller or equal $\leq$). But we will see a little further that the rigorous definition of binary relations allows us to build more abstract tools (such as congruence well known by students of small classes and that we will study in the section of Number Theory).

5.3.1.1 Equalities

It is difficult to define the term "equality" in a general case applicable to any situation. For our part, we will allow ourselves for this definition to take the inspiration of the extensionality axiom of Set Theory (discussed later at page 382).

Definitions (#5.3.50):

D1. Two elements are "equal" if and only if they have the same values. The strict equality is denoted by the symbol $=$ that therefore means "equal to" (this symbol was introduced in 11557 - according to holocene calendar - by Robert Rocorde).

If we have $a = b$ and c is any given number (or vector/matrix) and $\star$ any operation (such as addition, subtraction, multiplication or division) then:

$$a \star c = b \star c \tag{5.3.3}$$

This property is used to solve or simplify any type of equations. In practice, the abbreviation "LHS" is informal shorthand for the left-hand side of an equality. Similarly, "RHS" is the right-hand side abbreviation of that latter.

Obviously we have (property of reflexivity):

$$a = b \Leftrightarrow b = a \tag{5.3.4}$$

And also (property of transitivity):

$$\left.\begin{array}{l} a = c \\ b = c \end{array}\right\} a = b$$

We will not enumerate the other properties of the equality in this section (for more details see the section Set Theory page 287).

D2. If two elements are not strictly equal, that is to say "inequal"..., we are connecting them by the symbol $\neq$ and we say they are "not equal".

If we have $a > b$ or $a < b$ then:

$$a \neq b \tag{5.3.5}$$

There are still other equality symbols, which are an extension of two we have defined previously. Unfortunately, they are often misused (we could say rather that they are used in the wrong places) in most of the books available on the market (and this book is not an exception):

1. $\cong$: Should be used for congruence but in fact is mostly used to indicate an approximation.
2. $\approx$: Should be used for approximations but in fact $\cong$ is used instead.
3. $\equiv$: Should be used to say that two elements are equivalent but in practice most people use $=$.

4. $:=$: Is used to say that one element is by definition equal to another one.

5. $\doteq$: Should be used to say "equal by definition to" but in fact most people use instead $:=$.

6. $\sim$: Is used most of time in Statistics to say "follows the law..." but some practitioners use instead $=$ or to say "asymptotically equal".

5.3.1.2 Comparators

The comparators are tools that allow us to compare and order any pair of numbers (and also Sets!).

The possibility of ordering numbers is fundamental in mathematics. Otherwise (if it was not possible to order them), there would be a lot of things that would shock our habits, for example (some of the concepts presented in the following sentence have not yet been presented but we would still make reference to them): no more monotonic functions (especially sequences) and linked to it the derivation would therefore indicate nothing more about the "variation direction", no more approach of roots of polynomial by dichotomy (classical research algorithm in an ordered set that split in two at each iteration), no more segments in geometry, no more than half space, no more convexity, we can not oriented space anymore, etc. It is therefore important to be able to order things as you can see...!

Thus, for any $a, b, c \in \mathbb{R}$ we write when a is greater than or equal to b:

$$a \geqslant b \tag{5.3.6}$$

and when a is less than or equal to b:

$$a \leqslant b \tag{5.3.7}$$

Remark

It is useful to recall that the set of real numbers $\mathbb{R}$ is a totally ordered group (see section Set Theory page 421), otherwise we could not establish order relations among its elements (which is not the case for complex numbers $\mathbb{C}$ that we can not order!).

Definition (#5.3.51): The symbol $\leq$ is an "relation order" (see the rigorous definition further below!) which means "less than or equal to" and conversely the symbol $\geq$ is also an order relation that means "greater than or equal to".

We also have relatively to the strict comparison the following properties that are relatively intuitive:

$$\begin{aligned} a<b \quad &\text{and} \quad b<c \quad \Rightarrow \quad a<c \\ a>b \quad &\text{and} \quad b>c \quad \Rightarrow \quad a>c \end{aligned} \tag{5.3.8}$$

and:

$$\begin{aligned} a>b \quad &\text{and} \quad b=c \quad \Rightarrow \quad a>c \\ a<b \quad &\text{and} \quad b=c \quad \Rightarrow \quad a<c \end{aligned} \tag{5.3.9}$$

if:

$$a < b \quad \text{and} \quad c > 0 \quad \Rightarrow \quad ac < bc \tag{5.3.10}$$

if:

$$a < b \Rightarrow a + c < b + c \qquad \text{and} \qquad a < b \Rightarrow a - c < b - c \tag{5.3.11}$$

and vice versa:

$$a > b \Rightarrow a + c > b + c \qquad \text{and} \qquad a > b \Rightarrow a - c > b - c \tag{5.3.12}$$

We also have:

$$0 < a < b \Rightarrow \frac{1}{a} > \frac{1}{b} \tag{5.3.13}$$

and vice versa:

$$b < a < 0 \Rightarrow \frac{1}{a} < \frac{1}{b} \tag{5.3.14}$$

We can obviously multiply, divide, add or subtract a term from each side of the relation as it is always true. Notice, however, that if you multiply both sides by a negative number it will obviously change as the comparator such that:

$$a > b \quad \text{and} \quad c > 0 \quad \Rightarrow \quad ac < bc \tag{5.3.15}$$

and vice versa:

$$a < b \quad \text{and} \quad c < 0 \quad \Rightarrow \quad ac > bc \tag{5.3.16}$$

We also have:

$$0 < a < b \quad \text{and} \quad p \in \mathbb{R}^{*+} \quad \Rightarrow \quad a^p < b^p \tag{5.3.17}$$

Consider now that $b < a < 0$ and $p \in \mathbb{N}^*$. Then if p is an even integer:

$$0 < a^p < b^p \tag{5.3.18}$$

else if p is odd:

$$a^p > b^p \tag{5.3.19}$$

This result simply comes from the multiplication of signs rule since the power when not fractional is only a multiplication.

Finally:

$$0 < a < b \quad \text{and} \quad n \in \mathbb{N}^* \quad \Rightarrow \quad \sqrt[n]{a} < \sqrt[n]{b} \tag{5.3.20}$$

The relations:

$$\boxed{> \quad < \quad \leqslant \quad \geqslant \quad \gg \quad \ll} \tag{5.3.21}$$

thus correspond respectively to: (strictly) greater than, (strictly) smaller than, smaller or equal, greater or equal, much bigger than, much smaller than.

These relations can be defined in a little more subtle and rigorous way and apply not only to comparators (see for example the congruence relation in the section of Set Theory page 356)!

Let us see this (the vocabulary that follows is also defined in the section of Set Theory page 406):

Definition (#5.3.52): Given a binary relation $\mathcal{R}$ of a set A to itself, a relation R on A is a subset of the Cartesian product $\mathcal{R} \subseteq A \times A$ (that is to say, the binary relation generates a subset by the constraints it imposes on the elements of A satisfying the relation) with the property of being:

P1. A "reflexive relation" if $\forall x \in A$:

$$x\mathcal{R}x \tag{5.3.22}$$

P2. A "symmetrical relation" if $\forall x, y \in A$:

$$x\mathcal{R}y \Rightarrow y\mathcal{R}x \tag{5.3.23}$$

P3. An "anti-symmetrical relation" if $\forall x, y \in A$:

$$(x\mathcal{R}y \quad \text{and} \quad y\mathcal{R}x) \Rightarrow x = y \tag{5.3.24}$$

P4. A "transitive relation" if $\forall x, y, z \in A$:

$$(x\mathcal{R}y \quad \text{and} \quad y\mathcal{R}z) \Rightarrow x\mathcal{R}z \tag{5.3.25}$$

P5. An "connex relation" if $\forall x, y \in A$:

$$\forall x, y \in A \Rightarrow x\mathcal{R}y \quad \text{or} \quad y\mathcal{R}x \tag{5.3.26}$$

Mathematicians have given special names to the families of relations satisfying some of these properties.

Definitions (#5.3.53):

D1. A relation is named "strict order relation" if and only if it is only transitive (some specify then that it is necessarily antireflexive but this last fact is then obvious...).

D2. A relation is named a "preorder" if and only if it is reflexive and transitive.

D3. A relation is named an "equivalence relation" if and only if it is reflexive, symmetric, and transitive.

D4. A relation is named "order relation" if and only if it is reflexive, transitive and antisymmetric (thus the relations $>, <$ are not order relations because obviously not reflexive relations).

D5. A relation is named "total order relation" if and only if it is reflexive, transitive, connex and antisymmetric.

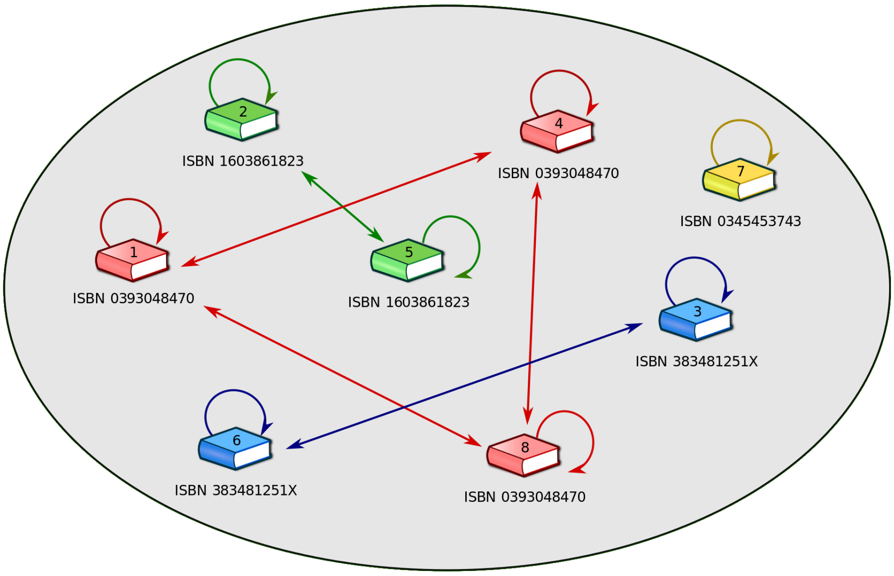
For the other combinations it seems (as far as we know) that there are no special name among the mathematicians...

Remark

The binary relations have all similar properties in natural sets $\mathbb{N}$, relative $\mathbb{Z}$, rational $\mathbb{Q}$ and real $\mathbb{R}$ (there is no natural order relation on the set of complex numbers $\mathbb{C}$).

✍**Example:**

Of the below set of eight copies of books, the relation "... has the same ISBN as ..." is an equivalence relation:



2
ISBN 1603861823
4
ISBN 0393048470
7
ISBN 0345453743
1
ISBN 0393048470
5
ISBN 1603861823
3
ISBN 383481251X
6
ISBN 383481251X
8
ISBN 0393048470

Figure 5.27: **Illustration of an equivalence relation (source: Wikipedia, author: Stephan Kulla)**

If we summarize:

BINARY RELATION	$=$	$\neq$	$>$	$<$	$\leqslant$	$\geqslant$
reflexive	yes	no	no	no	yes	yes
symmetric	yes	yes	no	no	no	no
transitive	yes	no	yes	yes	yes	yes
connex	no	no	no	no	yes	yes
antisymmetric	yes	no	no	no	yes	yes

Table 5.20: **Binary Relations**

Thus we see that the binary relations $\leq, \geq$ form with the previously mentioned sets, total order relations and it is very easy to see which binary relations are partial, total or equivalence order relations.

Definition (#5.3.54): If $\mathcal{R}$ is an equivalence relation on A. For $\forall x \in A$, the "equivalence class" of x is by definition the set:

$$\boxed{[x] = \{y \in A : x\mathcal{R}y\}} \tag{5.3.27}$$

$[x]$ is therefore a subset of A ($x \subseteq A$) which we denote also thereafter ... R.

We thus have a new set that is named the "set of equivalence classes" or "quotient set" denoted in this book by A/R. So:

$$\boxed{A/\mathcal{R} = \{[x] | x \in A\}} \tag{5.3.28}$$

You should know that in $A/\mathcal{R}$ we do not look anymore at $[x]$ as a subset of A, but as an element!

A relation of equivalence, presented in a popularized manner... thus serves to stick one unique label to items that satisfy the same property, and to confuse them with the said label (knowing what we do with this label).

✍**Examples:**

E1. Set of the classes of equivalence of the previously illustration about the ISBN:

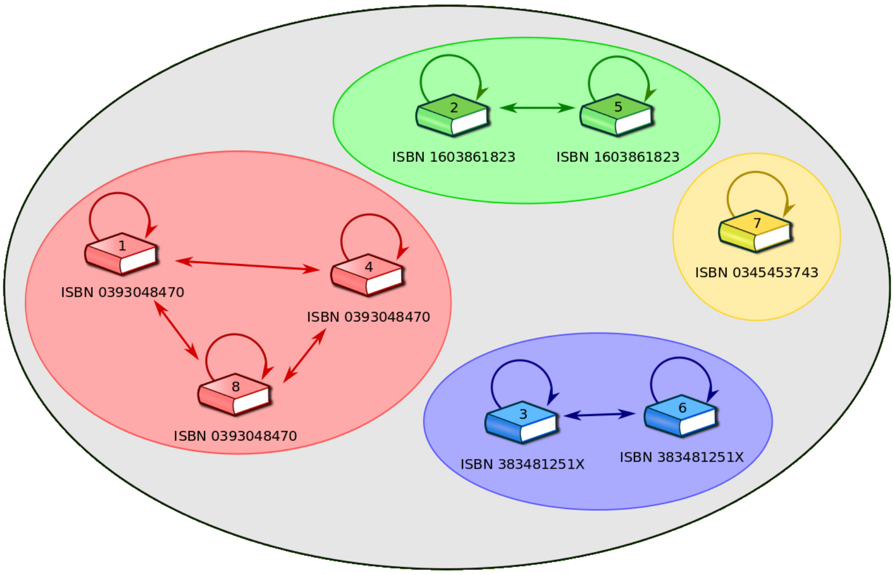


Figure 5.28: **Illustration of set of equivalence classes (source: Wikipedia, author: Stephan Kulla)**

E2. In the set of integers $\mathbb{Z}$, if we study the remains of the division of number by 2, we have that the result is always 0 or 1.

The zero equivalence class is then named the "set of even integers numbers", the one equivalence class is therefore named the "set of odd integers". So we have two classes of equivalence for two partitions of $\mathbb{Z}$ (always keep in mind this simple example for theoretical elements that follow it helps a lot!).

If we name the first 0 and the second 1, we fall back on the operation rules between odd and even numbers:

$$0+0=0 \qquad 0+1=0 \qquad 1+1=0$$

which respectively means that the sum of two even integers is even, that the sum of an even and an odd integer is odd and that the sum of two odd integer is even.

And for the multiplication:

$$0\times 0=0 \qquad 0\times 1=0 \qquad 1\times 1=1$$

which respectively means that the two product of two even integer is even, the product of an even and an odd integer is even and that the product of two odd integer is odd.

Now, to verify that we are dealing with an equivalence relation, we should still check that it is reflexive ($x\mathcal{R}x$), symmetrical (if $x\mathcal{R}y$ then $y\mathcal{R}x$) and transitive (if $x\mathcal{R}y$ and $y\mathcal{R}z$ then $x\mathcal{R}z$). We will see how to check it a few paragraphs further below because this example is a very special case of congruence relation.

Definition (#5.3.55): The application $f: A \mapsto A/\mathcal{R}$ defined by $x \mapsto [x]$ is named "canonical projection". Any element $z \in [x]$ is therefore named "class representative" of $[x]$.

Theorem 5.10. Now consider a set E. Then we propose to proved that there is correspondence between the set of equivalence relations on E and all partitions of E. In other words, this theorem says that an equivalence relation on E is nothing more but a partition on E (this is intuitive).

Proof 5.10.1. Let $\mathcal{R}$ be an equivalence relation on E. We choose $I = E/\mathcal{R}$ as set partition indexing and all we ask for any $[x] \in E/\mathcal{R}$, $E_{[x]} = [x]$.

We just have to check the following two properties of the definition of partitions to show that the family $\left(E_{[x]}\right)_I$ is a partition of E:

P1. Given $[x],[y] \in E/\mathcal{R}$ such that $[x] \neq [y]$ then (obvious) $E_{[x]} \cap E_{[y]} = \varnothing$.

P2. $E = \bigcup\limits_{[x]\in E/\mathcal{R}}$ is obvious because if $x \in E$ then $x \in [x] = E_{[x]}$.

■ Q.E.D.

Again, it should by easy to check with the practical example of the division by 2 given previously that the partition of even and odd numbers satisfies these two properties (if not reader can contact us we will add this as an example).

We have therefore associated to the equivalence relation $\mathcal{R}$ a partition E. Conversely, if $(E_i)_I$ is a partition of E then we almost easily verify that the relation $\mathcal{R}$ is defined by $x\mathcal{R}y$ if and only if there exists $i \in I$ such as $x, y \in E_i$ is an equivalence relation! Both applications are thus bijective and the inverses of each other.

✍**Example:**

We will now apply an example a little less trivial than the last we have seen to the construction of rings $\mathbb{Z}/d\mathbb{Z}$ after a few reminders equation (for the concept of ring see the section Set Theory page 426).

Reminders:

1. Given two numbers $n, m \in \mathbb{Z}$. We say that "n divides m" and we write $n|m$ if and only if there exists an integer $k \in \mathbb{Z}$ such as $m = kn$ (see section Numbers Theory page 313).
2. Given $d \geq 1$ is an integer. We define the relation $\mathcal{R}$ by $n\mathcal{R}m$ if and only if $d|(n-m)$ or in other words $n\mathcal{R}m$ if and only if there exists $d \in \mathbb{Z}$ such that $n = m + kd$. Usually we write this $n \equiv m \pmod{d}$ instead of $n\mathcal{R}m$ and we say that "n is congruent to m modulo d". Remember also that $n \equiv 0 \pmod{d}$ if and only if d divides n (see section Numbers Theory page 356).

We will now introduce an equivalence relation on $\mathbb{Z}$. Let us prove that for any integer $d \geq 1$, the congruence modulo d is an equivalence relation on $\mathbb{Z}$ (we have already proved this in the section of Number Theory in our study of congruence on page 356, but let us redo this work for the fun...).

To prove this we simply have to control the three properties of the equivalence relation:

P1. Reflexivity: $n \equiv n$ since $n = n + 0d$.

P2. Symmetry: If $n \equiv m$ then $n = m + kd$ and therefore $m = n + (-k)d$ that is to say $m \equiv n$.

P3. Transitivity: If $n \equiv m$ and then $m \equiv j$ then $n = m + kd$ and $m = j + k'd$ therefore $n = j + (k + k')d$ that is to say $n \equiv j$.

In the above situation, we denote by $\mathbb{Z}/d\mathbb{Z}$ the set of equivalence classes and we will denote by $[n]_d$ the equivalence class of congruence of a given integer n given by:

$$[n]_d = \{\ldots, n-2d, n-d, n, n+d, n+2d, n+3d, \ldots\} \tag{5.3.29}$$

(each difference of two values in the braces is divisible by d and this is therefore an equivalence class), thus:

$$\mathbb{Z}/d\mathbb{Z} = \{[0]_d, [1]_d, [2]_d, \ldots, [d-1]_d\} \tag{5.3.30}$$

In particular (trivial since we obtain thus the all $\mathbb{Z}$):

$$\mathbb{Z}/2\mathbb{Z} = \{[0]_2, [1]_2\} \tag{5.3.31}$$

Thus, we see that the first example we gave with the even and odd numbers is a particularly simple case of congruence equivalence classes modulo 2 because they all reduce to only two classes.

Remark

The operations of addition and multiplication on $\mathbb{Z}$ define also the operation of addition and multiplication on $\mathbb{Z}/d\mathbb{Z}$. Then we say that these operations are compatible with the equivalence relation and then form a ring (see section Set Theory page 426).

5.3.2 Fundamental Arithmetic Laws

As we have said before, there is a fundamental operator (addition) from which we can define multiplication, subtraction (provided that the chosen Numbers Set is adapted to it....) and division (provided that the chosen Numbers Set is also adapted to it....) and around which we can build the entire Analytical Mathematics.

Obviously there are some subtleties to be considered when the level of rigour increase. The reader can then refer to the whole section of Set Theory (page 378) where fundamental laws are redefined more accurately than what will follow.

5.3.2.1 Addition

Definition (#5.3.56): The "addition" of integers is an operation denoted "$+$" which has for only purpose to bring together in one number all the units contained in several others. The result of the operation is named the "sum", the "total" or "cumul". The numbers to be added are named therefore "terms of the addition".

Remark

The signs of addition "$+$" and subtraction "$-$" are due to the German mathematician Johannes Widmann (11489 according to holocene calendar).

Thus, $A + B + C\ldots$ are the terms of the addition and the result is the sum of the terms of the addition.

Or in schematic form of a special case:

$$0+4+3=4+3=7$$

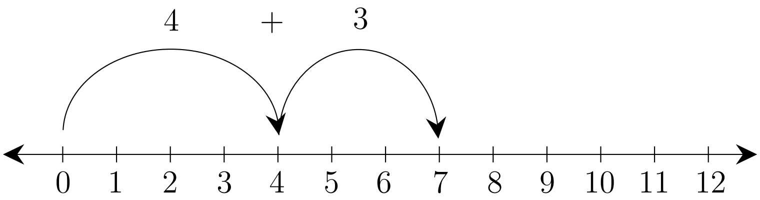

Figure 5.29: **One possible schema for addition**

Here is a list of some intuitive properties that we assume without proofs (as in fact they are axioms) of the operation of addition:

P1. The sum of several numbers do not depend on the order of terms. Then we say that the addition is a "commutative operation". This means concretely for any two numbers:

$$A+B=B+A \tag{5.3.32}$$

P2. The sum of several numbers does not change if we replace two or more of them by their intermediate result. Then we say that the addition is an "associative operation":

$$(A+B)+C=A+(B+C) \tag{5.3.33}$$

P3. The Zero is the neutral element of addition because any number added to zero gives that number:

$$A+0=0 \tag{5.3.34}$$

P4. Depending on the set in which we work ($\mathbb{Z},\mathbb{Q},\mathbb{R},\ldots$), the addition may include a term in such a way that a sum is zero. Then we say that there exists an "opposite" to the sum such as:

$$A+\bar{A}=0 \tag{5.3.35}$$

We have define more rigorously the addition using the Peano axioms in the particular case of all natural numbers $\mathbb{N}$ as we have already see in the section Numbers (page 215). So, with these axioms it is possible to prove that there exists one and only one application (uniqueness), denoted "+" of $\mathbb{N}\times\mathbb{N}$ in $\mathbb{N}$ satisfying:

$$\begin{aligned}
\forall n\in\mathbb{N}: &\quad n+0=n\\
\forall p\in\mathbb{N},\forall q\in\mathbb{N}: &\quad p+s(q)=s(p+q)\\
\forall n\in\mathbb{N}: &\quad s(n)=n+1
\end{aligned} \tag{5.3.36}$$

where s means "successor".

Remark

As this textbook has not be written for mathematicians, we will pass the proof (relatively long and of little interest in the case of business) and we will assume that the application "+" exists and is unique ... and that it follows from the above properties.

Let $x_1, x_2, \ldots, x_n$ be any numbers then we can write the sum as following:

$$\boxed{x_1 + x_2 + \ldots + x_n = \sum_{i=1}^{n} x_i} \tag{5.3.37}$$

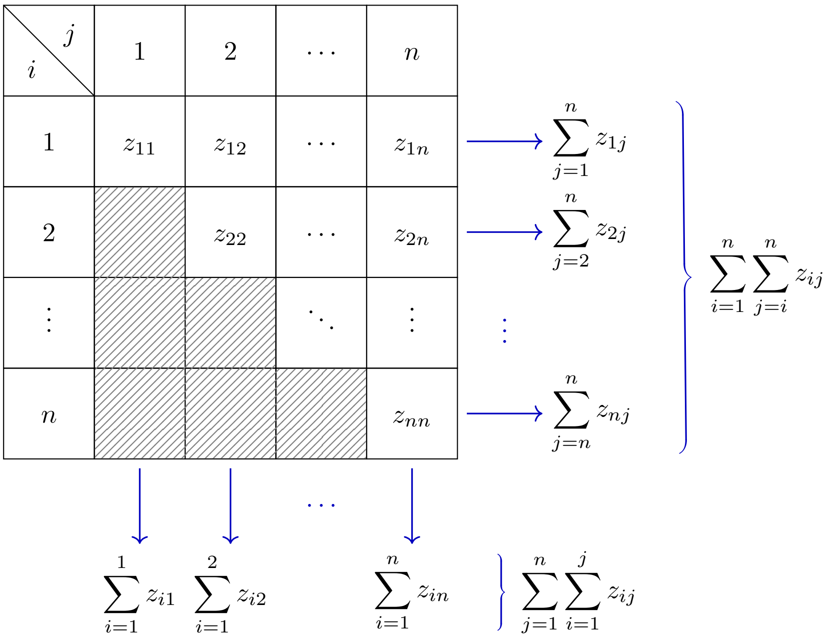
by defining upper and lower bound to the indexed sum (below and above the uppercase greek symbol Sigma).

Here are some properties relatively to this condenses notation that should be obvious (if not the reader can send us a request we will add the details):

$$\sum_{i=1}^{n} kx_i = k\sum_{i=1}^{n} x_i \qquad \sum_{i=1}^{n} k = nk \qquad \sum_{i=1}^{n}(x_i + y_i) = \sum_{i=1}^{n} x_i + \sum_{i=1}^{n} y_i \tag{5.3.38}$$

where k is a constant.

Such a notation is especially useful when we have to sum for example double entry tables like the special case illustrated below (symmetric square matrix):



j
i
1
2
$\cdots$
n
1
z_{11}
z_{12}
$\cdots$
z_{1n}
2
z_{22}
$\cdots$
z_{2n}
$\vdots$
$\ddots$
$\vdots$
n
z_{nn}
$\sum_{j=1}^{n} z_{1j}$
$\sum_{j=2}^{n} z_{2j}$
$\vdots$
$\sum_{j=n}^{n} z_{nj}$
$\sum_{i=1}^{n}\sum_{j=i}^{n} z_{ij}$
$\sum_{i=1}^{1} z_{i1}$
$\sum_{i=1}^{2} z_{i2}$
$\cdots$
$\sum_{i=1}^{n} z_{in}$
$\sum_{j=1}^{n}\sum_{i=1}^{j} z_{ij}$

Let us see now some concrete examples of additions of various simple number in the purpose to practice the basis:

✍**Examples:**

The addition of two numbers relatively small is quite easy since we have learn by heart to count to a number resulting of the operation. Therefore (examples taken on decimal basis):

$$\begin{array}{rr} & 5 \\ + & 2 \\ \hline & 7 \end{array} \tag{5.3.39}$$

and:

$$\begin{array}{rcc} & 1 & 0 \\ + & & 3 \\ \hline & 1 & 3 \end{array} \tag{5.3.40}$$

and:

$$\begin{array}{rcccc} & 1 & 0 & 1 & 4 \\ + & & & & 3 \\ \hline & 1 & 0 & 1 & 7 \end{array} \tag{5.3.41}$$

For more bigger number we can adopt another method that human must also learn by heart. For example:

$$\begin{array}{rcccc} & 9 & 2 & 4 & 4 \\ + & 3 & 4 & 7 & 5 \\ \hline & & & & ? \end{array} \tag{5.3.42}$$

The algorithm (process) is therefore the following: We add the columns (4 columns in this example) from right to left. For the first column we have therefore $4+5=9$ this gives:

$$\begin{array}{rcccc} & 9 & 2 & 4 & 4 \\ + & 3 & 4 & 7 & 5 \\ \hline & & & & 9 \end{array} \tag{5.3.43}$$

and we continue like this for the second column where we have $4+7=11$ at the difference that now we have a number >10, then we report the first left digit on the next (left) column for the addition. Therefore:

$$\begin{array}{rcccc} & 9 & 2^{+1} & 4 & 4 \\ + & 3 & 4 & 7 & 5 \\ \hline & & & 1 & 9 \end{array} \tag{5.3.44}$$

The third column we be calculated therefore as $1+2+4=7$ which give us:

$$\begin{array}{rcccc} & 9 & 2^{+1} & 4 & 4 \\ + & 3 & 4 & 7 & 5 \\ \hline & & 7 & 1 & 9 \end{array} \tag{5.3.45}$$

For the last column we have $9+3=12$ and once again we report the first digit from the left on the next column of the addition. Therefore:

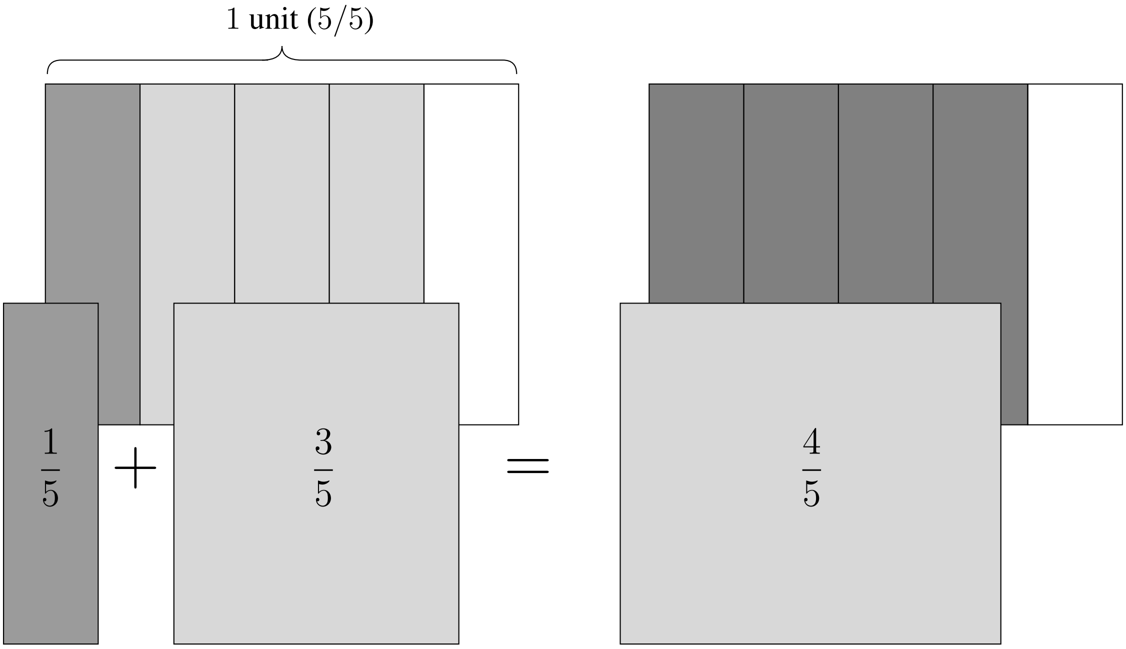
$$\begin{array}{rccccc} & {}^{+1}9 & 2^{+1} & 4 & 4 \\ + & 3 & 4 & 7 & 5 \\ \hline & 2 & 7 & 1 & 9 \end{array} \tag{5.3.46}$$

Finally:

$$\begin{array}{rcccccc} & & {}^{+1}9 & 2^{+1} & 4 & 4 \\ + & & 3 & 4 & 7 & 5 \\ \hline & 1 & 2 & 7 & 1 & 9 \end{array} \tag{5.3.47}$$

This example shows how we can proceed for the addition of any real numbers: we do an addition column by column from the right to the left and if the result of one addition is greater than 10, we report the left digit on the next (left) column.

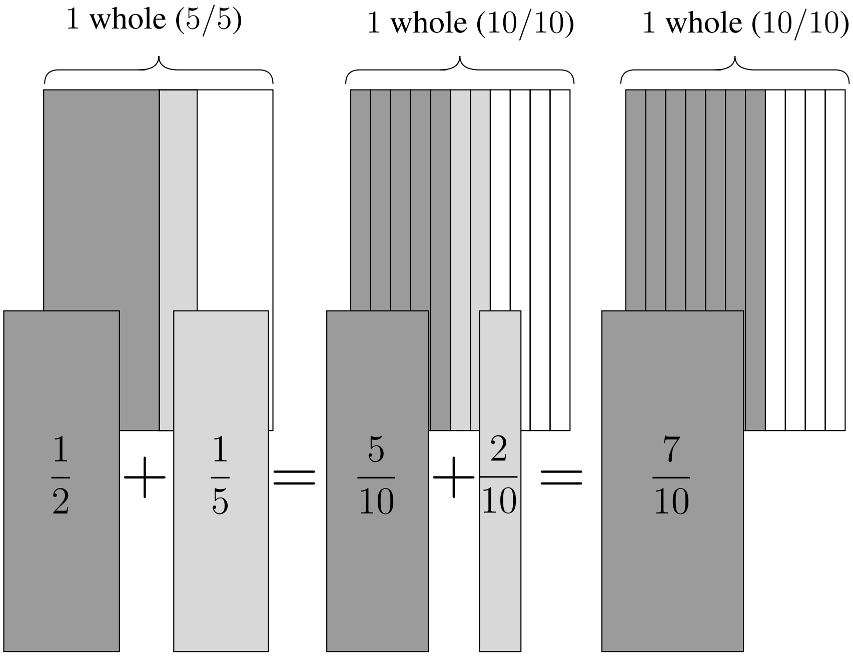
Following a reader request, here is also an illustrated example on how we teach to add simple fractions together at the middle school level, first in the case where the denominators are the same:



1 unit (5/5)
$\frac{1}{5}$
+
$\frac{3}{5}$
=
$\frac{4}{5}$

Figure 5.30: **Addition of fractions with common denominator**

Or if the denominators are not common, we seek common fractions equivalent to each term of the addition, in such a way that all the fractions have a common denominator and afterwards we add as we did before:



1 whole (5/5)
1 whole (10/10)
1 whole (10/10)
$\frac{1}{2}$
+
$\frac{1}{5}$
=
$\frac{5}{10}$
+
$\frac{2}{10}$
=
$\frac{7}{10}$

Figure 5.31: **Addition of fractions without common denominators**

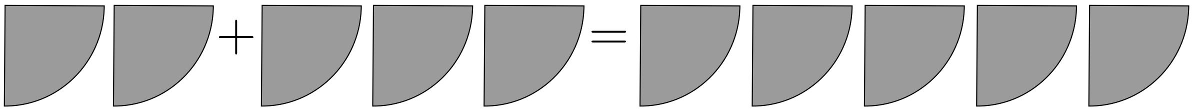
We then see above that to add a fraction from another we first put the fraction at the same denominator, we then add the numerators and we keep the denominator if there is no possible simplification:

$$\frac{1}{2}+\frac{1}{5}=\frac{5}{5}\cdot\frac{1}{2}-\frac{2}{2}\cdot\frac{1}{4}=\frac{5}{10}+\frac{2}{10}=\frac{7}{10} \tag{5.3.48}$$

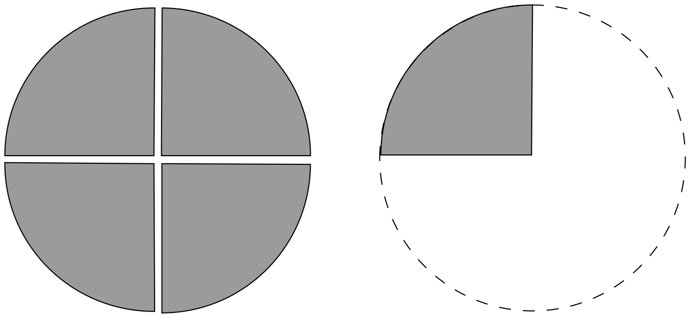
Obviously when we add fractions together we could also get a number that represents another number that is greater than 1 as for example:

$$\frac{2}{4}+\frac{3}{4}=\frac{5}{4}=1.25 \tag{5.3.49}$$

This can be illustrated as following:



If you want to assemble these quarter discs, here is what we get:



You understand then why we can say that we have $5/4$ of a disc!

This algorithm (process or methodology) of addition is quite simple to understand and to execute. We will not go further on this subject at this day!

Below a typical addition table for the first twelve natural numbers:

+	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**
1	2	3	4	5	6	7	8	9	10	11	12	13
2	3	4	5	6	7	8	9	10	11	12	13	14
3	4	5	6	7	8	9	10	11	12	13	14	15
4	5	6	7	8	9	10	11	12	13	14	15	16
5	6	7	8	9	10	11	12	13	14	15	16	17
6	7	8	9	10	11	12	13	14	15	16	17	18
7	8	9	10	11	12	13	14	15	16	17	18	19
8	9	10	11	12	13	14	15	16	17	18	19	20
9	10	11	12	13	14	15	16	17	18	19	20	21
10	11	12	13	14	15	16	17	18	19	20	21	22
11	12	13	14	15	16	17	18	19	20	21	22	23
12	13	14	15	16	17	18	19	20	21	22	23	24

Figure 5.32: **Addition table of the first 12 natural numbers**

5.3.2.2 Subtraction

Definition (#5.3.57): The "subtraction" is a mathematical operation that represents the operation of removing objects from a collection. More formally the subtraction of the number A by the number B denoted by the symbol "$-$" consist in founding the number C such that added to B gives A.

Remark

As we saw it in the section of Set Theory (page 404) the subtraction in the set $\mathbb{N}$ could be possible only if $A > B$.

Formally we write an inline literal subtraction in the form:

$$A - B = C \tag{5.3.50}$$

That must satisfies:

$$A = B + C \tag{5.3.51}$$

Or in schematic form of a special case:

$$10 - 3 - 4 = 7 - 4 = 3$$

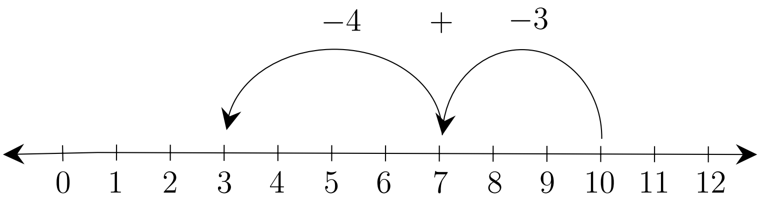


Figure 5.33: One possible schema for subtraction

Here are some intuitive properties that we assume without proof for the subtraction operation (as it can be deduce from the addition...):

P1. The subtraction of several numbers depends on the order of the terms. We say when than subtraction is a "non-commutative operation". Indeed:

$$5 - 2 \neq 2 - 5 \tag{5.3.52}$$

P2. The subtraction of several numbers change if we replace two or more of them by their intermediate result. We say when the subtraction is a "non-associative operation". Indeed:

$$5 - (3 - 2) \neq (5 - 3) - 2 \tag{5.3.53}$$

P3. The zero is not the neutral element of subtraction. Indeed, any number to which we subtract zero gives the same number, so zero is neutral on the right ... but not left because any number we subtract to zero does not give zero! We then say that the zero is only "neutral on the right" in the case of subtraction. Indeed:

$$0 - 5 \neq 0 \tag{5.3.54}$$

P4. Depending on the set in which we work, the subtraction can include a term in such a way that the total is zero. We then say that there is a "opposite" for the subtraction.

In most complicated cases we have a special vocabulary:

$$\begin{array}{rrrl} -1 & & & \longleftarrow \text{carry} \\ 7 & 0 & 4 & \longleftarrow \text{Minuend} \\ 5 & 1 & 2 & \longleftarrow \text{Subtrahend} \\ \cline{1-3} 1 & 9 & 2 & \longleftarrow \text{Rest or Difference} \end{array} \tag{5.3.55}$$

The "minuend" is 704, the "subtrahend" is 512. The minuend digits are $m_3 = 7$, $m_2 = 0$ and $m_1 = 4$. The subtrahend digits are $s_3 = 5$, $s_2 = 1$ and $s_1 = 2$. Beginning at the one's place, 4 is not less than 2 so the difference 2 is written down in the result's one place. In the ten's place, 0 is less than 1, so the 0 is increased by 10, and the difference with 1, which is 9, is written down in the ten's place. The American method corrects for the increase of ten by reducing the digit in the minuend's hundreds place by one. That is, the 7 is struck through and replaced by a 6. The subtraction then proceeds in the hundreds place, where 6 is not less than 5, so the difference is written down in the result's hundred's place. We are now done, the result is 192.

Let us see now some concrete examples of subtractions of various simple number in the purpose to practice the basis:

✍**Example:**

The subtraction of two relatively small numbers is pretty easy once we memorized to count to at least the number resulting from this operation. So:

$$\begin{array}{rr} & 5 \\ - & 2 \\ \hline & 3 \end{array} \tag{5.3.56}$$

and:

$$\begin{array}{rr} & 10 \\ - & 3 \\ \hline & 7 \end{array} \tag{5.3.57}$$

and:

$$\begin{array}{rr} & 1014 \\ - & 3 \\ \hline & 1011 \end{array} \tag{5.3.58}$$

For larger numbers another possible method must be learned by heart (as well as for the addition). For example:

$$\begin{array}{rr} & 4574 \\ - & 3785 \\ \hline & ? \end{array} \tag{5.3.59}$$

we subtract the columns (4 columns in this example) from right to left. In the first column we have $4-5=-1<0$ so we report -1 to the next column (second one) and we write $10-1=9$ below the horizontal line of the first column:

$$\begin{array}{rrrrr} & 4 & 5 & 7^{-1} & 4 \\ - & 3 & 7 & 8 & 5 \\ \hline & & & & 9 \end{array} \tag{5.3.60}$$

and we continue as well for the second column $7-8=-1<0$ so that we report -1 on the next column (third one) and as $-1-1=-2$ we report $10-2=8$ below the horizontal bar of the second column:

$$\begin{array}{rrrrr} & 4 & 5^{-1} & 7^{-1} & 4 \\ - & 3 & 7 & 8 & 5 \\ \hline & & & 8 & 9 \end{array} \tag{5.3.61}$$

The third column is calculated as $5-7=-2<0$ and we report -1 on the next column (fourth one) and as $-1-2=-3$ we report $10-3=7$ below the line of the third column bar:

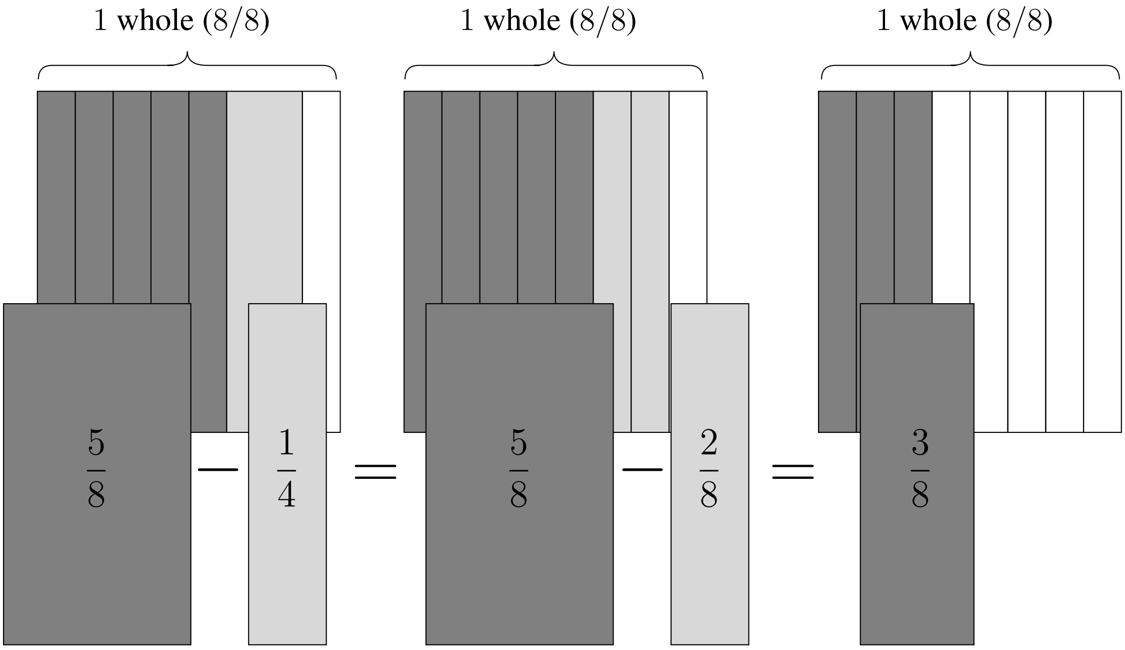
$$\begin{array}{rrrrr} & 4^{-1} & 5^{-1} & 7^{-1} & 4 \\ - & 3 & 7 & 8 & 5 \\ \hline & & 7 & 8 & 9 \end{array} \tag{5.3.62}$$

In the last column we have $4-3=1>0$ therefore we report the nothing on the next column and as $1-1=0$ we report 0 below the line of the fourth column bar:

$$\begin{array}{rrrrr} & 4^{-1} & 5^{-1} & 7^{-1} & 4 \\ - & 3 & 7 & 8 & 5 \\ \hline & 0 & 7 & 8 & 9 \end{array} \tag{5.3.63}$$

That's how we therefore we proceed to subtracting any numbers. We make a subtraction by column from the right to the left and if the result is a subtraction is less than zero we report -1 to the next column and the addition of the latest report on the subtraction obtained below the line.

Following a reader request, here is also an illustrated example on how we teach to subtract simple fractions together at the middle school level:



1 whole (8/8)
1 whole (8/8)
1 whole (8/8)
$\frac{5}{8}-\frac{1}{4}=\frac{5}{8}-\frac{2}{8}=\frac{3}{8}$

Figure 5.34: **Subtraction of fractions without common denominators**

We then see above that to subtract a fraction from another we first put the fraction at the same denominator, we then subtract the numerators and we keep the denominator if there is no possible simplification:

$$\frac{5}{8}-\frac{1}{4}=\frac{5}{8}-\frac{2}{2}\cdot\frac{1}{4}=\frac{5}{8}-\frac{2}{8}=\frac{3}{8} \tag{5.3.64}$$

We have when we mix the addition and subtraction the following resulting relation that should be obvious for most readers:

$$\begin{aligned} a+(b-c)&=(a+b)-c\\ a-(b+c)&=(a-b)-c\\ a-(b-c)&=(a-b)+c\\ a-b&=(a-c)-(b-c) \end{aligned} \tag{5.3.65}$$

The methodology used for subtraction being based on exactly the same rules that for addition we will expand the subject more as this seems actually useless in our point of view. This method is very simple and of course requires some habits to work with numbers to be fully understood and mastered.

Below a typical subtraction table for the first twelve natural numbers:

−	1	2	3	4	5	6	7	8	9	10	11	12
1	0	1	2	3	4	5	6	7	8	9	10	11
2	−1	0	1	2	3	4	5	6	7	8	9	10
3	−2	−1	0	1	2	3	4	5	6	7	8	9
4	−3	−2	−1	0	1	2	3	4	5	6	7	8
5	−4	−3	−2	−1	0	1	2	3	4	5	6	7
6	−5	−4	−3	−2	−1	0	1	2	3	4	5	6
7	−6	−5	−4	−3	−2	−1	0	1	2	3	4	5
8	−7	−6	−5	−4	−3	−2	−1	0	1	2	3	4
9	−8	−7	−6	−5	−4	−3	−2	−1	0	1	2	3
10	−9	−8	−7	−6	−5	−4	−3	−2	−1	0	1	2
11	−10	−9	−8	−7	−6	−5	−4	−3	−2	−1	0	1
12	−11	−10	−9	−8	−7	−6	−5	−4	−3	−2	−1	0

Figure 5.35: **Subtraction table of the first 12 natural numbers**

Remark

Addition seems to be a simple operation however in some well known book simple kindergarten level sums are wrong. Like for example in the King James Version of Bible (one of the many different existing translated version of the Bible existing around the World), Ezra 1:9-10 (old testament). The inventory of the sum leads to a wrong total ($5,469$ instead of $2,499$):

Verse Number	Description	Quantity
`I-9`	gold dishes	30
	silver dishes	1,000
	knives	29
`I-10`	basons of gold	30
	silver basons of a second sort	410
	other vessels	1,000
`I-11`	Total	5,469

Some high level reputed professional theologians tried to find a workaround to explain this error in a "godly" book but failed (see [487]). And such an error occurs multiple times in the Bible not only once!

5.3.2.3 Multiplication

Definition (#5.3.58): The "multiplication" of numbers is an operation that has for purpose, given two numbers, one named "multiplier" m, and the other "multiplicand" M, to find a third number named "product" P that is the sum (multiplication is only a successive number of sums!) as many equal numbers to the multiplicand as there are units multiplier:

$$m \times M = \underset{(1)}{M} + \underset{(2)}{M} + \underset{(3)}{M} + \ldots + \underset{(m)}{M} = \sum_{i=1}^{m} M = P \qquad (5.3.66)$$

The multiplicand and multiplier are named "product factors".

The multiplication is indicated in kindergarten by the symbol "$\times$"of the elevated dot symbol in higher classes "$\cdot$" or even when there is no possible confusion... without anything:

$$\boxed{a \times b = a \cdot b = ab} \qquad (5.3.67)$$

We can define the multiplication using the Peano axioms in the special case of natural numbers $\mathbb{N}$ as already mentioned in the section Numbers (page 218). Thus, with these axioms it is possible to prove that there is (exists) one and only one (unique) application, denoted "$\times$" or more often "$\cdot$" of $\mathbb{N}^2$ to $\mathbb{N}$ satisfying:

$$\begin{aligned} &\forall n \in \mathbb{N}: & n \cdot 0 &= 0 \\ &\forall p \in \mathbb{N}, \forall q \in \mathbb{N}: & p(q+1) &= pq + q \end{aligned} \qquad (5.3.68)$$

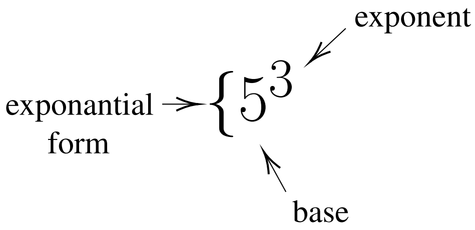
Remark

As this textbook has not be written for mathematicians, we will pass the proof (relatively long and of little interest in the case of business) and we will assume that the application "$\times$" exists and is unique ... and that it follows from the above properties.

The "power" is a specific notation of a special case of the multiplication. When to multiplicand(s) and the multiplier(s) are typically identical in numerical values, we denote therefore the multiplication by (for example):

$$n \cdot n \cdot n \cdot n \cdot n \cdot n \cdot n \cdot n = n^8 \qquad (5.3.69)$$

This is what we name the "power notation" or "exponentiations". The number in superscript is what we the name the "power" or the "exponent" of the number. The notation with exponents is said to be seen for the first time in a book of Chuquet in 11484 (holocene calendar).



In general:

$$\underbrace{n \cdot n \cdot n \cdot \ldots \cdot n \cdot n \cdot n \cdot n}_{m \text{ times}} = n^m \qquad (5.3.70)$$

You can check by yourself that its properties are the following (for example):

$$n^x n^y = n^{x+y} \tag{5.3.71}$$

and also:

$$a^x b^x = (ab)^x \tag{5.3.72}$$

Here are some obvious properties about the multiplication that we will admit without proof (this is a Set properties point of view listing):

P1. The multiplication of several numbers does not depend on the order of terms. Then we say that multiplication is a "commutative operation".

P2. The multiplication of several numbers does not change if we replace two or more of them by their intermediate result. We then say that the multiplication is an "associative operation".

P3. The unit is the neutral element of the multiplication as any multiplicand multiplied by the multiplier 1 is equal to the multiplicand itself.

P4. The multiplication may have a term such that the product is equal to unity (the neutral element). Then we say that there exists a "multiplicative inverse" (but this depends strictly speaking in what set of numbers we work as in some the concept of decimal number does not exist!).

P5. Multiplication is a "distributive operation", that is to say:

$$a \cdot (b + c) = ab + ac \tag{5.3.73}$$

the reverse being named a "factorization operation".

✍**Example:**

Probably the best-known case in the world of factorization (by users of spreadsheets softwares like Microsoft® Excel®) is the calculation of the addition or removal of a tax on a given amount! For example, consider adding 8% VAT to an amount of 100.-. This will typically be written in one of the following ways:

$$100+100\cdot8\% = 100\cdot1+100\cdot8\% = 100\cdot(1+8\%) = 100\cdot(1+8/100) = 100\cdot1.08$$

P6. Any number at the power of zero is equal to 1 as:

$$n^0 = n^m n^{-m} = \frac{n^m}{n^m} = 1 \tag{5.3.74}$$

From this result some deduce too quickly (and even some professors teach it!) that $0^0 = 1$. But in reality 0^0 is just undefined as it the ratio of two zeros.

Remark

There are two main reasons why some professors teach $0^0 = 1$. The first one is an application of the binomial theorem (see section Calculus page 1364):

$$(1+x)^n = \sum_{k=0}^{n} \begin{pmatrix} n \\ k \end{pmatrix} 1^{n-k} x^k$$

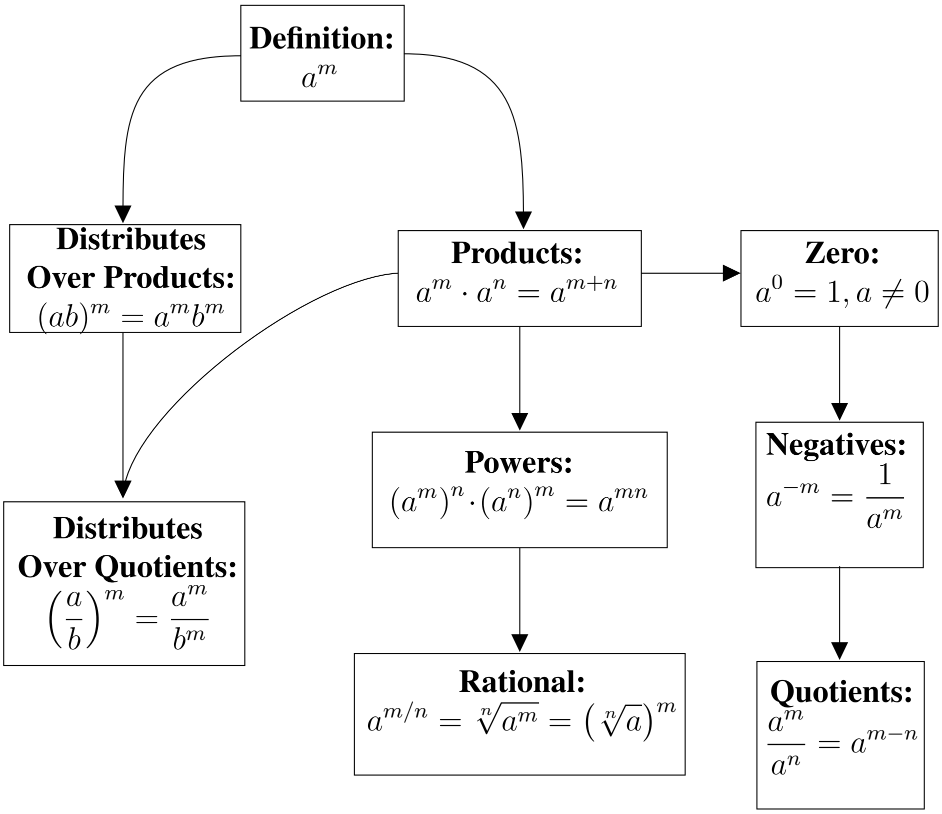
When $x = 0$, the expression becomes:

$$\begin{aligned}(1+0)^n &= \sum_{k=0}^{n} \begin{pmatrix} n \\ k \end{pmatrix} 1^{n-k} 0^k \\ 1^n &= 1 \cdot 0^0 \\ 1 &= 1 \cdot 0^0\end{aligned}$$

In this context, 0^0 has to be equal to 1.

The second go with the reasoning that 1^1 is 1, $0.5^{0.5}$ is 0.70 etc. x^x goes down from one until it hits 0.4 and then it goes back up and approaches the limit of one but never hits. I.e. $0.000000001^{0.000000001}$ is almost 1, so some people round 0^0 to 1.

To summarize it seems that there are no international convention as far as we know.



Definition: a^m
Distributes Over Products: $(ab)^m = a^m b^m$
Products: $a^m \cdot a^n = a^{m+n}$
Zero: $a^0 = 1, a \neq 0$
Distributes Over Quotients: $\left(\frac{a}{b}\right)^m = \frac{a^m}{b^m}$
Powers: $(a^m)^n \cdot (a^n)^m = a^{mn}$
Negatives: $a^{-m} = \frac{1}{a^m}$
Rational: $a^{m/n} = \sqrt[n]{a^m} = \left(\sqrt[n]{a}\right)^m$
Quotients: $\frac{a^m}{a^n} = a^{m-n}$

Figure 5.36: **Summary of exponents rules**

Let us also introduce some special notations for the multiplication:

1. Given any numbers $x_1, x_2, \ldots, x_n$ (not necessarily equal) then we can write the product as following:

$$\boxed{x_1 \cdot x_2 \cdot \ldots \cdot x_n = \prod_{i=1}^{n} x_i} \tag{5.3.75}$$

   by defining upper and lower bounds to the indexed product (above and below the uppercase Greek letter "Pi").

   We trivially have respectively to the latter notation (on request we can detail more...):

$$\prod_{i=1}^{n} kx_i = k^n \prod_{i=1}^{n} x_i \tag{5.3.76}$$

   for any number k such that:

$$\prod_{i=1}^{n} k = k^n \tag{5.3.77}$$

   We also have for example:

$$\prod_{i=1}^{n} (x+y) = (x+y)^n \tag{5.3.78}$$

2. We define the "factorial" simply ("simply"... because it exists also a more complex way of defining it through the Euler Gamma function as it is done in the section of Integral and Differential Calculus page 1574) by:

$$\boxed{1 \times 2 \times 3 \times 4 \times \cdots \times n = n!} \tag{5.3.79}$$

   with the special fact that (only the complex definition mentioned before can make this fact obvious... so for the proof see again page 1577):

$$0! = 1 \tag{5.3.80}$$

Let us see some simple examples of basic multiplications:

✍**Examples:**

E1. The multiplication of two relatively small numbers is fairly easy once we have memorized count to at least the number resulting from this operation. So:

$$\begin{array}{rr} & 5 \\ \times & 2 \\ \hline & 10 \end{array} \qquad \begin{array}{rr} & 10 \\ \times & 3 \\ \hline & 30 \end{array} \qquad \begin{array}{rr} & 1014 \\ \times & 3 \\ \hline & 3042 \end{array} \tag{5.3.81}$$

E2. For much larger numbers we must adopt another method that has to be memorized.

For example:

$$\begin{array}{r} 4\,5\,7\,4 \\ \times \qquad 8 \\ \hline 3\,2 \\ 5\,6 \\ 4\,0 \\ 3\,2 \end{array} \tag{5.3.82}$$

This methodology is very logical if you understand how we build a number in base ten. Thus we have (we'll assume that the distributive property is mastered):

$$\begin{aligned} 8\times 4574 &= 8\times(4\cdot 10^3+5\cdot 10^2+7\cdot 10^1+4\cdot 10^0)\\ &= 8\times 4000+8\times 500+8\times 70+8\times 4\\ &= 32\cdot 10^3+40\cdot 10^2+56\cdot 10^1+32\cdot 10^0\\ &= 36592 \end{aligned} \tag{5.3.83}$$

To avoid overloading the notations in the multiplication by the "vertical" method, we do not represent the zeros that would overload unnecessarily the calculations (and even more if the multiplier and / or the multiplicand are very large numbers).

Following a reader request, here is also an illustrated example on how we teach (on possible way among others) to multiply simple fractions together at the middle school level:

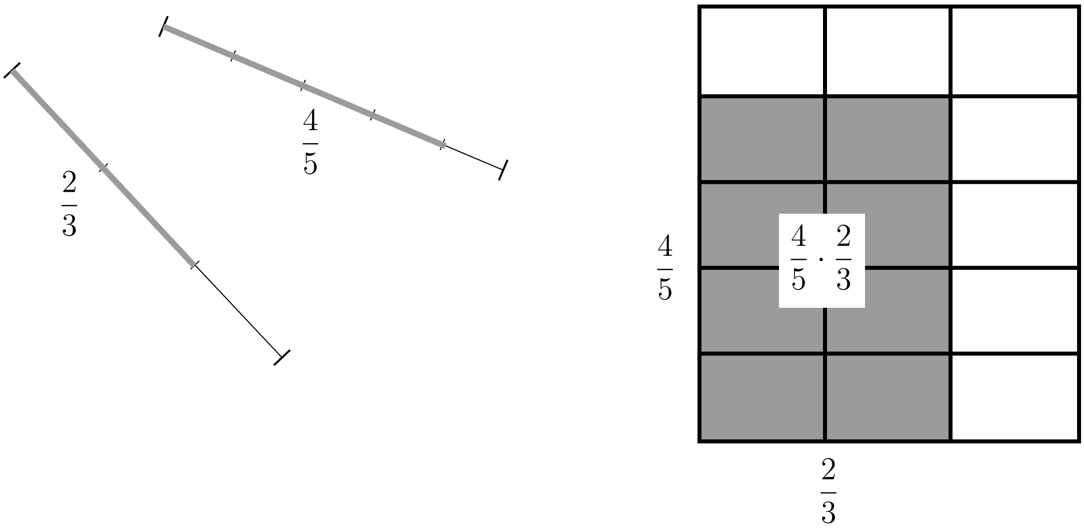


Figure 5.37: **Multiplication of fractions without common denominators**

We have therefore:

$$\frac{2}{3}\cdot\frac{4}{5}=\frac{8}{15} \tag{5.3.84}$$

This example illustrates that to multiply two fractions we simply multiply the numerators together and the denominators together.

Below a typical multiplication table for the first twelve natural numbers:

×	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**
1	1	2	3	4	5	6	7	8	9	10	11	12
2	2	4	6	8	10	12	14	16	18	20	22	24
3	3	6	9	12	15	18	21	24	27	30	33	36
4	4	8	12	16	20	24	28	32	36	40	44	48
5	5	10	15	20	25	30	35	40	45	50	55	60
6	6	12	18	24	30	36	42	48	54	60	66	72
7	7	14	21	28	35	42	49	56	63	70	77	84
8	8	16	24	32	40	48	56	64	72	80	88	96
9	9	18	27	36	45	54	63	72	81	90	99	108
10	10	20	30	40	50	60	70	80	90	100	110	120
11	11	22	33	44	55	66	77	88	99	110	121	132
12	12	24	36	48	60	72	84	96	108	120	132	144

Figure 5.38: **Multiplication table of the first 12 natural numbers**

Caution!! Multiplication can't be applied universally in life or science, especially when dimensions are involved and that is related to what we name "dimensional analysis" that has for purpose to check the consistency of mathematical operations applied to real-life cases. Multiplication (and derived operations) is valid only when the resulting quantity makes physical sense therefore multiplying 0 cow by 5 cows doesn't make sense and is a calculation that must not be done as the dimensional result are cows squared, i.e. $[\text{cow}^2]$. Dimensional analysis is like a grammar for the language of physics. Just as you wouldn't mix verbs and nouns randomly in a sentence, you can't mix units and dimensions arbitrarily in equations. Multiplication is powerful—but only when it respects the structure of the physical world.

5.3.2.4 Division

Definition (#5.3.59): The "division" of integers (to start with the simplest case ...) is an operation, which aims, given two integers, one named "dividend" D, the other named "divider" d , to find a third number named "quotient" Q which is the largest number whose product by the divisor can be subtracted (so the division result of the subtraction!) the dividend (the difference being named the "rest" R or sometimes the "congruence").

Remark

In the case of real numbers there are never any rest at the end of the division operation (because the quotient multiplied by the divisor gives always exactly the dividend)!

Generally in the context of integers (or algebraic equation division), if we denote by D the dividend and by d the divisor, the quotient Q and the remainder R we have the relation:

$$\boxed{D = Q \cdot d + R} \tag{5.3.85}$$

knowing that the division was initially written as follows:

$$D : d = \frac{D}{d} \tag{5.3.86}$$

We indicate the operation of division by placing between the two numbers, the dividend and the divider, a symbol ":" or a slash "/" or even in kindergarten with the symbol $\div$.

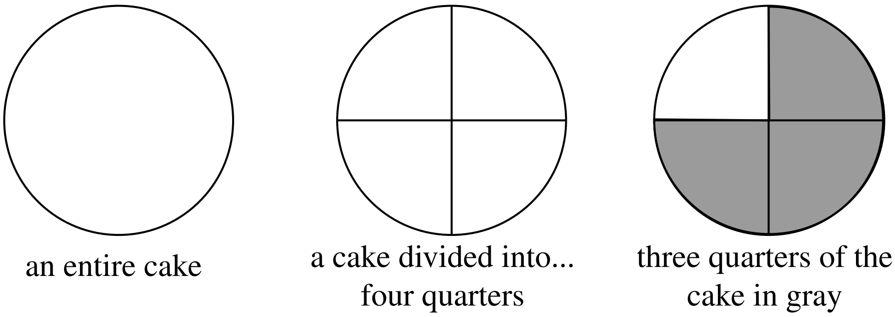
We refer also often by the term "fraction" (instead of "quotient"), the ratio of two numbers or in other words, the division of the first by the second.

Remark

The sign of division ":" is said to be due to Gottfried Wilhelm Leibniz. The slash symbol could have been see for the first time in the works of Leonardo Fibonacci (11202) and is probably due to the Hindus.

If we divide two numbers and we want an integer as quotient and as remainder (if there is one...), then we speak of "Euclidiean division".

For example, dividing a cake, is not a Euclidean division because the quotient is not an integer, except if one takes the four quarters...:

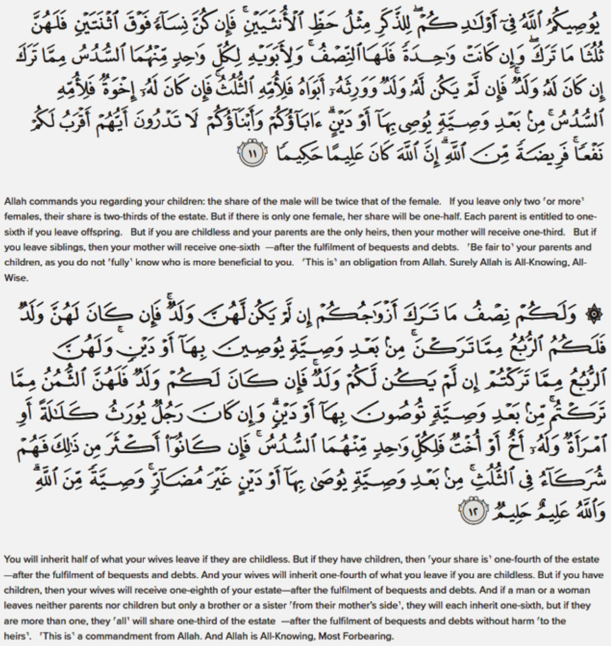


an entire cake
a cake divided into... four quarters
three quarters of the cake in gray

Figure 5.39: Schematic example of a division (fractions)

Remark

Fractions can seem easy to handle. However this is not the easy for everyone. Like in the Quran for example they tried to do a general rule of inheritance that fail in some cases and that's quite a shame for a "godly" book with rules provided by an omniscient entity... Let's see that with the Surah An-Nisa 4:11-12 from the Warsh Quran (one of the many arabic different existing Qurans around the World):



يُوصِيكُمُ ٱللَّهُ فِيٓ أَوۡلَٰدِكُمۡۖ لِلذَّكَرِ مِثۡلُ حَظِّ ٱلۡأُنثَيَيۡنِۚ فَإِن كُنَّ نِسَآءٗ فَوۡقَ ٱثۡنَتَيۡنِ فَلَهُنَّ
ثُلُثَا مَا تَرَكَۖ وَإِن كَانَتۡ وَٰحِدَةٗ فَلَهَا ٱلنِّصۡفُۚ وَلِأَبَوَيۡهِ لِكُلِّ وَٰحِدٖ مِّنۡهُمَا ٱلسُّدُسُ مِمَّا تَرَكَ
إِن كَانَ لَهُۥ وَلَدٞۚ فَإِن لَّمۡ يَكُن لَّهُۥ وَلَدٞ وَوَرِثَهُۥٓ أَبَوَاهُ فَلِأُمِّهِ ٱلثُّلُثُۚ فَإِن كَانَ لَهُۥٓ إِخۡوَةٞ فَلِأُمِّهِ
ٱلسُّدُسُۚ مِنۢ بَعۡدِ وَصِيَّةٖ يُوصِي بِهَآ أَوۡ دَيۡنٍۗ ءَابَآؤُكُمۡ وَأَبۡنَآؤُكُمۡ لَا تَدۡرُونَ أَيُّهُمۡ أَقۡرَبُ لَكُمۡ
نَفۡعٗاۚ فَرِيضَةٗ مِّنَ ٱللَّهِۗ إِنَّ ٱللَّهَ كَانَ عَلِيمًا حَكِيمٗا ١١

Allah commands you regarding your children: the share of the male will be twice that of the female. If you leave only two 'or more' females, their share is two-thirds of the estate. But if there is only one female, her share will be one-half. Each parent is entitled to one-sixth if you leave offspring. But if you are childless and your parents are the only heirs, then your mother will receive one-third. But if you leave siblings, then your mother will receive one-sixth —after the fulfilment of bequests and debts. 'Be fair to' your parents and children, as you do not 'fully' know who is more beneficial to you. 'This is' an obligation from Allah. Surely Allah is All-Knowing, All-Wise.

۞ وَلَكُمۡ نِصۡفُ مَا تَرَكَ أَزۡوَٰجُكُمۡ إِن لَّمۡ يَكُن لَّهُنَّ وَلَدٞۚ فَإِن كَانَ لَهُنَّ وَلَدٞ
فَلَكُمُ ٱلرُّبُعُ مِمَّا تَرَكۡنَۚ مِنۢ بَعۡدِ وَصِيَّةٖ يُوصِينَ بِهَآ أَوۡ دَيۡنٖۚ وَلَهُنَّ
ٱلرُّبُعُ مِمَّا تَرَكۡتُمۡ إِن لَّمۡ يَكُن لَّكُمۡ وَلَدٞۚ فَإِن كَانَ لَكُمۡ وَلَدٞ فَلَهُنَّ ٱلثُّمُنُ مِمَّا
تَرَكۡتُمۚ مِّنۢ بَعۡدِ وَصِيَّةٖ تُوصُونَ بِهَآ أَوۡ دَيۡنٖۗ وَإِن كَانَ رَجُلٞ يُورَثُ كَلَٰلَةً أَوِ
ٱمۡرَأَةٞ وَلَهُۥٓ أَخٌ أَوۡ أُخۡتٞ فَلِكُلِّ وَٰحِدٖ مِّنۡهُمَا ٱلسُّدُسُۚ فَإِن كَانُوٓاْ أَكۡثَرَ مِن ذَٰلِكَ فَهُمۡ
شُرَكَآءُ فِي ٱلثُّلُثِۚ مِنۢ بَعۡدِ وَصِيَّةٖ يُوصَىٰ بِهَآ أَوۡ دَيۡنٍ غَيۡرَ مُضَآرّٖۚ وَصِيَّةٗ مِّنَ ٱللَّهِۗ
وَٱللَّهُ عَلِيمٌ حَلِيمٞ ١٢

You will inherit half of what your wives leave if they are childless. But if they have children, then 'your share is' one-fourth of the estate —after the fulfilment of bequests and debts. And your wives will inherit one-fourth of what you leave if you are childless. But if you have children, then your wives will receive one-eighth of your estate—after the fulfilment of bequests and debts. And if a man or a woman leaves neither parents nor children but only a brother or a sister 'from their mother's side', they will each inherit one-sixth, but if they are more than one, they 'all' will share one-third of the estate —after the fulfilment of bequests and debts without harm 'to the heirs'. 'This is' a commandment from Allah. And Allah is All-Knowing, Most Forbearing.

Let's imagine the particular but simple case that we are a man, who has 1 wife, 2 daughters, a father and a mother. We have no sisters or brothers. Unfortunately consider that we died in a car accident and left $1,000$ USD as an inheritance. So let's apply the above rules:

1. According to verse `4:12`, our wife will receive $1/8$ of our $1,000$ USD. Hence: $(1/8)\cdot 1,000 = 125$ USD.
2. According to verse `4:11`, our 2 daughters will receive $2/3$. Hence: $(2/3)\cdot 1000 = 666.\bar{6}$ USD.
3. According to verse `4:11`, our father will receive $1/6$. Hence: $(1/6)\cdot 1000 = 166.\bar{6}$ USD.
4. According to verse `4:11`, our mother will receive $1/6$. Hence: $(1/6)\cdot 1000 = 166.\bar{6}$ USD.

Hence a total of:

$$\left(\frac{1}{8}+\frac{2}{3}+\frac{1}{6}+\frac{1}{6}\right)\cdot 1000 = 125 + 666.\bar{6} + 166.\bar{6} + 166.\bar{6} = \frac{27}{24}\cdot 1000 = 1125$$

So a fraction of $27/24 > 1$ of the initial amount (money was created from nothing...). Huge failure... !

If we have:

$$D : d = D\cdot\frac{1}{d} = D\cdot i_D \qquad (5.3.87)$$

we denote by i_D the inverse of the dividend. At any number is associated an inverse that satisfies this condition. From this definition it comes the notation (with x being any number other than zero)

$$\frac{x}{x}=x^1\cdot x^{-1}=x^{1-1}=x^0=1 \tag{5.3.88}$$

In the case of two fractional numbers, we say they are "inverse" or "reciprocal", when their product is equal to unity (as the previous relations).

Remarks

R1. A division by zero is what we name a "singularity". That is to say the result of the division is: undetermined!!

R2. When we multiply the dividend and the divisor of a division (fraction) by a same number, the quotient does not change (this is an: "equivalent fraction"), but the remainder is multiplied by that number.

R3. Divide a number by a product made of several factors is equivalent to divide this number successively by each of the factors of the product and vice versa.

R4. Fractions that are greater than 0 but less than 1 are named "proper fractions". In proper fractions, the numerator is less than the denominator. When a fraction has a numerator that is greater than or equal to the denominator, the fraction is an "improper fraction". An improper fraction is always 1 or greater than 1. And, finally, a mixed number is a combination of a whole number and a proper fraction.

The properties of the divisions with the condensed power notations (exponentiation) are typically as example (we will leave to the reader the fact to check this up to with numerical values):

$$\frac{x\cdot x\cdot x}{y\cdot y}=x^3\cdot y^{-2} \tag{5.3.89}$$

or obviously another example:

$$\frac{x\cdot x\cdot x}{x\cdot x}=\frac{x}{x}\cdot\frac{x}{x}\cdot x=1\cdot 1\cdot x=x^3\cdot x^{-2}=x^1=x \tag{5.3.90}$$

We therefore deduce that:

$$\frac{x^p}{x^q}=x^{p-q} \tag{5.3.91}$$

Let us recall that a prime number (relative integer $\mathbb{Z}$) is a number greater than 1 that has for divisors only itself and unity (remember that 2 is prime for example). Therefore any number that is not prime has at least one prime number as a divisor (except 1 by definition!). The smallest divisors of an integer is a prime number (we will detail the properties of prime numbers relatively to the operation of division in the section Numbers Theory page 220).

Let us see some properties of the division (some of us are already known because they arise from logical reasoning of the multiplication properties):

$$\begin{aligned}
&\frac{a}{b}=\frac{c}{d}\Leftrightarrow a\cdot d=b\cdot c && \frac{a\cdot d}{b\cdot d}=\frac{a}{b}\cdot\frac{d}{d}=\frac{a}{b}\cdot 1=\frac{a}{b}\\
&\frac{a}{-b}=\frac{-a}{b}=-\frac{a}{b} && \frac{a}{b}+\frac{c}{b}=\frac{a+c}{b}\\
&\frac{a}{b}+\frac{c}{d}=\frac{a\cdot d+b\cdot c}{b\cdot d} && \frac{a}{b}\cdot\frac{c}{d}=\frac{a\cdot c}{b\cdot d}\\
&\frac{a}{b}\div\frac{c}{d}=\frac{a}{b}\cdot\frac{d}{c}=\frac{a\cdot d}{b\cdot c} && \frac{a}{b}b=a
\end{aligned}\tag{5.3.92}$$

where:

$$\frac{a}{b}=\frac{c}{d}\Leftrightarrow ad=bc\tag{5.3.93}$$

is what we name a "terms amplification" and:

$$\frac{a}{b}+\frac{c}{b}=\frac{a+c}{b}\tag{5.3.94}$$

is an operation consisting by putting everything with a "common denominator".

We also have the following properties:

P1. The division of several numbers depend on the order of terms. We then say that the division is a "non-commutative operation". This means we have when a that is different from b and that both are different from zero:

$$\frac{a}{b}\neq\frac{b}{a}\tag{5.3.95}$$

P2. The result of the division of several numbers change if we replace two or more of them by their intermediate result. We then say that the division is a "non-associative operation":

$$\frac{\left(\dfrac{a}{b}\right)}{c}\neq\frac{a}{\left(\dfrac{b}{c}\right)}\tag{5.3.96}$$

P3. The unit is the neutral element has that we multiply the dividend or the divider by 1 the result of the division remains the same:

$$\frac{a}{b}=\frac{1\cdot a}{b}=\frac{a}{1\cdot b}=1\cdot\frac{a}{b}\tag{5.3.97}$$

P4. The division may include a divider in such a way that the division is equal to unity (neutral element 1). We then say that there exist a "symmetrical to the division" that is obviously equal to the numerator (dividend) itself.

P5. The incrementation of numerator and denominator by a constant value is not equal to the initial ratio in the general case where $a\neq b$:

$$\frac{a}{b}\neq\frac{a+c^{te}}{b+c^{te}}\tag{5.3.98}$$

Now that we know the multiplication (and therefore power notation) and division, if we consider a and b are two positive real numbers, different from zero we have:

$$a^pa^q=\underbrace{a\cdot a\ldots\cdot a}_{p\text{-times}}\cdot\underbrace{a\cdot a\ldots\cdot a}_{q\text{-times}}=a^{p+q} \tag{5.3.99}$$

and (named sometimes the "zero exponent rule of exponents"):

$$\frac{a^p}{a^q}=\frac{\underbrace{a\cdot a\ldots\cdot a}_{p\text{-times}}}{\underbrace{a\cdot a\ldots\cdot a}_{q\text{-times}}}=\underbrace{a\cdot a\ldots\cdot a}_{p-q\text{-times}}=a^{p-q}\Rightarrow a^{-q}=\frac{1}{a^q} \tag{5.3.100}$$

and:

$$a^p\cdot b^p=(a\cdot b)^p\Leftrightarrow\frac{a^p}{b^p}=\left(\frac{a}{b}\right)^p \tag{5.3.101}$$

We have also obviously:

$$\frac{a^n}{a^n}=\frac{\underbrace{a\cdot a\ldots\cdot a}_{n\text{-times}}}{\underbrace{a\cdot a\ldots\cdot a}_{n\text{-times}}}=\underbrace{a\cdot a\ldots\cdot a}_{n-n\text{-times}}=a^0=1 \tag{5.3.102}$$

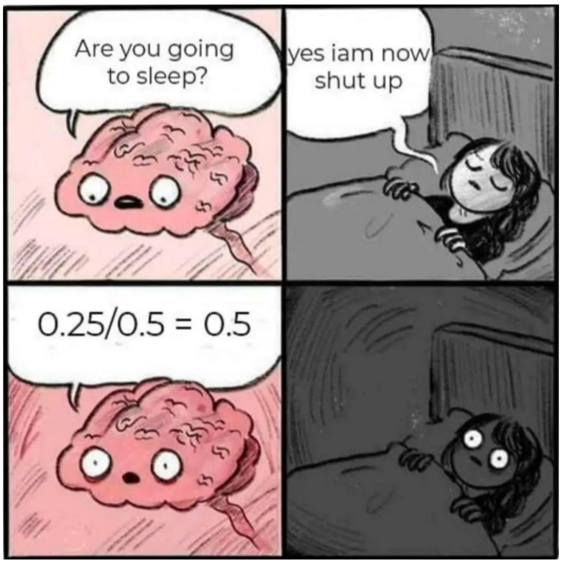
Therefore (not directly related to the subject of division... but shouldn't we introduce this now...?):

$$(a^n)^m=\underbrace{\underbrace{a\cdot a\ldots\cdot a}_{n\text{-times}}\cdot\ldots\underbrace{a\cdot a\ldots\cdot a}_{n\text{-times}}}_{m\text{ -times}}=\underbrace{a\cdot a\ldots\cdot a}_{mn\text{-times}}=a^{mn} \tag{5.3.103}$$

Remark

When dealing with division, be extremely careful abound dividing stuff by zero. This may lead to some absurd results, like the non-less famous one shared a lot on social networks:

$$\begin{aligned}a&=b\\a^2&=ab\\a^2-b^2&=ab-b^2\\(a+b)(a-b)&=b(a-b)\\a+b&=b\\2b&=b\\2&=1\end{aligned}$$



Are you going to sleep?
yes iam now shut up
0.25/0.5 = 0.5

5.3.2.5 n-root

Now that we have introduce in a simple and not too much formal way the operations of multiplication (and power notation) and division we can introduction the concept of n-root.

As we know for example that:

$$2^3 2^2 = 2^{3+2}$$

we can by reverse inference for example also write:

$$2^1 = 2^{0.5+0.5} = 2^{0.5} 2^{0.5} = 2^{1/2} 2^{1/2} \tag{5.3.104}$$

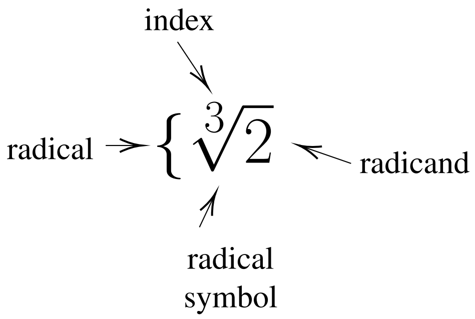
and therefore it means that fractional power exist! This is what we name n-root (in the above example we speak of 2-root).

We can now define the principal n-root of any number!

Definition (#5.3.60): In mathematics, the n-th root of a number a, where n is a positive integer, is a number r which, when raised to the power n yields x. That is to say such that: $r^n = x$, where n is the degree of the root. By convention we write:

$$\boxed{r = x^{1/n} := \sqrt[n]{x}} \tag{5.3.105}$$

Roots are usually written using the "radical" symbol $\sqrt[n]{\ldots}$ or also named the "radix". The number $n \in \mathbb{N}^*$ is named the "radicand" and sometimes the "index".



From what has been said for the powers, we can easily conclude that the n-th root of a product of several factors is the product of n-th roots of each factor:

$$\sqrt[n]{a} \cdot \sqrt[n]{b} = \sqrt[n]{a \cdot b} \Leftrightarrow \frac{\sqrt[n]{a}}{\sqrt[n]{b}} = \sqrt[n]{\frac{a}{b}} \tag{5.3.106}$$

as (seen previously):

$$(a^p)^q = a^{p \cdot q} = (a^q)^p \tag{5.3.107}$$

And therefore:

$$a^{\frac{p}{q}} = \sqrt[q]{a^p} = (\sqrt[q]{a})^p \quad \text{and} \quad \sqrt[p]{\sqrt[q]{a}} = \sqrt[pq]{a} \tag{5.3.108}$$

Obviously it comes:

$$\underbrace{\sqrt[n]{a} \cdot \sqrt[n]{a} \cdot \ldots \sqrt[n]{a}}_{n\text{-times}} = n \tag{5.3.109}$$

We also have if $a < 0$:

$$\sqrt[n]{a^n} = a \tag{5.3.110}$$

if $n \in \mathbb{N}^*$ is odd and:

$$\sqrt[n]{a^n} = |a| \tag{5.3.111}$$

if $n \in \mathbb{N}^*$ is even.

If $x < 0$ and $n \in \mathbb{N}^*$ is odd then:

$$y = a^{1/n} = \sqrt[n]{x} \tag{5.3.112}$$

is the number y such that:

$$b^n = x \tag{5.3.113}$$

If $n \in \mathbb{N}^*$ is even then obviously, as we already have seen it earlier, the root belong to $\mathbb{C}$ (see section Numbers page 243).

If the denominator of a fraction contains a factor of the form $\sqrt[n]{a^k}$ with $a \neq 0$, by multiplying the numerator and denominator by $\sqrt[n]{a^{n-}}$, we will remove the root of the denominator, since:

$$\frac{x}{\sqrt[n]{a^k}} \frac{\sqrt[n]{a^{n-k}}}{\sqrt[n]{a^{n-k}}} = \frac{x\sqrt[n]{a^{n-k}}}{\sqrt[n]{a^k}\sqrt[n]{a^{n-k}}} = \frac{x\sqrt[n]{a^{n-k}}}{\sqrt[n]{a^k a^{n-k}}} = \frac{x\sqrt[n]{a^{n-k}}}{\sqrt[n]{a^{k+n-k}}} = \frac{x\sqrt[n]{a^{n-k}}}{\sqrt[n]{a^n}} = \frac{x\sqrt[n]{a^{n-k}}}{|a|} \tag{5.3.114}$$

✍**Example:**

Let us see a world famous example of the application of the root about the origin of the ISO paper formats: A6, A5, A4, A3, A2, A1, A0, etc.

These format of papers have in fact the property (there is a goal at the origin!) to keep the proportions when we bend or cut the sheet in half in its largest dimension. Thus, if we denote by L the length and W the width of the sheet, we have:

$$\frac{L}{W}=\frac{W}{\frac{L}{2}}\Rightarrow L^2=2l^2 \tag{5.3.115}$$

Hence we have:

$$L=\sqrt{2}W \tag{5.3.116}$$

As the A0 format by definition has an area of 1 $[\mathrm{m}^2]$. For this format we have then:

$$LW=1\;[\mathrm{m}^2] \tag{5.3.117}$$

Therefore we deduce that:

$$LW=\sqrt{2}W^2=\frac{L^2}{\sqrt{2}}=1\;[\mathrm{m}^2] \tag{5.3.118}$$

and therefore:

$$W=2^{-1/4}\cdot 1\;[m]\cong 84.1\;[\mathrm{cm}] \tag{5.3.119}$$

from whence we derive:

$$L=2^{-1/4}\cdot 1\;[m]\cong 118.9\;[\mathrm{cm}] \tag{5.3.120}$$

Obviously the reader at this point may ask himself: *What types of algorithms do computers/calculators typically use to compute fractional exponents?*

The basic idea is to use logarithms (see section Analysis page 2284). If $y=x^p$, then:

$$\log(y)=p\log(x) \tag{5.3.121}$$

so:

$$y=e^{p\log(x)} \tag{5.3.122}$$

The actual value of $\log(x)$ and $e^{p\log(x)}$ are then calculated using like a Taylor polynomial (see section Sequences and Series page 1723).

5.3.3 Arithmetic Polynomials

Definition (#5.3.61): An "arithmetic polynomial" (not to be confused with "algebraic polynomial" that will be studied later in the section Calculus page 1368) is a set of numbers separated from each other by the operators of addition or subtraction ($+$ or $-$) including therefore the multiplication...

The components enclosed in the polynomial are known as "terms" of the polynomial. When the polynomial contains a single term, then we speak of "monomial", if there are two terms we speak of "binomial", and so on...

Theorem 5.11. The value of an arithmetic polynomial is equal to the excess of the sum of the terms preceded by the $+$ sign on the sum of the terms preceded by the sign $-$.

Proof 5.11.1.

$$\begin{aligned} n_1 - n_2 + n_3 - n_4 + n_5 - n_6 + \ldots - n_{i-1} + n_i = \\ (n_1 + n_3 + n_5 + \ldots + n_i) \\ + (-1)(n_2 + n_4 + n_6 + \ldots + n_{i-1}) \end{aligned} \tag{5.3.123}$$

whatever the values of the terms.

■ Q.E.D.

Highlight the negative unit -1 is what we name, as we already know, a "factorization". The reverse operation is named as we also already know a "distribution" or "development".

The product of several polynomials can always be replaced by a single polynomial that we name the... "resulting product". We usually operate as follows: we multiply successively all the terms of the first polynomial, starting from the left, with the first, the second, ..., the last by the second polynomial. We obtain a first partial product. We do, if necessary, a reduction (simplification) of similar terms. We then multiply each of the terms of the partial product successively by the first, the second, ..., the last term of the third polynomial starting from the left and so on.

✍**Example:**

$$\begin{aligned}
P_1 \cdot P_2 \cdot P_3 &= (a+b+c)(d+e+f)(g+h+i)\\
&= a(d+e+f)(g+h+f) + b(d+e+f)(g+h+i)\\
&+ c(d+e+f)(g+h+i)\\
&= ad(g+h+i) + ae(g+h+i) + af(g+h+i) + bd(g+h+i)\\
&+ be(g+h+i) + bf(g+h+i) + cd(g+h+i) + ce(g+h+i)\\
&+ cf(g+h+i)\\
&= adg + adh + adi + aeg + aeh + aei + afg + afh + afi + bdg + bdh\\
&+ bdi + beg + beh + bei + bfg + bfh + bfi + cdg + cdh + cdi + ceg + ceh\\
&+ cei + cfg + cfh + cfi
\end{aligned} \tag{5.3.124}$$

The product of the polynomials $P_1, P_2, P_3, \ldots, P_k, \ldots$ is the sum of all products of n_i factors formed with a term of P_i, of a term of P_2, ..., and a term of P_k and so. if there is no reduction, the number of terms is equal to the product of the numbers of terms of each polynomial such that the final number of therms is equals to:

$$n = \prod_{i=1}^{n} n_i \tag{5.3.125}$$

5.3.4 Absolute Value

Definition (#5.3.62): In mathematics, the "absolute value" $|x|$ of a real number x is the non-negative value of x without regard to its sign. Namely, $|x| = x$ for a positive x, $|x| = -x$ for a negative x (in which case $-x$ is positive), and $|0| = 0$. For example, the absolute value of 3 is 3, and the absolute value of -3 is also 3. The absolute value of a number may be thought of as its distance from zero.

Remarks

R1. The term absolute value has been used in this sense from at least 11806 (holocene calendar). The notation $|x|$, with a vertical bar on each side, was introduced by Karl Weierstrass in 11841 (holocene calendar).

R2. For plots about the absolute value, the reader is referred to the Functional Analysis section of this textbook (page 2216).

For any real number x, the "absolute value" x, is formally given by:

$$|x| = \begin{cases} +x & \text{if } x > 0 \\ -x & \text{if } x < 0 \\ 0 & \text{if } x = 0 \end{cases} \tag{5.3.126}$$

At the origin the absolute value was defined as:

$$|x|=\sqrt{x^2} \tag{5.3.127}$$

We notice that also the following possible notation:

$$|x|=\max(-x,x) \tag{5.3.128}$$

And the equivalent expressions:

$$\begin{aligned} x &\leqslant |x| \\ |-x| &= |x| \end{aligned} \tag{5.3.129}$$

and also:

$$\begin{aligned} |x|\leqslant y &\Leftrightarrow -y\leqslant x\leqslant y \\ |x|\geqslant y &\Leftrightarrow x\leqslant -y \vee x\geqslant y \end{aligned} \tag{5.3.130}$$

the latter being often used in the context of solving inequalities.

✍**Example:**

Solving an inequality such that:

$$|x-3|\leq 9 \tag{5.3.131}$$

is then solved simply by using the intuitive concept of distance. The solution is the set of real numbers whose distance from the real number 3 is less than or equal to 9. This is the range of center 3 and radius 9 or formally:

$$[3-9,3+9]=[-6,12] \tag{5.3.132}$$

Let us indicate that it is also useful to interpret the term:

$$\boxed{|x-y|=\sqrt{(x-y)^2}} \tag{5.3.133}$$

as the (euclidean!) distance between the two numbers x and y on the real line. Thus, by providing the set of real numbers of the absolute value distance , it becomes a metric space (see the section of Topology page 2450 to have a robust introduction to what is a distance)!!!

The absolute value has some trivial properties that we will give without proof (excepted on reader request) as they seem to us quite intuitive:

P1. Non-negativity:

$$|x|\geq 0 \tag{5.3.134}$$

P2. Positive-definiteness:

$$|x|=0 \iff x=0 \tag{5.3.135}$$

P3. Multiplicativeness:

$$|xy| = |x||y| \tag{5.3.136}$$

The proof is straightforward:

$$|ab| = \sqrt{(ab)^2} = \sqrt{a^2b^2} = \sqrt{a^2}\sqrt{b^2} = |a||b| \tag{5.3.137}$$

P4. Subadditivity ("first" triangle inequality):

$$|x+y| \leq |x| + |y| \tag{5.3.138}$$

This can be proven in one shot:

$$\begin{gathered}
|a|^2 + |b|^2 + 2|a||b| \geq a^2 + b^2 + 2ab \\
(|a| + |b|)^2 \geq (a+b)^2 \quad \left(\because \forall x \in \mathbb{R}; x^2 = |x|^2\right) \\
||a| + |b|| \geq |a+b| \\
\therefore |a| + |b| \geq |a+b|
\end{gathered} \tag{5.3.139}$$

Other important properties of the absolute value include:

P5. Idempotence (the absolute value of the absolute value is the absolute value):

$$|(|x|)| = |x| \tag{5.3.140}$$

P6. Evenness (reflection symmetry of the graph):

$$|-x| = |x| \tag{5.3.141}$$

The proof is straightforward:

$$|-a| = \sqrt{(-a)^2} = \sqrt{a^2} = |a| \tag{5.3.142}$$

P7. Preservation of division (equivalent to multiplicativeness) if $y \neq 0$:

$$\left|\frac{x}{y}\right| = \frac{|x|}{|y|} \tag{5.3.143}$$

The proof is straightforward:

$$|a \cdot \frac{1}{b}| = \sqrt{\left(a\frac{1}{b}\right)^2} = \sqrt{a^2\left(\frac{1}{b}\right)^2} = \sqrt{a^2}\sqrt{\left(\frac{1}{b}\right)^2} = \frac{|a|}{|b|} \tag{5.3.144}$$

P8. Reverse ("second") triangle inequality (equivalent to subadditivity):

$$|x-y| \geq ||x| - |y|| \tag{5.3.145}$$

For all $x, y \in \mathbb{R}$, the triangle inequality gives:

$$\begin{gathered}
|x| = |x - y + y| \leq |x - y| + |y|, \\
|x| - |y| \leq |x - y|
\end{gathered} \tag{5.3.146}$$

Interchaning $x \leftrightarrow y$ gives:

$$|y|-|x| \leq |y-x| \tag{5.3.147}$$

which when rearranged gives:

$$-(|x|-|y|) \leq |x-y| \tag{5.3.148}$$

Now combining:

$$|x|-|y| \leq |x-y| \quad \text{with} \quad -(|x|-|y|) \leq |x-y| \tag{5.3.149}$$

gives:

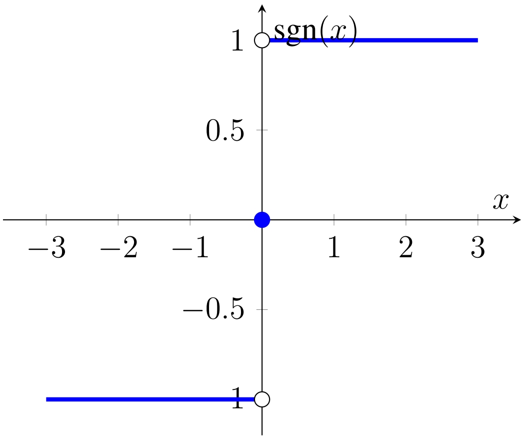
$$-|x-y| \leq |x|-|y| \leq |x-y| \tag{5.3.150}$$

Hence the desired result:

$$||x|-|y|| \leq |x-y| \tag{5.3.151}$$

The absolute function is strongly related to some other functions that we will use quite some times in different section of this textbook. A well known an important example is the "signum function" or "sign function" that is an odd mathematical function that extracts the sign of a real number and defined by:

$$\operatorname{sgn}(x) := \begin{cases} -1 & \text{if } x < 0 \\ 0 & \text{if } x = 0, \\ +1 & \text{if } x > 0. \end{cases} \tag{5.3.152}$$



Alternatively (the signum function is the derivative of the absolute value function, up to the indeterminacy at zero):

$$\operatorname{sgn}(x) = \frac{\mathrm{d}}{\mathrm{d}x}|x|, \quad x \neq 0 \tag{5.3.153}$$

Any real number can be expressed as the product of its absolute value and its sign function:

$$x = \operatorname{sgn}(x) \cdot |x| \tag{5.3.154}$$

5.3.5 Calculation Rules (operators priorities)

Frequently in computing (in development in particular), we speak of "operators precedence". In mathematics we speak of "priority of the sets of operations and rules of signs". What is this exactly?

We have already seen what are the properties of addition, subtraction, multiplication, division and power. We therefore insist that the reader distinguishes the concept of "property" of this of "priority" (that we will immediately see) which are (obviously) two completely different things!

In mathematics, in particular, we first define the priorities of the symbols $\{[()]\}$:

1. Operations that are in parenthesis $()$ should be performed first in the polynomial.
2. Operations that are in brackets $[\,]$ should be made afterwards from the results of operations that were in parenthesis $()$.
3. Finally, from the intermediate results of operations that were in parenthesis $()$ and brackets $[\,]$, we calculate the operations that are between the braces $\{\}$.

Let us do an example, this will be more telling.

✍**Example:**

Consider the calculation of the following arithmetic polynomial:

$$\{[5\cdot(8+2)+3\cdot[4+(8+6)\cdot 2]]\cdot(1+9)\}\cdot 7+1 \tag{5.3.155}$$

According to the rules we defined earlier, we first calculate all the elements that are in parenthesis $()$, that is to say:

$$8+2=10 \quad (8+6)=14 \quad (1+9)=10 \tag{5.3.156}$$

Which give us:

$$\{[5\cdot 10+3\cdot[4+14\cdot 2]]\cdot 10\}\cdot 7+1 \tag{5.3.157}$$

Always according to the rules we defined earlier, now we calculate all the elements between brackets by always starting to calculate the terms that are in brackets $[\,]$ at the lowest level of the other brackets $[\,]$. Thus, we first calculate the expression $[4+14\cdot 2]$ that is in the top-level bracket: $[5\cdot 10+3\cdot\ldots]$.

This gives us $[4+14\cdot 2]=32$ and therefore:

$$\{[5\cdot 10+3\cdot 32]\cdot 10\}\cdot 7+1 \tag{5.3.158}$$

It remains to us to calculate now $[5\cdot 10+3\cdot 32]=146$ and therefore:

$$\{146 \cdot 10\} \cdot 7 + 1 \tag{5.3.159}$$

We now calculate the single term in braces, which gives us:

$$\{146 \cdot 10\} = 1460 \tag{5.3.160}$$

Finally it remains:

$$1460 \cdot 7 + 1 = 10221 \tag{5.3.161}$$

Obviously this is a special case ... But the idea remains the same in general.

The priority of arithmetic operators is a problem mainly related to computer languages (as we have already mentioned) because we can only write mathematical relation on a single line and this is many times as source of confusion for people not having technical skill.

Therefore in computing science, the following expression:

$$\frac{-a \cdot (b+c)^d}{e^f} - g \tag{5.3.162}$$

will be written (pretty much on most computer languages):

$$-a * (b+c)\hat{\ }d/e\hat{\ }f - g \tag{5.3.163}$$

A non initiated could read this in many ways:

$$\frac{-a \cdot (b+c)^d}{e^f} - g; \quad \frac{[-a \cdot (b+c)]^d}{e^f} - g; \quad \left\{\frac{-a \cdot (b+c)^d}{e}\right\}^f - g; \quad [-a \cdot (b+c)]^{\frac{d}{ef}} - g \tag{5.3.164}$$

what you will agree, is very dangerous because we will arrive at different results each time (special cases aside...)!

Thus it has logically be defined an order of prioritization of operators such that the operations are carried out in the following order:

1. $-$ Negation
2. ˆ Power (exponentiation)
3. $*$ Multiplication and $/$ division[16]
4. $\backslash$ Integer division (specific to computer science)
5. mod Modulus (see section Number Theory page 356)
6. $+, -$ Addition and subtraction

---

[16] The *Physical Review* journals, for example, state that in the submission instruction that multiplication is of higher precedence than division!

Obviously the rules of parentheses (), brackets [], and braces {} that were defined in mathematics apply also to computing.

Thus we get in the order (we replace every transaction made with a symbol):

First the terms in parentheses:

$$-a * (b + c)\hat{\ } d/e\hat{\ } f - g = -a * \alpha\hat{\ } d/e\hat{\ } f - g \tag{5.3.165}$$

Afterwards we can apply the priority rules of the operators in the order defined previously:

1. First the negation (rule 1):

$$-a * \alpha\hat{\ } d/e\hat{\ } f - g = \beta * \alpha\hat{\ } d/e\hat{\ } f - g \tag{5.3.166}$$

2. The power (rule 2):

$$\beta * \alpha\hat{\ } d/e\hat{\ } f - g = \beta * \chi/\delta - g \tag{5.3.167}$$

3. We apply the multiplication (rule 3):

$$\beta * \chi/\delta - g = \varepsilon/\delta - g \tag{5.3.168}$$

4. And we apply division (rule 3 again):

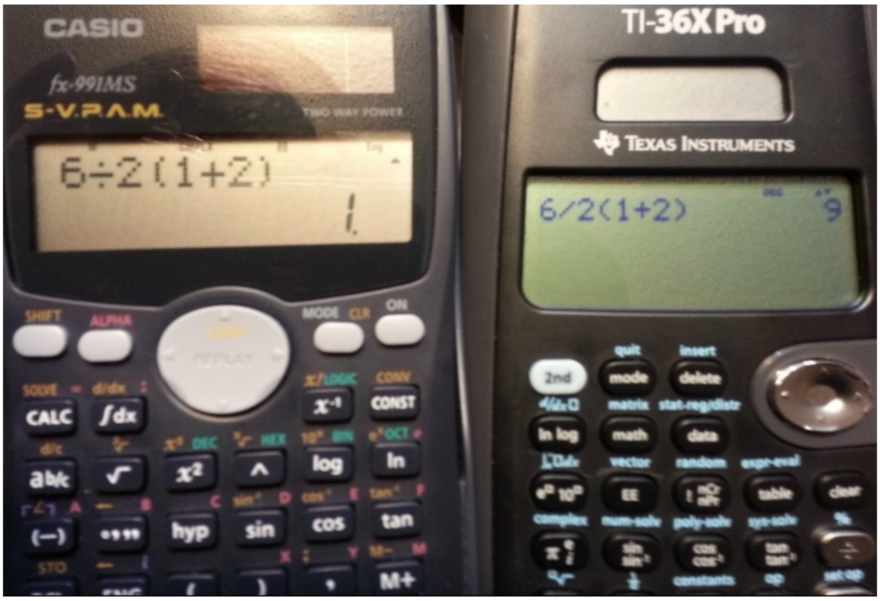
$$\varepsilon/\delta - g = \phi - g \tag{5.3.169}$$

   The rules (4) and (5) does not apply to this particular example.

5. And Finally (rule 6):

$$\phi - g = \varphi \tag{5.3.170}$$

Thus, following these rules, neither a computer nor a human can (should) be wrong in interpreting an equation written on a single line to avoid such issues (hence the important to have ISO standards in all field of the industry and administration):



Remark

Mnemonics are often used to help students in highs-school to remember the most basic rules, but the rules taught by the use of acronyms can be misleading. In the United States, the acronym "PEMDAS" is common. It stands for Parentheses, Exponents, Multiplication, Division, Addition, Subtraction. PEMDAS is often expanded to the mnemonic "Please Excuse My Dear Aunt Sally". Canada and New Zealand use BEDMAS, standing for Brackets, Exponents, Division, Multiplication, Addition, Subtraction. Most common in the UK, India and Australia are BODMAS meaning "B"rackets, "O"f or "O"rder, "D"ivision, "M"ultiplication, "A"ddition and "S"ubtraction. Nigeria and some other West African countries use BIDMAS.

In computer code, however, there are several operators that we do not always find in pure mathematics and which order property frequently change depending from a computer language to another. We will not dwell too much on that stuff as it is almost without end, however, we have below a small description:

- The concatenation operator "&" is evaluated before comparisons operators.
- Comparison operators ($=, <, >, \ldots$) all have equal priority.

However, the leftmost operator in an expression, hold a higher priority.

The logical operators are evaluated in the following order of priority in most computing languages:

1. Not ($\neg$)
2. And ($\wedge$)
3. Or ($\vee$)
4. Xor ($\oplus$)
5. Eqv ($\Leftrightarrow$)
6. Imp ($\Rightarrow$)

Now that we have seen the operator priorities, what are the rules about signs applicable in mathematics and computing science?

First, you must know that these latter rules only apply in the case of multiplication and division. Given two positive numbers $(+x),(+y)$. We have:

$$(+x)\cdot(+y)=(+x)\cdot(+y)=+(x\cdot y) \tag{5.3.171}$$

In other words, the multiplication of two positive numbers is a positive number and this can be generalized to the multiplication of n positive numbers.

We have:

$$(-x)\cdot(+y)=(+x)\cdot(-y)=-(x\cdot y) \tag{5.3.172}$$

In other words, the multiplication of a positive number to a negative number is negative. Which can be generalized: to a positive result of a multiplication if there is an even number of negative numbers, and a negative result if there is an odd number of negative numbers on all n numbers included in the multiplication.

We have:

$$(-x)\cdot(-y)=(-x)\cdot(-y)=+(x\cdot y) \tag{5.3.173}$$

In other words, multiplying two negative numbers is positive. What can be generalized: to a positive result of the multiplication if there is an even number of negative numbers and a negative result if there is an odd number of negative numbers.

About divisions, the reasoning is the same:

$$\frac{(+x)}{(+y)}=+\left(\frac{x}{y}\right) \quad \text{and} \quad \frac{(+y)}{(+x)}=+\left(\frac{y}{x}\right) \tag{5.3.174}$$

In other words, if the numerator and denominator are positive, then the result of the division will be positive.

We have:

$$\frac{(+x)}{(-y)}=\frac{(-x)}{(+y)}=-\left(\frac{x}{y}\right) \quad \text{and} \quad \frac{(-y)}{(+x)}=\frac{(+y)}{(-x)}=-\left(\frac{y}{x}\right) \tag{5.3.175}$$

In other words, if either the numerator or denominator is negative, then the result of the division will be necessarily negative.

We have:

$$\frac{(-x)}{(-y)}=+\left(\frac{x}{y}\right) \quad \text{and} \quad \frac{(-y)}{(-x)}=+\left(\frac{y}{x}\right) \tag{5.3.176}$$

In other words, if the numerator and denominator are positive, then the result of the division, will necessarily be positive.

Obviously if we have a subtraction of terms, it is possible to rewrite it in the form:

$$x-y=x+(-1)y=-1\cdot(-x+y) \tag{5.3.177}$$

5.4. Number Theory

TRADITIONALLY, number theory is a branch of mathematics that deals with properties of integers, whether natural or whole integers. More generally, the field of study of this theory concerns a broad class of problems that naturally come from the study of integers. Number theory can be divided into several branches of study (algebraic number theory, computational number theory, etc.) depending on the methods used and the issues addressed.

Remark

The term "arithmetic" was also used to refer to number theory but it is a fairly old term, which is not as popular as in the past.

We chose to introduce in this section only the subjects that are essential to the study of mathematics and theoretical physics of this textbook as well as those to be absolutely part of the general culture of the engineer (some results have application in Biostatistics!).

5.4.1 Principle of good order

We will take for granted the principle that says that every non-empty set $S \subset \mathbb{N}$ contains a smaller element.

We can use this theorem to prove an important property of numbers named " Archimedean property" or "Archimedes' axiom" which states:

For $\forall a, b \in \mathbb{N}$ where a is non-zero, there is at least one positive integer n such that:

$$n \cdot a \geqslant b \tag{5.4.1}$$

In other words, for two unequal values, there is always an integer multiple of the smallest, bigger than the larger one. We name "Archimedean", structures whose elements satisfy a comparison property (see section Set Theory page 380).

While this is trivial to understand in the case of integers let us prove it because it allows us to see the type of approaches used by mathematicians when they must prove trivial items like this...

Proof 5.11.2. Let us suppose the opposite by saying that for $\forall n \in \mathbb{N}$ we have:

$$n \cdot a < b \tag{5.4.2}$$

If we can prove that it is absurd for any n then we will have prove the Archimedean property (and also if a, b are real).

Let us consider then the set:

$$S = \{b - na | n \in \mathbb{N}\} \tag{5.4.3}$$

Using the principle of good order, we deduce that there exist $s_0 \in S$ such as $s_0 \leq s$ for all $s \in S$. Let us write that this smaller element is:

$$s_0 = b - n_0 a \tag{5.4.4}$$

and therefore we also have:

$$b - (n_0 + 1)a \in S \tag{5.4.5}$$

As by hypothesis $na \leq b$ then we must have:

$$b - (n_0 + 1)a \geq b - n_0 a \tag{5.4.6}$$

and if we reorganize and simplify:

$$-(n_0 + 1) \geq -n_0 \tag{5.4.7}$$

and that we simplify the negative sign we had to get...:

$$n_0 + 1 \geq n_0 \tag{5.4.8}$$

an obvious contradiction!

This contradiction leads that the initial assumption as $na < b$ for all n then is false and therefore the Archimedean property is proved by the absurd.

■ Q.E.D.

5.4.2 Induction Principle

Let S be a set of natural numbers that has the following two properties:

P1. $1 \in S$

P2. If $k \in S$, then $k + 1 \in S$

then:

$$S = \mathbb{N} \setminus \{0\} = \mathbb{N}^* \tag{5.4.9}$$

We are build like this the set of natural numbers (refer to the section Set Theory page 382 to see the rigorous construction of the set of natural number $\mathbb{N}$ with the Zermelo-Fraenkel axioms).

Theorem 5.12. Given now:

$$B = \mathbb{N}^* \setminus S \tag{5.4.10}$$

the symbol "\" meaning for recall "excluding". We want to prove that:

$$B = \varnothing \tag{5.4.11}$$

Again, even if it is trivial to understand, let us do the proof because it allows us to see the type of approaches used by mathematicians when they must prove trivial stuff like this...

Proof 5.12.1. Let us suppose the opposite, that is to say:

$$B \neq \varnothing \tag{5.4.12}$$

By the principle of good order, since $B \subset \mathbb{N}$, B must have a smallest element which we will denote by b_0.

But since $1 \in S$ by the property (P1), we have that $b_0 > 1$ and of course also that $1 \in B$, that is to say also $b_0 - 1 \in S$. By using the property (P2), we finally have $b_0 \in S$, that is to say that $b_0 \notin B$, therefore we get a contradiction.

■ Q.E.D.

✍**Example:**

We want to show thanks to the induction principle, that the sum of the first n square equals $n(n+1)(2n+1)/6$, that is to say for $n \geq 1$, we would have to (see section Sequences and Series page 1667):

$$1+2^2+\ldots+n^2=\sum_{i=1}^{n} i^2=\frac{n(n+1)(2n+1)}{6} \tag{5.4.13}$$

First the above relation is easily verified for $n = 1$ we will show that $n = k + 1$ also verifies that relation. Under the induction hypothesis:

$$\begin{aligned}1^2+2^2+\ldots+k^2+(k+1)^2&=\sum_{i=1}^{k+1} i^2=\frac{k(k+1)(2k+1)}{6}+(k+1)^2\\&=\frac{(k+1)(k+2)(2k+3)}{6}\end{aligned} \tag{5.4.14}$$

although we fall back on the assumption of the validity of the first relation but with $n = k + 1$, hence the result.

This proved process is therefore of great importance in the study of arithmetic. Often observation and induction have led to a suspicion of laws it would have been more difficult to find by a priori. We realize the accuracy of formulas by the previous method that gave birth to modern algebra by Fermat and Pascal studies on the Pascal's triangle (see section Calculus page 1363).

5.4.3 Divisibility

Definition (#5.4.63): Given $A, B \in \mathbb{Z}$ with $A \neq 0$. We say that "A divides B (without rest)" if there is an integer q (the quotient) such that:

$$B = Aq \tag{5.4.15}$$

in which case we write to differentiate of the classic division:

$$A|B \tag{5.4.16}$$

Otherwise, we write (if A doesn't divide B without rest):

$$A \nmid B \tag{5.4.17}$$

and we say that "A does not divide B".

Remarks

R1. Remember that $|$ is a relation when the symbol $/$ is an operation!

R2. Do not confuse the expression "A divides B" which means that rest is necessarily zero and the expression "A is the divisor of the division by B" indicating that the rest is not necessarily zero!

Moreover, if $A|B$, we also say that "B can be divided by A" or "B is a multiple of A".

In case where $A|B$ and that $1 \geq A < B$, we will say that A is a "proper divisor" of B.

Moreover, it is clear that $A|0$ regardless of $A \in \mathbb{Z} \setminus \{0\}$ otherwise what we have a singularity.

Here are some basic theorems relating to the division:

Theorem 5.13. If $A|B$, then $A|BC$ whatever $C \in \mathbb{Z}$. Or more formally:

$$\forall C \in \mathbb{Z} : \quad A|B \Rightarrow A|BC \tag{5.4.18}$$

Proof 5.13.1. If $A|B$, the it exists an integer q such that:

$$B = Aq \tag{5.4.19}$$

Then:

$$BC = (Aq)C = A(qC) \tag{5.4.20}$$

and therefore:

$$A|BC \tag{5.4.21}$$

■ Q.E.D.

Theorem 5.14. If $A|B$ and $B|C$, then $A|C$ or more formally:

$$A|B \wedge A|B \Rightarrow A|C \tag{5.4.22}$$

Proof 5.14.1. If $A|B$ and $B|C$ then, there exists two integers q and r such that $B = Aq$ and $C = Br$. More formally:

$$A|B \wedge B|C \rightarrow \exists(q, r) \in \mathbb{N} : \quad B = Aq \wedge C = Br \tag{5.4.23}$$

Therefore:

$$C = A(qr) \tag{5.4.24}$$

and hence:

$$C = A|C \tag{5.4.25}$$

■ Q.E.D.

Theorem 5.15. If $A|B$ and $A|C$ then:

$$A|(Bx + Cy) \quad \forall x, y \in \mathbb{Z} \tag{5.4.26}$$

Proof 5.15.1. If $A|B$ and $A|C$ then, there exists two integers q and r such that $B = Aq$ and $C = Ar$. It follows:

$$Bx + Cy = (Aq)x + (Ar)y = A(qx + ry) \tag{5.4.27}$$

and therefore:

$$A|(Bx + Cy) \quad \forall x, y \in \mathbb{Z} \tag{5.4.28}$$

■ Q.E.D.

Theorem 5.16. If $A|B$ and $B|A$ then:

$$A = \pm B \tag{5.4.29}$$

Proof 5.16.1. If $A|B$ and $B|A$ then, there exists two integers q and r such that $B = Aq$ and $A = Br$.

We then have:

$$B = B(qr) \tag{5.4.30}$$

and thus $qr = 1$. This is why we can have $q = \pm 1$ if $r = \pm 1$ and thus:

$$A = \pm B \tag{5.4.31}$$

■ Q.E.D.

Theorem 5.17. If $A|B$ and $B \neq 0$ then:

$$|A| \leq |B| \tag{5.4.32}$$

Proof 5.17.1. If $A|B$ then there exist an integer $q \neq 0$ such that $B = Aq$. But then:

$$|B| = |A||q| \geq |A| \tag{5.4.33}$$

as $|q| \geq 1$.

■ Q.E.D.

5.4.3.1 Euclidean Division

The Euclidean division is an operation that, to two integers named respectively the "dividend" and "divisor" combines two other integers named the "quotient" and "remainder". Initially define only for non-zero integers, it can be generalized to relative integers and polynomials, for example.

Definition (#5.4.64): We name "euclidean division" or "integer division" of two numbers A and B the operation of dividing B by A, stopping when the rest is strictly less than A.

Let us recall (see section Numbers page 220) that any number which admits exactly two euclidean divisors (such that division gives no remainder) that are the 1 and itself is named a "prime number" (which excludes the number 1 of the list of primes) and that any pair of numbers which have only 1 as common Euclidean divider are said to be "relatively prime", "mutually prime", or "coprime".

Theorem 5.18. Given $A, B \in \mathbb{Z}$ with $A > 0$. The "theorem of the Euclidean division" state that there are unique integers q (quotient) and r (remainder) such as:

$$B = Aq + r \Leftrightarrow r = B - Aq \tag{5.4.34}$$

where $0 \leq r < A$. Furthermore, if $A \nmid B$, then $0 < r < A$.

✍**Example:**

We have one cake with 9 parts (B), we then have to divide it between 4 people (A) with one part remaining ($r = 1$) such that $q = 2$:

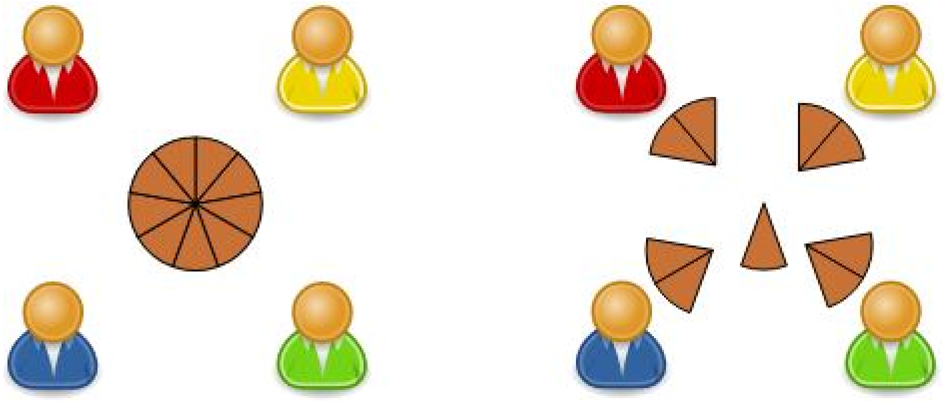

Figure 5.40: **The pie has 9 slices, so each of the 4 people receive 2 slices and 1 is left over**

and therefore:

$$9 = 2 \cdot 4 + 1 \tag{5.4.35}$$

Proof 5.18.1. Let us consider the set:

$$S = \{r = B - qA | q, B \in \mathbb{Z}, A \in \mathbb{Z}^*, B - qA \geq 0\} \tag{5.4.36}$$

It is relatively easy to see that $S \subset \mathbb{N}^* \cup \{0\}$ and that $S \neq \varnothing$, hence, according to the principle of good order, we conclude that S contains a smaller element $r \geq 0$.

Given q the integer satisfying thus:

$$r = B - Aq \tag{5.4.37}$$

We want to first show that $r < A$ assuming the opposite (proof ad absurdum), that is to say that $r \geq A$. So, in this case, we have:

$$B - qA = r \geq A \tag{5.4.38}$$

which is equivalent to:

$$B - (q+1)A = r - A \geq 0 \tag{5.4.39}$$

but $B - (q+1)A \in S$ and:

$$B - (q+1)A < B - qA \tag{5.4.40}$$

This contradicts the fact that:

$$r = B - qA \tag{5.4.41}$$

is the smallest element of S. So $r < A$. Finally, it is clear that if $r = 0$, we have $A|B$, hence the second statement of the theorem.

■ Q.E.D.

Remark

In the statement of the Euclidean division, we assumed that $A > 0$. What do we get when $A < 0$? In this situation, $-A$ is obviously positive, and then we can apply the Euclidean division to B and $-A$. Therefore, there are integers q and r integers such that:

$$B = q(-A) + r \tag{5.4.42}$$

where $0 \geq r < |A|$. But this relation can be written:

$$B = -q(A) + R \tag{5.4.43}$$

where obviously, $-q$ is an integer. The conclusion is that the Euclidean division can be stated in a more general form.

Given $A, B \in \mathbb{Z}$, there exist two integers q and r such that:

$$B = Aq + r \tag{5.4.44}$$

where $0 \geq r < |A|$. Furthermore, if $A \nmid B$, then $0 < r < |A|$

The integers q and r are unique in the Euclidean division. Indeed, if there are two other integers q' and r' such as:

$$B = Aq' + r' \tag{5.4.45}$$

always with $0 \leq r' < A$, then:

$$A(q'-q) = r - r' \tag{5.4.46}$$

and therefore:

$$A|(r-r') \tag{5.4.47}$$

Following the previous theorem we have if $r - r' \neq 0$ that $|r - r'| \geq A$.

But, this last inequality is impossible as by construction $-A < r - r'$. Therefore $r = r'$ and, as $A \neq 0$, then $q' = q$ hence the unicity.

In mathematics and more precisely in Set Algebra, in the context of ring theory, a ring is named an "Euclidean ring" if it is possible to define a Euclidean division in it. The relative integers form the most simplest case of Euclidean ring. This set verifies the following property:

$$\forall a \in \mathbb{Z} \quad \forall b \in \mathbb{Z}\backslash\{0\} \quad \exists q, r \in \mathbb{Z} \quad \text{such that} \quad a = bq + r \quad \text{and} \quad |r| < |b| \tag{5.4.48}$$

The reader must remember that natural numbers with addition and multiplication as the operations do not form a ring or a field. They don't form a ring because addition does not have inverses in the natural numbers which is a property required for a ring. Hence the fact that the smallest Euclidean ring is the made of relative integers!

5.4.3.1.1 Greatest common divisor

The "greatest common divisor" (gcd) (also known as "greatest common factor" (gcf), "highest common factor" (hcf), "greatest common measure" (gcm), or "highest common divisor") of two or more integers, when at least one of them is not zero, is the largest positive integer that divides the numbers without a remainder.

Definition (#5.4.65): Given $a, b \in \mathbb{Z}$ such as $ab \neq 0$. The "greatest common divisor" (gc) of a and b, denoted:

$$(a, b) \tag{5.4.49}$$

is the positive integer n that satisfies the following two properties:

P1. $d|a$ and $d|b$ (so without remainder r in the division!)

P2. If $c|a$ and $c|b$ then $c \leq d$ and $c|d$ (by definition!)

Note that 1 is always a common divisor of two arbitrary integers.

✍**Example:**

Let us consider the positive integers 36 and 54. A common divisor of 36 and 54 is a positive integer that divides 36, and also 54. For example, 1 and 2 are common divisors 36 and 54.

$$\begin{aligned}\text{Div}_{36}&=\{1,2,3,4,6,9,12,18,36\}\\ \text{Div}_{54}&=\{1,2,3,6,9,18,27,54\}\end{aligned}\qquad(5.4.50)$$

We have the intersection represented by the following Venn diagram (see section Set Theory page 378):

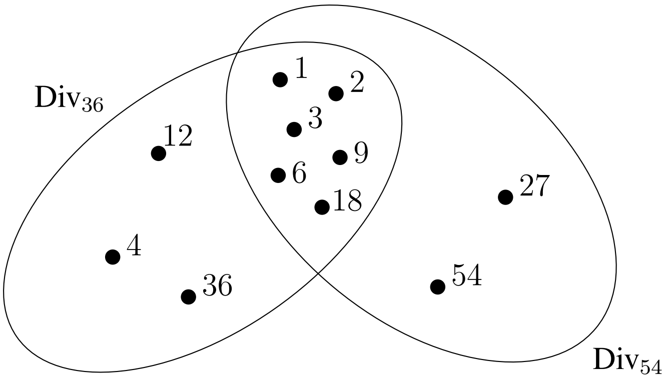

Figure 5.41: **Venn diagram of common divisors**

with the following set of common divisors:

$$\text{Div}_{36}\cap\text{Div}_{54}=\{1,2,3,6,9,18\}\qquad(5.4.51)$$

and hence, the highest common factor is:

$$\max\{1,2,3,6,9,18\}=18\qquad(5.4.52)$$

and we find that the set of common divisors of 36 and 54 is also the set of dividers of 18.

However it is not necessarily obvious that the greatest common divisor other than 1 of two integers a and b that are not relatively prime always exists. This is proved by the following theorem (however, if the gcd exists, it is by definition unique!) named "Bézout's theorem" that can also gives the opportunity to prove other interesting properties of two numbers as we shall see later.

Theorem 5.19. Given $a, b \in \mathbb{Z}$ such that $ab \neq 0$. If d divides a and d divides b (for both without remainder r !) then there must two integers x and y such that:

$$\boxed{d=(a,b)=ax+by}\qquad(5.4.53)$$

This relation is named the "Bézout's identity" and it is a linear Diophantine equation (see section Calculus page 1378).

Proof 5.19.1. Obviously, if a and b are relatively prime we know that d is then 1.

To prove the Bézout identity let first consider the set:

$$S=\{d=ax+by|x,y\in\mathbb{Z},ax+by>0\}\qquad(5.4.54)$$

As $S \subset \mathbb{N}$ and $S \neq \varnothing$, we can use the principle of good order and conclude that S has a smaller element d. We can then write:

$$d = ax_0 + by_0 \tag{5.4.55}$$

for some given choice $x_0, y_0 \in \mathbb{Z}$. So it is sufficient to prove that $d = (a, b)$ to prove the Bézout identity!

Let us proceed with a proof by contradiction by assuming $d \nmid a$. Then if this is the case, following the Euclidean division, there exist $q, r \in \mathbb{Z}$ such as $a = qd + r$, where $0 < r < d$. But then:

$$r = a - qd = a - q(ax_0 + by_0) = a(1 - qx_0) + b(-qy_0) \tag{5.4.56}$$

Thus we have that $r \in S$ and $r < d$, which contradicts the fact that d is the smallest possible element of S. Thus we have proven not only that $d|a$, but also that d always exists and, in the same way we prove that $d|b$.

■ Q.E.D.

Corollary 5.19.1. As important corollary let us now prove that if $a, b \in \mathbb{Z}$ such that $ab \neq 0$, then:

$$S = \{ax + by | x, y \in \mathbb{Z}\} \tag{5.4.57}$$

is the set of all multiples of $d(a, b)$.

Proof 5.19.2. As $d|a$ and $d|b$, then we have necessarily $dax + by|$ for any $x, y \in \mathbb{Z}$. Either $M = \{nd|n \in \mathbb{Z}\}$. Our problem is then reduced to prove the fact that $S = M$.

Given first $s \in S$ which means that $d|s$ and involves $s \in M$.

Given a $m \in M$, this would mean that $m = nd$ for a certain $n \in \mathbb{Z}$.

As $d = ax_0 + by_0$ for any choice of integers $x_0, y_0 \in \mathbb{Z}$, then:

$$m = nd = n(ax_0 + by_0) = a(nx_0) + b(ny_0) \in S \tag{5.4.58}$$

■ Q.E.D.

The assumptions may seem complicated but put your attention a given time on the last equality. You will quickly understand!

Remark

If instead of defining the greatest common divisor of two non-zero integers, we allow one of them to be equal to 0, say: $a \neq b$, $b = 0$. In this case, we have $a|b$ and, according to our definition of the GCD, it is clear that $(a, 0) = |a|$.

Given $d = (a, b)$ and $m \in \mathbb{Z}$, then we have the following properties of the GCD (without proof but if a reader request them we will give the details):

P1. $(a,b+ma)=(a,b)=(a,-b)$

P2. $(am,bm)=|m|(a,b)$ where $m\neq 0$

P3. $\left(\dfrac{a}{d},\dfrac{b}{d}\right)=1$

P4. If $g\in\mathbb{Z}\setminus\{0\}$ such that $g|a$ and $g|b$ then $\left(\dfrac{a}{g},\dfrac{b}{g}\right)=\dfrac{1}{|g|}(a,b)$

In some books, these four properties are proved using intrinsically the property itself. Personally we abstain make usage of this approach because doing this is more ridiculous than anything else as the statement of the property is a proof in itself.

✍**Example:**

In a bathroom, a high-end client wants to cover the wall above the bathtub with a whole number of (very expensive) square-shaped earthenware tiles whose side is a whole number of centimetres as large as possible. Knowing that the wall is 210 [cm] high and 135 [cm] wide, what is the length, in centimetres, of the side of a tile. How many tiles will then be needed?

For the number of tiles to be a whole number, the size of a tile must be a common divisor of both 210 and 135. The largest possible size corresponds to the GCD of 210 and 135, we need tiles with a side of 15 [cm]. So we will need $210/15=14$ tiles in height and $135/15=9$ tiles in width. So a total of $14\cdot 9=126$ tiles.

Let us now develop a method (algorithm) that will be very useful to us to calculate (determine) the greatest common divisor of two integers (sometimes useful computing science).

5.4.3.2 Euclidean Algorithm

The Euclidean algorithm is an algorithm for determining the greatest common divisor of two integers (we have hesitate to put this subject in the section of Theoretical Computing...).

To address this method intuitively, you must know that you need to see that an integer as a length, a pair of integers as a rectangle (sides) and their GCD is the size of the largest square for tile (paving) their rectangle by definition (yes if you think for a moment it's quite logical!).

The algorithm decomposes the original rectangle into squares, always smaller and smaller, by successive Euclidean division of the length by the width, then the width by the remainder until a zero remainder. We must understand this geometric approach to then understand the algorithm.

✍**Example:**

Let us consider that we seek the GCD of (a,b) where b is equal 21 and a is equal 15 and keep in mind that the GCD, besides the fact that it divides a and b, must leave a zero remainder! In other words it must divide the remainder of the division of b by a also!

So we have the following rectangle of 21 by 15:

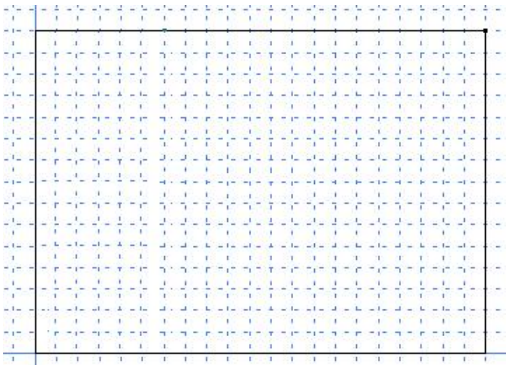

Figure 5.42: **First step of the GCD algorithm**

First we see if 15 is the GCD (it always starts with the smallest). We then divide 21 by 15, which is equivalent geometrically to:

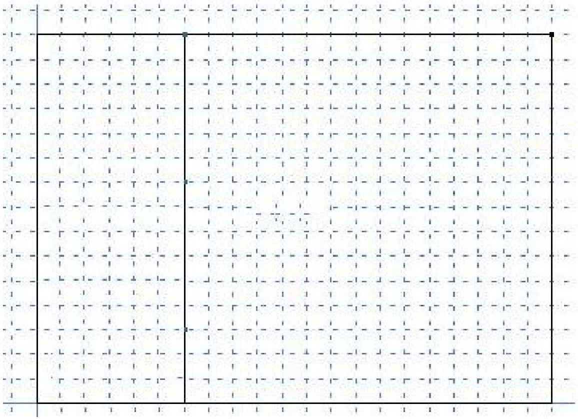

Figure 5.43: **Second step of the GCD algorithm**

15 is therefore not the GCD (we suspected it...). We immediately see that we can not pave the rectangle with a square of 15 by 15.

So we have a remainder of 6 (left rectangle). The GCD as we know must, if it exists, by definition divide that remains and leave a zero remainder.

So we have a rectangle of 15 by 6. So we are looking now to pave this new rectangle because we know that the greatest common divisor is by construction less than or equal to 6. Then we have:

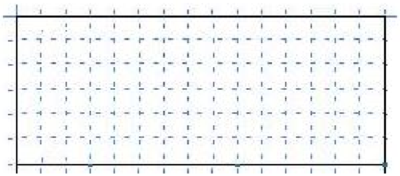

Figure 5.44: **Third step of the GCD algorithm**

So we divide 15 by remainder 6 (this result will be less than 6 and immediately permits to tests whether the remainder will be the GCD). We are getting:

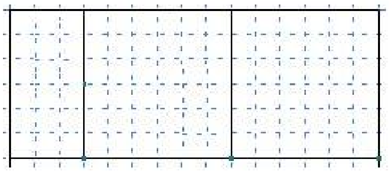

Figure 5.45: **Fourth step of the GCD algorithm**

Again, we can not pave the rectangle only with squares. In other words, we have a non-zero remainder which is 3. Given now a rectangle of 6 by 3. So we are looking now to pave the new rectangle because we know that the greatest common divisor is by construction less than or equal to 3 and that it will leave a remainder equal to zero, if it exists. We then have geometrically:

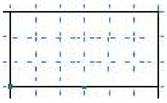

Figure 5.46: **Fifth step of the GCD algorithm**

We divide 6 by 3 (which will be less than 3 and permits us to test immediately whether the rest will be the GCD):

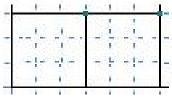

Figure 5.47: **Sixth step of the GCD algorithm**

and it's all good! We then have 3 that leaves us with a remainder equal to zero and divides the remainder 6 so this is the GCD. So we have in the end:

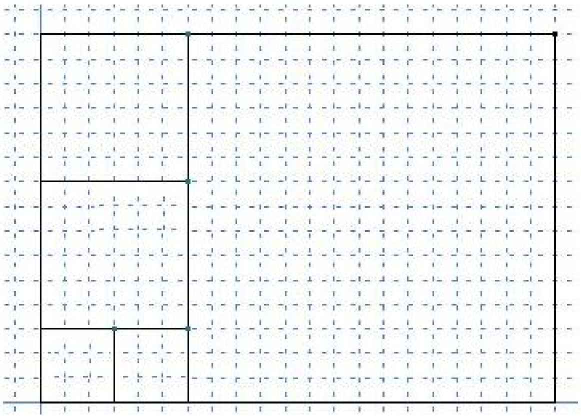

Figure 5.48: **Summary of the GCD algorithm**

Now let us see the equivalent formal approach.

Given $a,b\in\mathbb{Z}$, where $a>0$. Applying successively the Euclidean division (with $b>a$), we get the following sequence of equations:

$$\begin{aligned} b &= qa_1 + r_1 & 0 < r_1 < a \\ a &= r_1 q_2 + r_2 & 0 < r_2 < r_1 \\ r_1 &= r_1 2 q_3 + r_3 & 0 < r_3 < r_2 \\ &\ldots \\ r_{j-2} &= r_{j-1} q_j + r_j & 0 < r_j < r_{j-1} \\ r_{j-1} &= r_j q_{j+1} \end{aligned} \tag{5.4.59}$$

if $d = (a, b)$, then $d = r_j$. With the corresponding pseudocode algorithm:

Algorithm 1: GCD pseudocode algorithm

```
Data: $a$,$b$
Result: $b$
initialization;
$r = a \mod b$;
while $r \neq 0$ do
    $a := b$;
    $b := r$;
    $f(b) := f(a)$;
    $a := x_1$;
    $f(a) := f(x_1)$;
Display $x_1$;
```

Otherwise even more formally:

Proof 5.19.3. We want first prove that $r_j = (a, b)$. But, following the property P1:

$$(a, b + ma) = (a, b) = (a, -b) \tag{5.4.60}$$

we have:

$$(a, b) = (a, r_1) = (r_1, r_2) = \ldots = (r_{j-1}, r_j) \tag{5.4.61}$$

To prove the second property of the Euclide's algorithm, we write the prior-previous equation of the system under the form:

$$r_j = r_{j-2} - q_j r_{j-1} \tag{5.4.62}$$

Now, using the previous equation this prior-previous equation of the system, we have:

$$r_j = r_{j-2} - q_j(r_{j-3} - q_{j-1} r_{j-2}) = (1 + q_j q_{j-1}) r_{j-2} + (-q_j) r_{j-3} \tag{5.4.63}$$

Continuing this process, we can express r_j as a linear combination of a and b.

■ Q.E.D.

✍**Example:**

Let us calculate the greatest common divisor of $(429, 966)$ and express this number as a linear combination of 429 and 966.

We apply obviously Euclide's algorithm:

$$\begin{aligned}966 &= 429 \cdot 2 + 108\\ 429 &= 108 \cdot 3 + 105\\ 108 &= 105 \cdot 1 + 3\\ 105 &= 35 \cdot 3\end{aligned} \tag{5.4.64}$$

We therefore conclude that:

$$r_j = d = (966, 429) = 3 \tag{5.4.65}$$

and, in addition, that:

$$\begin{aligned}3 &= 108 - 105 \cdot 1 = 108 - (429 - 108 \cdot 3) = 108 \cdot 4 - 429\\ &= (966 - 429 \cdot 2) \cdot 4 - 429\\ &= 966 \cdot 4 - 429 \cdot 9 = 966 \cdot 4 + 429 \cdot (-9)\end{aligned} \tag{5.4.66}$$

Thus the GCD is indeed expressed as a linear combination of a and b and constitutes as such the GCD.

Definition (#5.4.66): We say that the integers $a_1, a_2, \ldots, a_n$ are for recall "relatively prime" if:

$$(a_1, a_2, \ldots, a_n) = 1 \tag{5.4.67}$$

5.4.3.3 Least Common Multiple

The least common multiple (also named the "lowest common multiple" or "smallest common multiple") of two integers a and b, usually denoted by $\text{LCM}(a, b)$, is the smallest positive integer that is divisible by both a and b. Since division of integers by zero is undefined, this definition has meaning only if a and b are both different from zero.

The LCM is familiar from grade-school arithmetic as the "lowest common denominator (LCD)" (also named "smallest common denominator") that must be determined before fractions can be added, subtracted or compared. The LCM of more than two integers is also well-defined: it is the smallest positive integer that is divisible by each of them.

For example, to perform the calculation:

$$\frac{65}{18372} - \frac{21}{15310} \tag{5.4.68}$$

We can reduce the fractions to a common denominator. In the absence of another method, we write:

$$\frac{65}{18372}-\frac{21}{15310}=\frac{65\cdot 15310}{18372\cdot 15310}-\frac{21\cdot 18372}{15310\cdot 18372}=\frac{995150}{281275320}-\frac{385812}{281275320}=\frac{609338}{281275320} \tag{5.4.69}$$

We then simplify:

$$\frac{609338}{281275320} \tag{5.4.70}$$

by finding a common divisor between 609338 and 281275320 (...) and we get:

$$\frac{199}{91860} \tag{5.4.71}$$

If we had been able to anticipate that 91860 was a common multiple of 18372 and 15310 (and even that it was the smallest common multiple!), the calculations would have been much easier.

Indeed, since 91860 is equal to $18372\cdot 5$ and to $15310\cdot 6$, we could have written:

$$\frac{65}{18372}-\frac{21}{15310}=\frac{65\cdot 5}{18372\cdot 5}-\frac{21\cdot 6}{15310\cdot 6}=\frac{325}{91860}-\frac{126}{91860}=\frac{199}{91860} \tag{5.4.72}$$

Therefore, finding the common multiples of two numbers is of definite interest for calculation when we don't have any computer assistance!

Definitions (#5.4.67):

D1. Given $a_1,a_2,\ldots,a_n\in\mathbb{Z}\setminus\{0\}$, we say that m is a "common multiple" of $a_1,a_2,\ldots,a_n$ if $a_i|m$ for $i=1,2,\ldots,n$

D2. Given $a_1,a_2,\ldots,a_n\in\mathbb{Z}\setminus\{0\}$, we name "lowest common multiple" (LCM) of $a_1,a_2,\ldots,a_n$ if $a_i|m$ for $i=1,2,\ldots,n$ denoted traditionally by:

$$[a_1,a_2,\ldots,a_n] \tag{5.4.73}$$

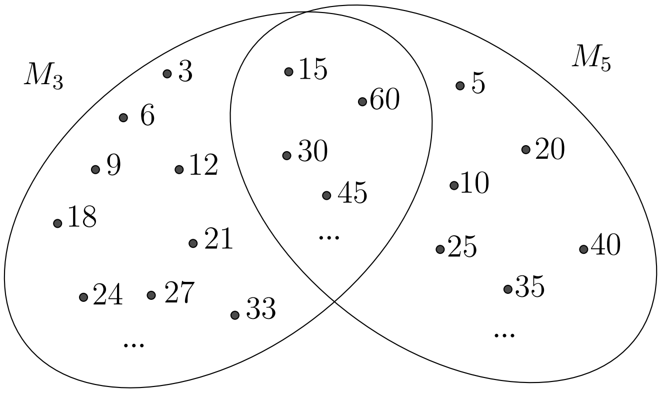
the lowest integer positive common multiple to all common multiples of $a_1,a_2,\ldots,a_n$.

✍**Examples:**

E1. Let us consider the positive integers 3 and 5. A common multiple of 3 and 5 is a positive integer which is both a multiple of 3, and a multiple of 5. In other words, which is divisible by 3 and 5. We have therefore:

$$\begin{aligned}M_3&=\{3,6,9,12,15,18,21,24,27,30,\ldots\}\\M_5&=\{5,10,15,20,25,30,35,40,45,\ldots\}\end{aligned} \tag{5.4.74}$$

We then have the intersection represented by the following Venn diagram (see section Set Theory 378):



M_3
3
6
9
12
18
21
24
27
33
...
15
60
30
45
...
M_5
5
20
10
25
40
35
...

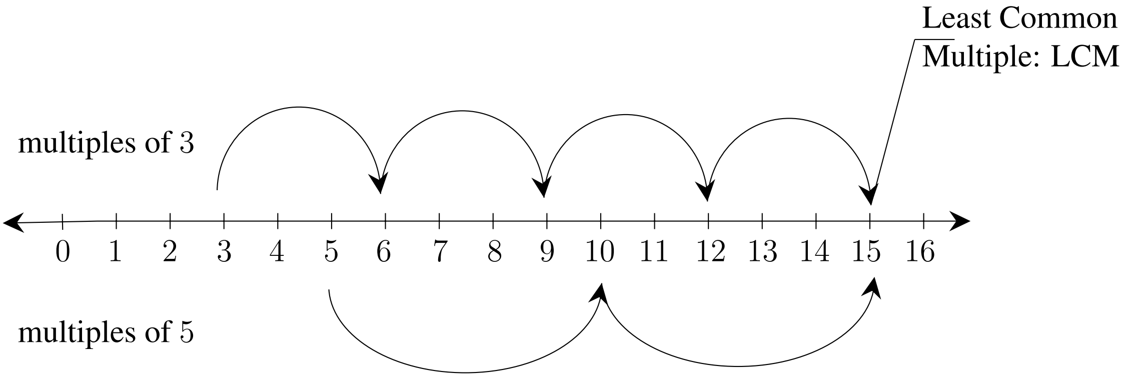
we then have the following set of common multiples:

$$M_3 \cap M_5 = \{15, 30, 45, 60, \ldots\} \tag{5.4.75}$$

and therefore the LCM is given by:

$$\text{LCM} = \min\{15, 30, 45, 60, \ldots\} = 15 \tag{5.4.76}$$

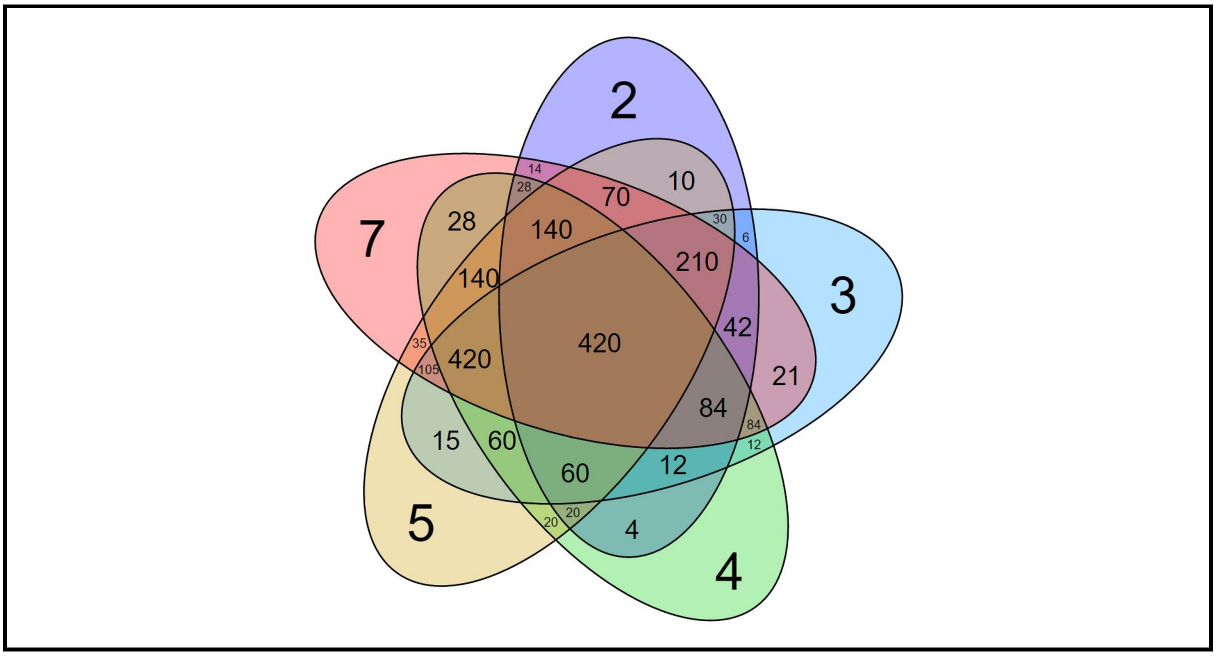
Or if it can help here is another possible visualization of the concept:



Least Common
Multiple: LCM
multiples of 3
0
1
2
3
4
5
6
7
8
9
10
11
12
13
14
15
16
multiples of 5

We see obviously that all the common multiples of 3 and 5 is the set of multiples of 15.

E2. Wikipedia gives also a nice example of a Venn Diagram (see section Set Theory page 378) when we seek for a LCM of 5 multiples using a visual tool:



Remark

Given $a_1, a_2, \ldots, a_n \in \mathbb{Z} \setminus \{0\}$. Then the least common multiple exists. Indeed, consider the set E of natural integers m that for all i divide a_i. What we will write:

$$E = \{m|a_i|m \in \mathbb{N}, i = 1, 2, \ldots, n\} \tag{5.4.77}$$

Since we have necessarily $|a_1 a_2 \ldots a_n| \in E$, then the set is not empty and, according to the axiom of good order, the set E contains a smaller positive element.

Let us now see some theorems related to the LCM:

Theorem 5.20. If m is any common multiple of $a_1, a_2, \ldots, a_n$ then $[a_1, a_2, \ldots, a_n]|m$ that is to say that m divides each of the a_i.

Proof 5.20.1. Given $M = [a_1, a_2, \ldots, a_n]$. Then, by the Euclidean division, there are integers q and r such that:

$$m = qM + r \quad 0 \leq r < M \tag{5.4.78}$$

It suffices to show that $r = 0$. Let us suppose that $r \neq 0$ (reductio ad absurdum). Since $a_i|m$ and $a_i|M$, then we have $a_i|r$ and this for $i = 1, 2, \ldots, n$. So r is common multiple of $a_1, a_2, \ldots, a_n$ of the smallest than the LCM. We just obtained a contradiction, which proves the theorem.

■ Q.E.D.

Theorem 5.21. If $k > 0$, then $[ka_1, ka_2, \ldots, ka_n] = k[a_1, a_2, \ldots, a_n]$

The proof will be assumed obvious (if not as always contact us and will add the details!)

Theorem 5.22. $[a, b] \cdot (a, b) = |ab|$. Or more explicitly: LCM$(a; b) \cdot$ GCD$(a; b) = |a \cdot b|$.

Proof 5.22.1.

Lemma 5.22.1. For this proof, we will use the "Euclid's lemma" that says that if $a|bc$ and $(a, b) = 1$ then $a|c$.

In other words Euclid's lemma captures a fundamental property of prime numbers, namely: If a prime divides the product of two numbers, it must divide at least one of those numbers. It is also named "Euclid's first theorem". This lemma is the key of the proof of the fundamental theorem of arithmetic that we will see just further below!

Indeed, this can be easily verified because we have seen that there exists $x, y \in \mathbb{Z}$ such as $1 = ax + by$ and then $c = acx + bcy$. But $a|ac$ and $a|bc$ imply that $a|(acx + bcy)$, that is to say also that $a|c$.

Ok let us now return to our theorem:

Since $(a, b) = (a, -b)$ and $[a, b] = [a, -b]$, it suffices to prove the result for positive integers a and b.

First of all, let consider the case where $(a, b) = 1$. The integer $[a, b]$ being a multiple of a, we can write $[a, b] = ma$. Thus, we have $b|ma$ and since $(a, b) = 01$, it follows, by Euclid's lemma, that $b|m$. Therefore, $b \leq m$ and then $ab \leq am$. But ab is a common multiple of a and b that can not be smaller than the LCM. therefore $ab = ma = [a, b]$.

For the general case, that is to say $(a, b) = d > 1$, we have, according to the property:

$$\left(\frac{a}{d}, \frac{b}{d}\right) = 1 \tag{5.4.79}$$

and with the result obtained previously that:

$$\left[\frac{a}{d}, \frac{b}{d}\right]\left(\frac{a}{d}, \frac{b}{d}\right) = \frac{a}{d}\frac{b}{d} \tag{5.4.80}$$

When we multiply both sides of the equation by d^2, the result follows and the proof is done.

■ Q.E.D.

Here are some trivial properties that we give without proof:

P1. $\text{LCM}(a; b) = \text{LCM}(b; a)$

P2. If b is a multiple of a, then $\text{LCM}(a; b) = b$

P3. If a and b are mutually prime, then we have $\text{LCM}(a; b) = a \cdot b$

P4. If k is a natural integer, then we have $\text{LCM}(ka; kb) = k\text{LCM}(a; b)$ (homogeneity)

5.4.3.4 Fundamental Theorem of Arithmetic

The fundamental theorem of arithmetic says that every natural number $n > 1$ can be written as a product of primes, and this representation is unique, except for the order in which the prime factors are arranged.

The theorem establishes the importance of prime numbers. Essentially, they are the building blocks of building positive integers, each positive integer containing primes in a unique way.

Remark

This theorem is sometimes named "factorization theorem" (wrongly ... because some other theorems have the same name ...).

So let's go:

Theorem 5.23. Every integer greater than 1 either is prime itself or is the product of prime numbers, and that this product is unique, up to the order of the factors.

Remark

This theorem is one of the main reasons why 1 is not considered a prime number: if 1 were prime, the factorization would not be unique.

Proof 5.23.1. The proof uses Euclid's lemma: if a prime p divides the product of two natural numbers a and b, then either p divides a or p divides b (or both).

If n is prime, and therefore product of a unique prime integer, namely itself, the result is true and the proof is complete (say that a prime number is product of itself is obviously a misnomer!). Suppose that n is not prime and therefore strictly greater than 1 and consider the set:

$$D = \{d|n \text{ and } 1 < d < n\} \tag{5.4.81}$$

So, $D \subset \mathbb{N}$ and since n is composite, we have that $D \neq \varnothing$. According to the principle of good order, D has a smaller element p_1 that is prime, otherwise the minimum choice of p_1 is contradicted. We can the write $n = p_1 n_1$. If n_1 is prime, then the proof is complete. If n_1 is also composite, then we repeat the same argument as before and we deduce the existence of a prime number p_2 and of an integer $n_2 < n_1$, such as $n = p_1 p_2 n_2$. By continuing we come inevitably to the conclusion that n_k will be prime.

So finally we have well shown that any number can be decomposed into prime numbers factors with the principle of good order.

■ Q.E.D.

We do not know to this day a simple law that allows to calculate the n-th prime factor p_n. Thus, to know if an integer m is a prime, it is almost easier at this date to verify its presence in a table of prime numbers.

In fact, we use nowadays the following method:

Given an integer m, if we want to determine whether it is prime or not, we calculate if it is divisible by the primes number p_n belonging to the set:

$$\{p_n \in \mathbb{N} | p_n < \sqrt{M}\} \tag{5.4.82}$$

✍**Example:**

The integer 223 is neither divisible by 2 or by 3 or by 5 or by 7, or by 11, or by 13. It is useless to continue with the next prime number, because $17^2 = 289 > 223$. We conclude therefore that the number 223 is prime.

We can now address the concept of "set of divisors ". In $\mathbb{N}$ the set of division of 200 is $\{1; 2; 4; 5; 8; 10; 20; 25; 40; 50; 100; 200\}$.

We can derive this result from the prime factorization of 200. Indeed, this factorization is:

$$200 = 2^3 \cdot 5^2 \tag{5.4.83}$$

We can then verify that the divisors of 200 are the numbers that can be written in the form $2^{\beta_1}5^{\beta_2}$ with $0 \leq \beta_1 \leq 3$ and $0 \leq \beta_2 \leq 2$.

Theorem 5.24. Given n an integer greater than or equal to 2, whose decomposition in prime factors is $n = {p_1}^{\alpha_1}{p_2}^{\alpha_2}\ldots p_k^{\alpha_k}$. Set set of natural divisors of n is the set of integers d that can be writtent as $d = p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k}$ where $\beta_1, \beta_2, \ldots, \beta_k$ are natural integers such that $0 \leq \beta_1 \leq \alpha_1, 0 \leq \beta_2 \leq \alpha_2, \ldots, 0 \leq \beta_k \leq \alpha_k$.

Proof 5.24.1. n is an integer greater than or equal to 2, whose prime factorization is:

$$n = p_1^{\alpha_1}p_2^{\alpha_2}\ldots p_k^{\alpha_k} \tag{5.4.84}$$

Let us consider an integer d written in the form:

$$d = p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta k} \tag{5.4.85}$$

where $\beta_1, \beta_2, \ldots, \beta_k$ are natural integers such that $0 \leq \beta_1 \leq \alpha_1, 0 \leq \beta_2 \leq \alpha_2, \ldots, 0 \leq \beta_k \leq \alpha_k$.

We can then write:

$$n = p_1^{\alpha_1}p_2^{\alpha_2}\ldots p_k^{\alpha_k} = \left(p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k}\right) \cdot \left(p_1^{\alpha_1-\beta_1}p_2^{\alpha_2-\beta_2}\ldots p_k^{\alpha_k-\beta_k}\right) \tag{5.4.86}$$

Hence:

$$n = d \cdot q \tag{5.4.87}$$

with:

$$q = p_1^{\alpha_1-\beta_1}p_2^{\alpha_2-\beta_2}\ldots p_k^{\alpha_k-\beta_k} \tag{5.4.88}$$

We know that $\beta_1, \beta_2, \ldots, \beta_k$ are natural integers such that $0 \leq \beta_1 \leq \alpha_1, 0 \leq \beta_2 \leq \alpha_2, \ldots, 0 \leq \beta_k \leq \alpha_k$.

Hence $\alpha_1 - \beta_1; \alpha_2 - \beta_2; \ldots; \alpha_k - \beta_k$ are natural integers.

Therefore, q is a natural number and d is therefore a divisor of n.

Consider an integer d that is a divisor of n:

- If $d=1$, d can be written as $d=p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k}$ with $\beta_1=\beta_2=\ldots=\beta_k=0$.
- If $d>1$, given $d=q_1^{\gamma_1}q_2^{\gamma_2}\ldots q_r^{\gamma_r}$ the decomposition of d in prime factorization.

  Then $q_1,q_2,\ldots,q_r$ are prime divisors of d, therefore they are prime divisors of n, so these are some of the numbers $p_1,p_2,\ldots,p_k$. We can then write $d=p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k}$ where $\beta_1,\beta_2,\ldots,\beta_k$ are natural integers.

  If the number p_i does not appear in the decomposition of d, then we have $\beta_i=0$.

Let us prove that we have then that $\beta_1\leq\alpha_1$:

We know that d divides n, and $p_1^{\beta_1}$ divides d, therefore $p_1^{\beta_1}$ divides n, hence $p_1^{\beta_1}$ divides $p_1^{\alpha_1}p_2^{\alpha_2}\ldots p_k^{\alpha_k}$.

By contradiction (reductio ad absurdum), if β_1 was striclty greater than α_1, then $p_1^{\beta_1-\alpha_1}$ would divide $p_2^{\alpha_2}\ldots p_k^{\alpha_k}$ threfore p_1 would divide $p_2^{\alpha_2}\ldots p_k^{\alpha_k}$, which is not possible since p_1 is not one of the numbers $p_2,\ldots,p_k$.

We have therefore $\beta_1\leq\alpha_1$. Similarly, we can justify that $\beta_2\leq\alpha_2,\ldots,\beta_k\leq\alpha_k$ following the same procedure.

Therefore d can be written as $d=p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k}$ where $\beta_1,\beta_2,\ldots,\beta_k$ are natural integers such as $0\leq\beta_1\leq\alpha_1,0\leq\beta_2\leq\alpha_2,\ldots,0\leq\beta_k\leq\alpha_k$...

■ Q.E.D.

Remark

If n has a prime factorization $n=p_1^{\alpha_1}p_2^{\alpha_2}\ldots p_k^{\alpha_k}$, the number of natural divisors of n is then $(\alpha_1+1)\cdot(\alpha_2+1)\cdot\ldots\cdot(\alpha_k+1)$.

Indeed, every natural divisor can be written $p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k}$ and every number β_i can take the (α_i+1) values from 0 to α_i.

The prime factorization of 200 is: $200=2^3\cdot 5^2$.

This allows us to say that the number of natural divisors of 200 is: $(3+1)\cdot(2+1)=4\cdot 3=12$.

Thanks to this fundamental theorem we can prove powerful results on the GCD and LCM, the proof of which is also very instructive from a methodological point of view.

Let us begin by recalling that Euclid's algorithm, seen above, allows us to justify that:

$$\text{GCD}(1'500;4'725)=75 \tag{5.4.89}$$

We have also proved earlier above that:

$$\text{GCD}(a;b)\cdot\text{LCM}(a;b)=a\cdot b \tag{5.4.90}$$

Hence:

$$\text{GCD}(1,500;4,725)\cdot\text{LCM}(1,500;4,725)=1,500\cdot 4,725 \tag{5.4.91}$$

From this we deduce that:

$$\text{LCM}(1,500;4,725)=\frac{1,500\cdot 4,725}{\text{GCD}(1,500;4,725)}=\frac{7,087,500}{75}=94,500 \tag{5.4.92}$$

We have:

$$1,500=2^2\cdot 3\cdot 5^3 \quad\text{and}\quad 4'725=3^3\cdot 5^2\cdot 7 \tag{5.4.93}$$

If we write the decomposition using the same prime factors for both numbers and allowing the use of zero exponents, we can write:

$$1,500=2^2\cdot 3^1\cdot 5^3\cdot 7^0 \quad\text{and}\quad 4,725=2^0\cdot 3^3\cdot 5^2\cdot 7^1 \tag{5.4.94}$$

We can then observe that the number obtained by taking the smallest exponents is:

$$2^0\cdot 3^1\cdot 5^2\cdot 7^0=75=\text{GCD}(1,500;4,725) \tag{5.4.95}$$

and the number obtained by taking the largest exponents is:

$$2^2\cdot 3^3\cdot 5^3\cdot 7^1=94,500=\text{LCM}(1,500;4,725) \tag{5.4.96}$$

Theorem 5.25. Let a and b be two natural numbers greater than or equal to 2, decomposed in the form:

$$a=p_1^{\alpha_1}p_2^{\alpha_2}\ldots p_k^{\alpha_k} \quad\text{and}\quad b=p_1^{\beta_1}p_2^{\beta_2}\ldots p_k^{\beta_k} \tag{5.4.97}$$

where $p_1,p_2,\ldots,p_k$ are prime numbers, $\alpha_1,\alpha_2,\ldots,\alpha_k$ and $\beta_1,\beta_2,\ldots,\beta_k$ natural numbers, possibly equal to zero.

For each value of i between 1 and k, we define:

$$\delta_i:=\min(\alpha_i,\beta_i) \quad\text{and}\quad \gamma_i:=\max(\alpha_i,\beta_i) \tag{5.4.98}$$

Therefore:

$$\text{GCD}(a;b)=p_1^{\delta_1}p_2^{\delta_2}\ldots p_k^{\delta_k} \quad\text{and}\quad \text{LCM}(a;b)=p_1^{\gamma_1}p_2^{\gamma_2\cdots}p_k^{\gamma k} \tag{5.4.99}$$

Proof 5.25.1. All divisors of a are of the form:

$$d=p_1^{\theta_1}p_2^{\theta_2}\ldots p_k^{\theta_k} \tag{5.4.100}$$

where $\theta_1,\theta_2,\ldots,\theta_k$ are natural numbers such that:

$$0\leq\theta_1\leq\alpha_1,0\leq\theta_2\leq\alpha_2,\ldots,0\leq\theta_k\leq\alpha_k \tag{5.4.101}$$

All divisors of b are of the form:

$$D=p_1^{\sigma_1}p_2^{\sigma_2}\ldots p_k^{\sigma_k} \tag{5.4.102}$$

where $\sigma_1, \sigma_2, \ldots, \sigma_k$ are natural numbers such that:

$$0 \leq \sigma_1 \leq \beta_1, 0 \leq \sigma_2 \leq \beta_2, \ldots, 0 \leq \sigma_k \leq \beta_k \tag{5.4.103}$$

The common divisors of a and b are then of the form:

$$p_1^{\pi_1} p_2^{\pi_2} \ldots p_k^{\pi_k} \tag{5.4.104}$$

where $\pi_1, \pi_2, \ldots, \pi_k$ are natural numbers such that:

$$0 \leq \pi_1 \leq \alpha_1, \quad 0 \leq \pi_2 \leq \alpha_2, \ldots, 0 \leq \pi_k \leq \alpha_k \quad \text{et} \quad 0 \leq \pi_1 \leq \beta_1, 0 \leq \pi_2 \leq \beta_2, \ldots, 0 \leq \pi_k \leq \beta_k \tag{5.4.105}$$

We therefore conclude that:

$$0 \leq \pi_1 \leq \delta_1, \quad 0 \leq \pi_2 \leq \delta_2, \ldots, 0 \leq \pi_k \leq \delta_k \tag{5.4.106}$$

The greatest common divisor (GCD) of a and b is obtained by definition for exponents equal to the largest possible values of π_i, that is, for exponents equal to δ_i. Therefore, we have:

$$\text{GCD}(a;b) = p_1^{\delta_1} p_2^{\delta_2} \ldots p_k^{\delta_k} \tag{5.4.107}$$

Now, the reader may remember that we demonstrated above that:

$$\text{GCD}(a;b) \cdot \text{LCM}(a;b) = a \cdot b \tag{5.4.108}$$

We then have:

$$\text{LCM}(a;b) = \frac{a \cdot b}{\text{GCD}(a;b)} = \frac{p_1^{\alpha_1} p_2^{\alpha_2} \ldots p_k^{\alpha_k} \cdot p_1^{\beta_1} p_2^{\beta_2} \ldots p_k^{\beta_k}}{p_1^{\delta_1} p_2^{\delta_2} \ldots p_k^{\delta_k}} = p_1^{\alpha_1+\beta_1-\delta_1} p_2^{\alpha_2+\beta_2-\delta_2} \ldots p_k^{\alpha_k+\beta_k-\delta_k} \tag{5.4.109}$$

On the other hand, we have:

$$\alpha_i + \beta_i = \min(\alpha_i, \beta_i) + \max(\alpha_i, \beta_i) = \delta_i + \gamma_i \tag{5.4.110}$$

Therefore:

$$\alpha_i + \beta_i - \delta_i = \gamma_i \tag{5.4.111}$$

We therefore conclude:

$$\text{LCM}(a;b) = p_1^{\gamma_1} p_2^{\gamma_2} \ldots p_k^{\gamma_k} \tag{5.4.112}$$

■ Q.E.D.

5.4.3.5 Congruences (modular arithmetic)

Modular arithmetic is a system of arithmetic for integers, where numbers "wrap around" upon reaching a certain value, named the "modulus" (plural moduli).

A familiar use of modular arithmetic is in the 12-hour clock (and also the calendar), in which the day is divided into two 12-hour periods. If the time is 7:00 now, then 8 hours later it will be 3:00. Usual addition would suggest that the later time should be $7+8=15$, but this is not the answer because clock time "wraps around" every 12 hours; in 12-hour time, there is no "15 o'clock". Likewise, if the clock starts at 12:00 (noon) and 21 hours elapse, then the time will be $9:00$ the next day, rather than 33:00. Because the hour number starts over after it reaches 12, this is arithmetic modulo 12. According to the definition below, 12 is congruent not only to 12 itself, but also to 0, so the time "12:00" could also be written "0:00", since 12 is congruent to 0 modulo 12.

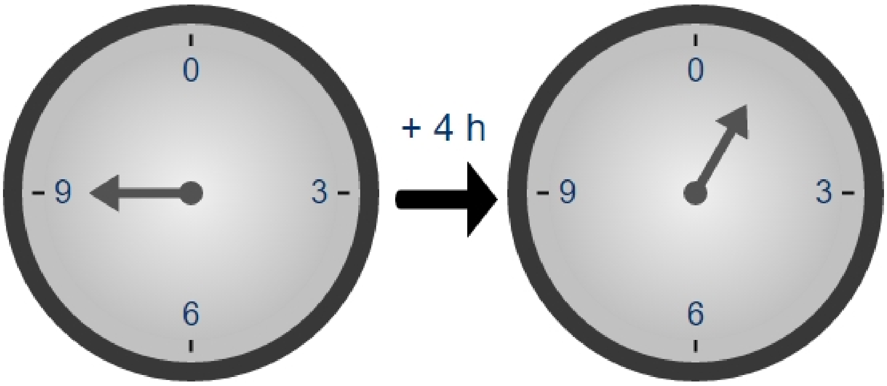


Figure 5.49: Time-keeping on a clock using modulo 12 arithmetics (source: Wikipedia)

Definition (#5.4.68): Let $m \in \mathbb{Z} \setminus 0$. If a and b have the same remainder when divided by m in the Euclidean division then we say "a is congruent to b modulo m", and we write:

$$\boxed{a \equiv b \mod (m)} \tag{5.4.113}$$

or equivalently there is (at least) one relative integer k such that:

$$\boxed{a = b + km} \tag{5.4.114}$$

Often denoted:

$$x = qm + r \tag{5.4.115}$$

where q is the "quotient" and r the "remainder" of the euclidean division.

✍**Example:**

We have:

$$51 \equiv 1 \mod (10)$$

as (we apply $a=b+km$):

$$51 = 1 + 5 \cdot 10$$

And we have:

$$-51 \equiv 9 \mod (10)$$

as (we apply again $a = b + km$):

$$-51 = 9 + (-6) \cdot 10$$

We also name the number b "residue". Thus, a residue is an integer congruent to another, modulo a given integer m. The reader can verify that this requires that:

$$m|(a-b) \tag{5.4.116}$$

The case with negative number is many times difficult to grasp. So let us do a step by step in-deep companion example!

Suppose we try to calculate $-3 \div 12$. A possible answer is:

$$-3 = -1 \cdot 12 + 9$$

In other words, that $-3 \mod 12 = 9$. But can't we represent this as:

$$-3 = -2 \cdot 12 + 21$$

It's true that $-3 \equiv 21 \mod 12$. And also that $-3 \equiv 117 \mod 12$, and of course $-3 \equiv 9 \mod 12$ (or alternatively $-3 \mod 12 = 9$). All of these numbers are in the same "congruence or residue class". Typically the smallest non-negative value is used to represent the class by tradition such that $0 \geq b < m$.

So we could write this congruence class as $\{\ldots, -15, -3, 9, 21, 33, \ldots\}$ but that would become tedious so by convention we represent the congruence class by just one of its members, often the smallest non-negative member. So we represent $\{\ldots, -15, -3, 9, 21, 33, \ldots\}$ by $9 \mod 12$.

✍**Example:**

All spreadsheets and business intelligence softwares have a modulo function often denoted `MOD(value,congruence)` (that returns the b of $a = b + km$) and used for various reasons. But the most used and well known practical case is the calculation of the fiscal month, given the civil month (for example the civil month starts obviously in January (1) but the fiscal month may start for a corporation in April (4). So how can we implement a formula that give the right column in the table below (in the practice you can't generate the column by writing the fiscal months manually because most corporations work on a daily basis and have thousands of days for which they want to know what is the fiscal month!):

	Civil Month (CM)	**Fiscal Month** (FM)
JAN	1	$(-3 \mod 12)+1=9+1=10$
FEB	2	$(-2 \mod 12)+1=10+1=11$
MAR	3	$(-1 \mod 12)+1=11+1=12$
APR	4	$(0 \mod 12)+1=0+1=1$
MAY	5	$(1 \mod 12)+1=1+1=2$
JUN	6	$(2 \mod 12)+1=2+1=3$
JUL	7	$(3 \mod 12)+1=3+1=4$
AUG	8	$(4 \mod 12)+1=4+1=5$
SEP	9	$(5 \mod 12)+1=5+1=6$
OCT	10	$(6 \mod 12)+1=6+1=7$
NOV	11	$(7 \mod 12)+1=7+1=8$
DEC	12	$(8 \mod 12)+1=8+1=9$

In the special case above where the fiscal month is April (4), in all spreadsheet softwares, business intelligence softwares, engineering softwares and programming languages, the formula would be:

```
Fiscal Month = MOD(Civil Month-4,12)+1
```

Or written in more general way:

```
MOD(Civil Month-Fiscal Month Start,12)+1
```

This is equivalent to:

$$a=b+km \Leftrightarrow \texttt{b = MOD(a,m)} \Rightarrow \texttt{FM=MOD(CM-FMS,12)+1}$$

Remarks

R1. The reader must well understand that congruence implies a null remainder for the division!

R2. We exclude in addition to the 0 also the 1 and $-1$for the possible values of m in the definition of congruence in some books.

R3. Behind the term congruence are hidden similar concepts of different levels of abstraction:

- In modular arithmetic, so we say that "two integers a and b are congruent modulo m if they have the same remaining in the Euclidean division by m". We can also say that they are congruent modulo m if their difference is a multiple of m.

- In the study of oriented angles, we say that "two measurements are congruent modulo 2π [rad] if and only if their difference is a multiple of 2π [rad]". This characterize two measures of the same angle (see section Trigonometry page 2513).

- In algebra, we speak of congruence modulo I in a commutative ring (see section Set Theory page 426) for which I is an ideal: "x is congruent to y modulo I

if and only if their difference belongs to I". This congruence is an equivalence relation compatible with the operations of addition and multiplication and gives the possibility to define a quotient ring of the parent set with its ideal I.

- We sometimes see in the study of geometry (see section Euclidean Geometry page 2633) the term "congruence" used in place of "similar". It is then a simple equivalence relation on the set of plane figures.

The relation of congruence $\equiv$ is an equivalence relation (see section Operators page 290), in other words, given $a, b, c, m \in \mathbb{Z}, m > 1$ then the congruence relation is:

P1. Reflexive:

$$a \equiv a \mod (m) \tag{5.4.117}$$

P2. Symmetric:

$$a \equiv b \mod (m) \Leftrightarrow b \equiv b \mod (m) \tag{5.4.118}$$

P3. Transitive:

$$a \equiv b \mod (m), b \equiv c \mod (m) \Rightarrow a \equiv b \mod (m) \tag{5.4.119}$$

The properties P1 and P2 are obvious (if this is not the case please let us know we will develop!). We will prove only P3.

Proof 5.25.2. The assumptions imply that:

$$b = a + km \qquad c = b + lm \tag{5.4.120}$$

But then:

$$c = b + lm = (a + km) + lm = a + (k + l)m \tag{5.4.121}$$

This proves that a and c are congruent modulo m.

■ Q.E.D.

The relation of congruence $\equiv$ is compatible with the sum and the product (remember that power is ultimately an extension of the product!).

Indeed, given $(a, b, a', b', m) \in \mathbb{Z}, m > 1$ such that $a \equiv \mod (m)$ and $a' \equiv b'$ then:

P1. $a + a' \equiv b + b' \mod (m)$

P2. $aa' \equiv bb' \mod (m)$

Proof 5.25.3. We have:

$$a = b + km \qquad a' = b' + lm \tag{5.4.122}$$

by hypothesis. But then:

$$a + a' = b + b' + (l + k)m \tag{5.4.123}$$

which proves P1. We also have:

$$aa' = bb' + blm + b'km + klm'2 = bb' + sm \tag{5.4.124}$$

which proves P2.

■ Q.E.D.

Remark

The congruence relation behaves in many point like the relation of equality. However a property of the relation of equality $=$ is not true for that of congruence $\equiv$, namely the simplification: If $ab \equiv \mod (m)$, we do not have necessarily $b \equiv c \mod (m)$.

✍**Examples:**

E1. Consider the following simple case:

$$2 \cdot 1 \equiv 2 \cdot 3 \mod (4) \quad \text{but} \quad 1 \not\equiv 3 \mod (4) \tag{5.4.125}$$

E2. Gangsters have just stolen a million dollars, in denominations of $1, 10, 100$ and $1,000$ dollars. One of them claims that there are exactly $92,000$ in bills. Is this statement correct?

According to the gangster's statement, the stolen amount is written as:

$$1'000'000 = a + 10b + 100c + 1'000d$$

where:

$$a + b + c + d = 92,000$$

Modulo 9 (this is a good choice!), this gives:

$$1 \equiv a + b + c + d$$

hence:

$$1 \equiv 2$$

Therefore we have the proof of the gangster's dishonesty (but that was something we suspected).

So far we have seen the properties of congruences involving a single modulus. We will now study the behaviour of the congruence relation on a change of modulus:

P1. If $a \equiv b \mod (m)$ and $d|m$, then $a \equiv b \mod (d)$

P2. If $a \equiv b$ and $a \equiv b \mod (s)$ then a and b are congruate modulus $[r, s]$

We think this two properties are obvious. We do not need to go into details for P1. For P2, since $b - a$ is a multiple of r and s since by hypothesis:

$$\frac{b-a}{r} = k, \frac{b-a}{s} = l \Rightarrow b - a = rk = sl \qquad (5.4.126)$$

$b - a$ is then a multiple of the LCM of r and s, which proves P2.

From these properties it follows that if we denote by $f(x)$ a polynomial with integer coefficients (positive or negative):

$$f(x) = Ax^n + Bx^{n-1} + Cx^{n-2} + \ldots + Kx + L \qquad (5.4.127)$$

The congruence $a \equiv b \mod (m)$ will also give $f(a) \equiv f(b) \mod (m)$.

If we replace x successively by all integers in a polynomial $f(x)$ with integer coefficients, and if we take the remaining modulus m, these remaining are reproduced from m to m (in the sense where the congruence is satisfied), since we have, regardless of the number m and x:

$$f(x) \equiv f(x+m) \mod (m) \qquad (5.4.128)$$

We then deduce then the impossibility of solving the following congruence:

$$f(x) \equiv r \mod (m) \qquad (5.4.129)$$

with integer numbers, if r is anyone of the "non-remaining" (a residue that does not satisfy the congruence).

5.4.3.5.1 Congruence Class

Definition (#5.4.69): We name "modulo m congruence class", the subset of the set $\mathbb{Z}$ defined by the property that two elements a and b of $\mathbb{Z}$ are in the same class if and only if $a \equiv b \mod (m)$ or that a set of elements are congruent by this same modulo.

Remark

We saw in the section Operators that this is in fact an equivalence class (page 292) as the congruence modulo m is, as we have proved above, a relation of equivalence!!!

✍**Example:**

Given $m = 3$. We divide the set of integers into congruence classes of modulo 3. Here are for example three sets whose elements are congruent with one another without rest (see well what gives the set of all these classes together!):

$$\begin{gathered}\{\ldots,-9,-6-3,0,3,6,9,12,\ldots\}\\ \{\ldots,-8,-5,-2,1,4,7,10,13,\ldots\}\\ \{\ldots,-7,-4,-1,2,5,8,11,\ldots\}\end{gathered} \tag{5.4.130}$$

Thus we see that for each pair of elements of a congruence class, the congruence modulo 3 exists. However, we see that we can not take that $-9 \equiv -8 \mod (3)$ where -9 is in the first class and -8 in the second.

The smallest non-negative number of the first class is 0, this of the second is 1 and the last is 2. Thus, we will denote these three classes respectively $[0]_3$, $[1]_3$, $[2]_3$, the number 3 in the index indicating the modulus.

It is interesting to notice that if we take any number of the first class and any number of the second class, then their sum is always in the second class. This can be generalized and allows to define a sum of classes modulo 3 by writing:

$$\begin{gathered}[0]_3+[0]_3=[0]_3;\quad [0]_3+[1]_3=[1]_3\\ [0]_3+[2]_3=[2]_3;\quad [1]_3+[1]_3=[2]_3\\ [1]_3+[2]_3=[0]_3;\quad [2]_3+[2]_3=[1]_3\end{gathered} \tag{5.4.131}$$

and also:

$$\begin{gathered}[0]_3\times[0]_3=[0]_3;\quad [0]_3\times[1]_3=[0]_3\\ [0]_3\times[2]_3=[0]_3;\quad [1]_3\times[1]_3=[1]_3\\ [1]_3\times[2]_3=[2]_3;\quad [2]_3\times[2]_3=[1]_3\end{gathered} \tag{5.4.132}$$

Thus, for any $m > 1$, the congruence class:

$$a \mod (m) \tag{5.4.133}$$

is the set of integers congruent to a modulo m (and congruent modulo m between them)!!! This class is denoted by:

$$\boxed{[a]_m := a \mod (m)} \tag{5.4.134}$$

Remark

Having bracketed the expression "and congruent modulo m between them" is due to the fact that the congruence, being an equivalence relation we have as we have proved above that $b \equiv a \mod (m)$, $c \equiv \mod (m)$, then $b \equiv a \mod (m)$.

Definition (#5.4.70): The set of congruence classes $[a]_m$ (that forms by the fact that congruence is an equivalence relation: "equivalence classes"), for a fixed m gives what we name a "quotient set" (see section Operators page 292). More rigorously, we speak of the "quotient set of $\mathbb{Z}$ by the congruence relation" whose elements are the congruence classes (or: equivalence classes) and then form the ring $\mathbb{Z}/m\mathbb{Z}$.

We deduce from the definition the following two trivial properties:

1. The number b is in the class $[a]_m$ if and only if $a \equiv b \mod (m)$
2. The classes $[a]_m$ and $[b]_m$ are equal if and only if $a \equiv b \mod (m)$

Theorem 5.26. There are exactly m different congruence classes of modulo m, i.e. $[0]_m, [1]_m, \ldots, [m-1]_m$.

Proof 5.26.1. Given $m > 1$, than any integer a is congruent modulo m to one and only one integer r of the set $\{0, 1, 2, \ldots, m-1\}$ (notice well, it is important, that we restrict ourselves to the positive integers without taking into account the negative one!). In addition, this integer r is exactly the remaining of the division of a by m. In other words, if $0 \leq r < m$, then:

$$a \equiv r \mod (m) \tag{5.4.135}$$

if and only if $a = qm + r$ where q is the quotient of a by m and r is the remainder. The proof is an immediate consequence of the definition of the congruence and of the Euclidean division.

■ Q.E.D.

Definition (#5.4.71): An integer b in a congruence class modulo m is named a "representative of this class" (it is clear that by the equivalence relation that two representative of the same class are congruent modulo m to each other).

We can now be able to build an addition and a multiplication on the congruence classes. To define the sum of two classes $[a]_m, [b]_m$, it suffices to take one representative from each class, to their sum and take the congruence class of the result. Thus (see examples above):

$$[a]_m + [b]_m = [a + b]_m \tag{5.4.136}$$

And same for the multiplication:

$$[a]_m \cdot [b]_m = [a \cdot b]_m \tag{5.4.137}$$

By construction of the addition and multiplication, we see that 0 (zero) is the neutral element for addition:

$$[a]_m + [0]_m = [a]_m, \quad \forall a \in \mathbb{Z}, \forall m \in \mathbb{N} \tag{5.4.138}$$

and the class of the integer 1 is the neutral element for multiplication:

$$[a]_m \cdot [1]_m = [a]_m, \quad \forall a \in \mathbb{Z}, \forall m \in \mathbb{N} \tag{5.4.139}$$

Definition (#5.4.72): An element $[a]_m$ of $\mathbb{Z}/m\mathbb{Z}$ is "one unit" if there is an element $[b]_m \in \mathbb{Z}/m\mathbb{Z}$ such that $[a]_m \cdot [b]_m$. The following theorem helps to characterize classes modulo m which are units in $\mathbb{Z}/m/\mathbb{Z}$:

Theorem 5.27. Given $[a]$ an element of $\mathbb{Z}/m/\mathbb{Z}$. Then $[a]$ is a unit if and only if $(a, m) = 1$.

Proof 5.27.1. Suppose first that $(a, m) = 1$. Then by Bézout's theorem, we have its identity:

$$as + mr = 1 \tag{5.4.140}$$

In other words, as is congruent to 1 modulo m. But this is equivalent to write by definition that $[a][s] = 1$ showing that $[a]$ is a unit. Conversely, if $[a]$ is a unit, this implies that there exists a class $[s]$ such that $[a][s] = 1$.

Thus, we have just proved that $\mathbb{Z}/\mathbb{Z}$ is indeed a ring since it has an addition, a multiplication, a neutral element and an inverse!!

■ Q.E.D.

5.4.3.5.2 Complete set of residues

Definition (#5.4.73): A set of numbers $a_0, a_1, \ldots, a_{(m-1)} \mod (m)$ form a "complete set of residues", also named a "covering system", if they satisfy $a_i = i \mod (m)$ for $i = 0, 1, \ldots, m-1$.

This type of systems will help us to introduce in the section of Cryptography (page 7216) an important function used to secured communication devices at the end of the 120th century (holocene calendar) and at beginning of the 121st century.

To introduce this concept, consider the following finite system of congruences modulo 6:

$$\begin{aligned} 6 &\equiv 0 \mod (6)\\ 13 &\equiv 1 \mod (6)\\ 2 &\equiv 2 \mod (6)\\ -3 &\equiv 3 \mod (6)\\ 22 &\equiv 4 \mod (6)\\ 11 &\equiv 5 \mod (6) \end{aligned} \tag{5.4.141}$$

where as the reader will have probably noticed it: no residue is repeated in the list and no residue taken in pairs are congruent between them modulo m (is this last point that oblige to stop at 5 in our example). We then say that the residues are "mutually incongruent".

If these conditions are met, then we say that the ordered set $\{6, 13, 2, -3, 22, 11\}$ is a "complete system of residues modulo m" as already defined. Such a set is not unique for a given module. Thus, the set $\{0, 1, 2, 3, 4, 5\}$ is also a complete (trivial) system of residues modulo 6.

If we eliminate from this entire system all numbers that are not prime to m, then we have a "system of reduced residue modulo m". So in the above example, the reduced residue system modulo 6 will be $\{13, 11\}$.

Reduces systems will be useful to us in the section Cryptography (page 7216) to prove an important result in the asymmetric public key systems.

We will see also in the section Cryptography (page 7236), the "Euler indicator function" when m is prime (which is not the case in the previous example) gives the cardinal of the reduced system modulus m as being equal to:

$$\boxed{\phi(m) = m - 1 = \text{Card}\left(\{n \leq m, (n, m) = 1\}\right)} \tag{5.4.142}$$

So under the assumption condition that m is prime, the reduced system of residue is obviously written:

$$\{r_1, r_2, \ldots, r_\phi(m)\} \tag{5.4.143}$$

5.4.3.5.3 Chinese remainder theorem

In its basic form, the Chinese remainder theorem will determine a number n that, when divided by some given divisors, leaves given remainders. In Sun Tzu's example (stated in modern terminology), what is the smallest number n that when divided by 3 leaves a remainder of 2, when divided by 5 leaves a remainder of 3, and when divided by 7 leaves a remainder of 2?

The Chinese remainder theorem can therefore be seen as solving a linear system but in a modular system. For many students and future engineers, this theorem will never be used in practice, but some will see it again it in the field of cryptography (in the context of decryption especially).

There are several possible proofs as always but we opted for the one that, as always for us, seemed the most educational.

Given m and n both prime integers between them. Then special case of a system of two congruences (see further below for an example of resolution of a system of three congruences):

$$\begin{aligned} x &\equiv a \mod (m)\\ x &\equiv b \mod (m) \end{aligned} \tag{5.4.144}$$

has a unique solution.

Proof 5.27.2. As m and n are assumed as prime between them, there exists then u and v two integers such as (application of the Bézout identity proved earlier above):

$$um+vn=1 \tag{5.4.145}$$

Therefore we have:

$$aum+avn=a \tag{5.4.146}$$

That is to say:

$$avn\equiv a \mod (m) \tag{5.4.147}$$

Then we have also by extension:

$$bum+bvn=b \tag{5.4.148}$$

That is to say:

$$bum\equiv b \mod (n) \tag{5.4.149}$$

So to be clear, we have so far:

$$um+vn=1 \Rightarrow \begin{cases} avn\equiv a \mod (m)\\ bum\equiv b \mod (n) \end{cases} \tag{5.4.150}$$

We then have for recall:

$$bum\equiv b \mod (n) \Rightarrow bum+bvn=b \tag{5.4.151}$$

But we can also write with $k \in \mathbb{Z}$:

$$bum + \underbrace{(k + av)}_{=bv} n = b \tag{5.4.152}$$

Therefore:

$$bum + avn \equiv b \mod (n) \tag{5.4.153}$$

Then we also have:

$$avn \equiv a \mod (m) \Rightarrow\Rightarrow aum + avn = a \tag{5.4.154}$$

But we can also write with $k \in \mathbb{Z}$:

$$\underbrace{(K + bu)}_{=au} m + avn = a \tag{5.4.155}$$

Therefore:

$$bum + avn \equiv a \mod (m) \tag{5.4.156}$$

So to be always clear, we have so far:

$$\begin{aligned} um + vn = 1 = (m, n) &\Rightarrow \begin{cases} avn \equiv a \mod (m) \\ bum \equiv b \mod (n) \end{cases} \\ &\Rightarrow \begin{cases} bum + avn \equiv a \mod (m) \\ bum + avn \equiv b \mod (n) \end{cases} \end{aligned} \tag{5.4.157}$$

So finally we get that:

$$x = bum + avn \tag{5.4.158}$$

is a particular solution of the system. But we also have $\forall i, j \in \mathbb{Z}$ by the definition of the congruence:

$$\begin{aligned} bum + avn + im \equiv a \mod (m) \\ bum + avn + jn \equiv b \mod (n) \end{aligned} \tag{5.4.159}$$

So that x is always solution of the system, we must have:

$$\begin{aligned} i = n \\ j = m \end{aligned} \tag{5.4.160}$$

and therefore:

$$\begin{aligned} bum + avn + nm \equiv a \mod (m) \\ bum + avn + mn \equiv b \mod (n) \end{aligned} \tag{5.4.161}$$

Therefore a little bit more general solution is:

$$x = bum + avn + nm \tag{5.4.162}$$

But by extension, we have the general solution:

$$x = bum + avn + znm \tag{5.4.163}$$

with $z \in \mathbb{Z}$. We then say sometimes that the solution is "x modulo nm".

■ Q.E.D.

✍**Example:**

As an example, consider the problem of finding an integer x such that:

$$\begin{aligned} x &\equiv 2 \mod (3) \\ x &\equiv 3 \mod (4) \\ x &\equiv 1 \mod (3) \end{aligned} \tag{5.4.164}$$

A brute-force approach converts these congruences into sets and writes the elements out to the product of $3 \cdot 4 \cdot 5 = 60$ (the solutions modulo 60 for each congruence):

$$\begin{aligned} &x \in \{2, 5, 8, \mathbf{11}, 14, 17, 20, 23, 26, 29, 32, 35, 38, 41, 44, 47, 50, 53, 56, 59\} \\ &x \in \{3, 7, \mathbf{11}, 15, 19, 23, 27, 31, 35, 39, 43, 47, 51, 55, 59\} \\ &x \in \{1, 6, \mathbf{11}, 16, 21, 26, 31, 36, 41, 46, 51, 56\} \end{aligned} \tag{5.4.165}$$

To find an x that satisfies all three congruences, intersect the three sets to get:

$$x = 11 \tag{5.4.166}$$

This solution is modulo 60, hence all solutions are expressed as:

$$x \equiv 11 \mod (60) \tag{5.4.167}$$

Another way to find a solution is with basic algebra, modular arithmetic, and stepwise substitution.

We start by translating these congruences into equations for some t, s, and u:

$$\begin{aligned} x &= 2 + 3t \\ x &= 3 + 4s \\ x &= 1 + 5u \end{aligned} \tag{5.4.168}$$

After we substitute the x from the first equation into the second congruence:

$$2 + 3t \equiv 3 \mod (4) \tag{5.4.169}$$

That is to say:

$$3t \equiv 1 \mod (4) \tag{5.4.170}$$

Hence:

$$t \equiv 3 \mod (4) \tag{5.4.171}$$

meaning that $t = 3 + 4s$ for some integer s. Substitute now t into the first equation:

$$x = 2 + 3t = 2 + 3(3 + 4s) = 11 + 12s \tag{5.4.172}$$

Substitute this x into the third congruence:

$$11+12s \equiv 1 \mod (5) \tag{5.4.173}$$

That is to say:

$$1+1s \equiv 1 \mod (5) \tag{5.4.174}$$

Hence:

$$2s \equiv 0 \mod (5) \tag{5.4.175}$$

meaning that $s=0+5u$ for some integer u. Finally:

$$x=11+12s=11+12(5u)=11+60u \tag{5.4.176}$$

So, we have solution $\{11,71,131,191,\ldots\}$.

5.4.3.6 Continued fractions

Definition (#5.4.74): A "continued fraction" is an expression obtained through an iterative process of representing a number as the sum of its integer part and the reciprocal of another number, then writing this other number as the sum of its integer part and another reciprocal, and so on. In a finite continued fraction (or terminated continued fraction), the iteration/recursion is terminated after finitely many steps by using an integer in lieu of another continued fraction. In contrast, an infinite continued fraction is an infinite expression. In either case, all integers in the sequence, other than the first, must be positive. The integers a_i are named the "coefficients" or "terms" of the continued fraction.

The notion of continued fraction come back from the time of Fermat and culminated with the work of Lagrange and Legendre in the late 118th century (holocene calendar). These fractions are important in physics because we find them back in our study of acoustic and also in the thought process that led Galois to develop his group theory and also in the studies of gear ratios (for watch complications as discussed in the section of Mechanical Engineering page 8368). Continued fractions will also be very useful to us in the section of Astronomy to determine the saros cycles of lunar and solar eclipses (see page 5486).

To understand the motivation of continued fraction let us introduce a basic example.

Consider a typical rational number:

$$\frac{415}{93} \tag{5.4.177}$$

which is around 4.4624.

As first approximation, start with 4, which is the integer part:

$$\frac{415}{93}=4+\frac{43}{93} \tag{5.4.178}$$

Note that the fractional part is the reciprocal of $93/43$ which is about 2.1628. Use the integer part, 2, as an approximation for the reciprocal, to get a second approximation of:

$$\frac{93}{43}=2+\frac{7}{43} \tag{5.4.179}$$

So we have so far:

$$\frac{415}{93}=4+\cfrac{1}{2+\cfrac{7}{43}} \tag{5.4.180}$$

Note that the fractional part is the reciprocal of $43/7$ which is about 6.1429. Use the integer part, 6, as an approximation for the reciprocal, to get a second approximation of:

$$\frac{43}{7}=6+\frac{1}{7} \tag{5.4.181}$$

Therefore:

$$\frac{415}{93}=4+\cfrac{1}{2+\cfrac{1}{6+\cfrac{1}{7}}} \tag{5.4.182}$$

Note that the fractional part $1/7$ is the reciprocal of 7 which is about... 7 Use the integer part, 7, as an approximation for the reciprocal, to get a second approximation of:

$$\frac{7}{1}=7+\frac{0}{1} \tag{5.4.183}$$

Therefore we get:

$$\frac{415}{93}=4+\cfrac{1}{2+\cfrac{1}{6+\cfrac{1}{7+\cfrac{0}{1}}}}=4+\cfrac{1}{2+\cfrac{1}{6+\cfrac{1}{7}}} \tag{5.4.184}$$

This expression is named as we know the "continued fraction representation of the number".

Dropping some of the less essential parts of the expression:

$$\frac{415}{93}=4+\cfrac{1}{2+\cfrac{1}{6+\cfrac{1}{7}}} \tag{5.4.185}$$

gives the abbreviated notation:

$$\frac{415}{93}=[4;2,6,7] \tag{5.4.186}$$

Note that it is customary to replace only the first comma by a semicolon.

As generalization of the previous example let us consider in a first time the rational number a/b with $(a,b)=1$ with $b>0$ and $a>b$. We know that all the quotients q_i and the remaining r_i are within the scope of the Euclidean division positive integers.

Let us recall that the Euclidean algorithm already seen earlier (but written in a slightly different way):

$$\begin{aligned}\frac{a}{b}&=q_1+\frac{r_1}{b}\\\frac{b}{r_1}&=q_2+\frac{r_2}{r_1}\\\frac{r_1}{r_2}&=q_3+\frac{r_3}{r_2}\\&\ldots\\\frac{r_{n-2}}{r_{n-1}}&=q_n\end{aligned}\tag{5.4.187}$$

By successive substitutions, we get:

$$\begin{aligned}\frac{a}{b}&=q_1+\frac{1}{b/r_1}=q_1+\cfrac{1}{q_2+\cfrac{1}{r_1/r_2}}\\&=\ldots\\&=q_1+\cfrac{1}{q_2+\cfrac{1}{q_3+\cfrac{1}{\ddots\cfrac{}{\cfrac{1}{q_{n_1}+\cfrac{1}{q_n}}}}}}\end{aligned}\tag{5.4.188}$$

What is also sometimes written:

$$\frac{a}{b}=q_1+\frac{1}{1/\varepsilon_1}=q_1+\cfrac{1}{q_2+\cfrac{1}{\varepsilon_2}=\ldots}\tag{5.4.189}$$

So any positive rational number can be expressed as a finite continued fraction where $q_n\in\mathbb{N}$.

Taking our introducing example:

$$\frac{415}{93}=4+\cfrac{1}{2+\cfrac{1}{6+\cfrac{1}{7+\cfrac{0}{1}}}}=4+\cfrac{1}{2+\cfrac{1}{6+\cfrac{1}{7}}}\tag{5.4.190}$$

we notice indeed that $q_n\in\mathbb{N}$ and that we have by construction:

$$q_n=\left[\frac{1}{\varepsilon_{n-1}}\right]\tag{5.4.191}$$

where the brackets represent the integer part and that we also have:

$$\frac{1}{\varepsilon_{n_1}}=q_n+\varepsilon\tag{5.4.192}$$

The development of the number a/b is named the "development of the number a/b in finite continued fraction" and is condensed in the following notation:

$$\boxed{[q_1; q_2, q_3, \ldots, q_n]} \tag{5.4.193}$$

Let us see now another example:

✍**Example:**

Let us see how the extract the square root of a number A (for example $A = 2$ such that we want to extract $\sqrt{2}$) by the continued fraction method.

Given a the largest integer whose square a^2 is smaller than A. We subtract it to A. So there is a remaining of (for $A = 2$, we have $a = 1$):

$$r = A - a^2 = (\sqrt{A} - a)(\sqrt{A} + a) \tag{5.4.194}$$

where we have used a remarkable identities that we will prove in the section Calculus later (page 1361). Hence dividing both members by the second parenthesis, we have:

$$\sqrt{A} - a = \frac{r}{\sqrt{A} + a} \tag{5.4.195}$$

Therefore:

$$\sqrt{A} = a + \frac{r}{\sqrt{A} + a} \tag{5.4.196}$$

In the denominator, we replace $\sqrt{A}$ by:

$$a + \frac{r}{\sqrt{A} + a} \tag{5.4.197}$$

That gives:

$$\sqrt{A} = a + \cfrac{r}{2a + \cfrac{r}{\sqrt{A} + a}} \tag{5.4.198}$$

etc... we thus see that the system is simple to determine the expression of a root square in terms of continued fraction.

We consider now as intuitive that every rational number can be expressed as finite continued fraction and conversely that any finite continued fraction represents a rational number. By extension, an irrational number is represented by an infinite continued fraction!

Now consider $[q_1; q_2, q_3, \ldots, q_n]$ a finite continued fraction. The continued fraction:

$$C_k = [q_1; q_2, \ldots, q_n] \tag{5.4.199}$$

where $k = 1, 2, \ldots, n$ is named the "k-th reduced" or "k-th convergent" or the "k-th partial quotient".

With this notation, we have:

$$\begin{aligned} C_1 &= [q_1] = q_1 \\ C_2 &= [q_1; q_2] = q_1 + \frac{1}{q_2} = \frac{q_1 q_2 + 1}{q_2} \\ C_3 &= [q_1; q_2, q_3] = q_1 + \cfrac{1}{q_2 + \cfrac{1}{q_3}} = \frac{(q_1 q_2 + 1) \cdot q_3 + q_1}{q_2 q_3 + 1} \\ C_4 &= [q_1; q_2, q_3, q_4] = \frac{((q_1 q_2 + 1) \cdot q_3 + q_1) \cdot q_4 + (q_1 q_2 + 1)}{(q_2 q_3 + 1) \cdot q_4 + q_2} \end{aligned} \tag{5.4.200}$$

To simplify the expressions above, we introduce the sequences $\{n_i\}, \{d_i\}$ (n is for **n**umerator and d for **d**enominator) defined by:

$$\begin{aligned} n_0 &= 1 \qquad n_1 = q_1, \ldots \qquad n_i = q_i n_{i-1} + n_{i-2} \\ d_0 &= 0 \qquad d_1 = 1, \ldots \qquad d_i = q_i d_{i-1} + d_{i-2} \end{aligned} \tag{5.4.201}$$

Thanks to this construction, we have an interesting immediate little inequality that will be useful to us further below:

$$0 = d_0 < d_1 < d_2 < d_3 < \ldots \tag{5.4.202}$$

With the above definition, we find that:

$$C_1 = \frac{n_1}{d_1}, \quad C_2 = \frac{n_2}{d_2}, \quad C_3 = \frac{n_3}{d_3}, \quad \ldots, \quad C_i = \frac{n_i}{d_i} \tag{5.4.203}$$

Either by generalizing:

$$C_k = [q_1, q_2, q_3, \ldots, q_k] = \frac{n_k}{d_k} \tag{5.4.204}$$

Now let us show for later use that for $i \geq 1$, we have:

$$n_i d_{i-1} - d_i n_{i-1} = (-1)^i \tag{5.4.205}$$

The result is immediate for $i = 1$. Assuming that the result is true for i let us show that it is true for $i + 1$. Since:

$$n_{i+1} d_i - d_{i+1} n_i = (q_{i+1} n_i + n_{i-1}) d_i - (q_{i+1} d_i + d_{i-1}) n_i = -(d_{i-1} n_i - n_{i-1} d_i) = (-1)^{i+1} \tag{5.4.206}$$

then using the induction hypothesis, we get the result!

We can now establish a vital relation for what will follow.

Theorem 5.28. Let us prove that if C_k is the k-th reduced to of the simple finite continued fraction $[q_1; q_2, \ldots, q_n]$ then:

$$C_1 < C_3 < C_5 < \ldots < C_6 < C_4 < C_2 \tag{5.4.207}$$

Proof 5.28.1.

$$\begin{aligned}C_{k+2}-C_k&=(C_{k+2}-C_{k+1})+(C_{k+1}-C_k)=\left(\frac{n_{k+2}}{d_{k+2}}-\frac{n_{k+1}}{d_{k+1}}\right)+\left(\frac{n_{k+1}}{d_{k+1}}-\frac{n_k}{d_k}\right)\\&=\left(\frac{n_{k+2}d_{k+1}-n_{k+1}d_{k+2}}{d_{k+2}d_{k+1}}\right)+\left(\frac{n_{k+1}d_k-n_kd_{k+1}}{d_{k+1}d_k}\right)=\frac{(-1)^{k+2}}{d_{k+2}d_{k+1}}+\frac{(-1)^{k+1}}{d_{k+1}d_k}\\&=\frac{(-1)^{k+2}d_k+(-1)^{k+1}d_{k+2}}{d_{k+2}d_{k+1}d_k}=\frac{(-1)^{k+1}(-1)d_k+(-1)^{k+1}d_{k+2}}{d_{k+2}d_{k+1}d_k}\\&=\frac{-(-1)^{k+1}d_k+(-1)^{k+1}d_{k+2}}{d_{k+2}d_{k+1}d_k}=\frac{(-1)^{k+1}(d_{k+2}-d_k)}{d_{k+2}d_{k+1}d_k}\end{aligned} \tag{5.4.208}$$

as:

$$0=d_0<d_1<d_2<d_3<\ldots \tag{5.4.209}$$

therefore:

$$d_{k+2}-d_k>0 \tag{5.4.210}$$

indicating to us that the sign of $C_{k+1}-C_k$ is the same as $(-1)^{k+1}$.

It follows that $C_{k+2}>C_k$ for an odd k, and $C_{k+2}<C_k$ for k even. Then:

$$C_1<C_3<C_5<\ldots \quad \text{and} \quad C_2>C_4>C_6>\ldots \tag{5.4.211}$$

and after as:

$$C_k-C_{k-1}=\frac{n_k}{d_k}-\frac{n_{k-1}}{d_{k-1}}=\frac{n_kd_{k-1}-n_{k-1}d_k}{d_kd_{k-1}}=\frac{(-1)^k}{d_kd_{k-1}} \tag{5.4.212}$$

So for k even, we have $C_k>C_{k-1}$, we therefore deduce that:

$$C_1<C_3<C_5<\ldots<C_6<C_4<C_2 \tag{5.4.213}$$

■ Q.E.D.

Let us show now that every infinite continued fraction can be any irrational number.

In formal terms, if $\{q_n\}$ is a sequence of positive integers and that we consider $C_n=[q_1;q_2,\ldots,q_n]$ then it necessarily converges to a real number if $n\rightarrow+\infty$.

Actually it is not difficult to observe (it's quite intuitive) with a practical example that we have:

$$C_k-C_{k-1}\rightarrow 0 \tag{5.4.214}$$

when $k\rightarrow+\infty$.

Now, let us denote by x any real number and $q_1=[x]$ the integer part of this real number. Then we saw at the beginning of our study of continued fractions that:

$$x=q_1+\varepsilon_1 \tag{5.4.215}$$

Therefore it comes:

$$\varepsilon_1 = x - q_1 \tag{5.4.216}$$

Let's look for the needs of the section on Acoustics (page 8195) on the calculation of a continued fraction of a logarithm using the previous relation!

First let us recall that:

$$\frac{a}{b} = q_1 + \frac{1}{1/\varepsilon_1} = q_1 + \frac{1}{q_2 + 1/\varepsilon_2} = \ldots \tag{5.4.217}$$

That is (relation proved in the section of Functional Analysis page 2284):

$$x = \log_a(u) = \frac{\ln(u)}{\ln(a)} \tag{5.4.218}$$

with $1 < a < u$ and $(a, u) = 1$.

Given y_n defined by:

$$y_{-1} = u \quad y_0 = a \quad y_{n+1} = \frac{y_{n-1}}{y_n^{q_1}} \tag{5.4.219}$$

Therefore let us prove that:

$$\varepsilon_n = \frac{\ln(y_{n-2})}{\ln(y_{n-1})} - q_n \tag{5.4.220}$$

Indeed for $n = 1$ we have:

$$\varepsilon_1 = x - q_1 = \frac{\ln(u)}{\ln(a)} - q_1 = \frac{\ln(y_{-1})}{\ln(y_0)} - q_1 \tag{5.4.221}$$

for $n = 2$ we use first the fact that:

$$\begin{aligned}\varepsilon_1 = x - q_1 = \frac{\ln(u)}{\ln(a)} - q_1 &= \frac{\ln(u) - q_1\ln(a)}{\ln(a)} = \frac{\ln(u) - \ln(a^{q_1})}{\ln(a)} \\ = \frac{\ln\left(\dfrac{u}{a^{q_1}}\right)}{\ln(a)} &= \frac{\ln\left(\dfrac{y_{-1}}{y_0^{q_1}}\right)}{\ln(a)} = \frac{\ln(y_1)}{\ln(a)}\end{aligned} \tag{5.4.222}$$

Therefore:

$$\frac{1}{\varepsilon_1} = \frac{\ln(a)}{\ln(y_1)} \tag{5.4.223}$$

and as we had proved that:

$$\frac{1}{\varepsilon_{n-1}} = q_n + \varepsilon_n \Rightarrow \varepsilon_2 = \frac{1}{\varepsilon_1} - q_2 = \frac{\ln(a)}{\ln(y_1)} - q_2 = \frac{\ln(y_0)}{\ln(y_1)} - q_2 \tag{5.4.224}$$

etc... by induction demonstrating our right to use this notation changes.

✍**Example:**

Let us look for the expression of the continuous fraction of:

$$x=\log_a(u)=\log_2(3) \tag{5.4.225}$$

We know by playing with the definition of the logarithm that:

$$2^1<3<2^2 \tag{5.4.226}$$

therefore:

$$\begin{aligned}&\log_2(2^1)<\log_2(3)<\log_2(2^2)\Rightarrow\log_2(2)<\log_2(3)<2\log_2(2)\\&\Rightarrow 1<\dfrac{\log_2(3)}{\log_2(2)}<2\Rightarrow 1<\log_2(3)<2\end{aligned} \tag{5.4.227}$$

therefore $q_1=1$. Then we have:

$$\varepsilon_1=\dfrac{\ln(y_{1-2})}{\ln(y_{1_1})}-q_1=\dfrac{\ln(y_{-1})}{\ln(y_0)}-q_1 \tag{5.4.228}$$

and as:

$$y_{-1}=u=3\qquad y_0=a=2 \tag{5.4.229}$$

it comes:

$$\varepsilon_1=\dfrac{\ln(3)}{\ln(2)}-1 \tag{5.4.230}$$

So we have the first partial quotient:

$$\dfrac{a}{b}=\log_2(3)=q_1+\dfrac{1}{1/\varepsilon_1}=1+\dfrac{1}{\dfrac{1}{\frac{\ln(3)}{\ln(2)}-1}}=\ldots \tag{5.4.231}$$

Verbatim we have already:

$$y_{0+1}=y_1=\dfrac{y_{-1}}{y_0^{q_1}}=\dfrac{3}{2^1}=\dfrac{3}{2} \tag{5.4.232}$$

Let us simplify:

$$\left(\dfrac{\ln(3)}{\ln(2)}-1\right)^{-1}=\dfrac{\ln(2)}{\ln\left(\frac{3}{2}\right)}=\dfrac{\ln(2)}{\ln(y_1)} \tag{5.4.233}$$

So the first partial quotient can be written:

$$\log_2(3)=1+\dfrac{1}{\dfrac{\ln(2)}{\ln(y_1)}}=\ldots \tag{5.4.234}$$

and let us go to the second partial quotient. We already know for this that:

$$1<\frac{\ln(2)}{\ln\left(\frac{3}{2}\right)}<2 \tag{5.4.235}$$

So it is immediate that $q_2=1$ and then as:

$$\varepsilon=\frac{\ln(y_{n-2})}{\ln(y_{n-1})}-q_n \tag{5.4.236}$$

We have:

$$\varepsilon_2=\frac{\ln(y_0)}{\ln(y_1)}-q_2=\frac{\ln(2)}{\ln\left(\dfrac{3}{2}\right)}-1=\frac{\ln(2)-\ln\left(\dfrac{3}{2}\right)}{\ln\left(\dfrac{3}{2}\right)}=\frac{\ln\left(\dfrac{4}{3}\right)}{\ln\left(\dfrac{3}{2}\right)} \tag{5.4.237}$$

Finally we get:

$$\log_2(3)=q_1+\frac{1}{q_2+1/\varepsilon_2}=1+\cfrac{1}{1+\cfrac{1}{\cfrac{\ln\left(\dfrac{4}{3}\right)}{\ln\left(\dfrac{3}{2}\right)}}}=\cfrac{1}{1+\cfrac{\ln\left(\dfrac{3}{2}\right)}{\ln\left(\dfrac{4}{3}\right)}} \tag{5.4.238}$$

etc... etc.

5.5. Set Theory

During our study of numbers, operators, and number theory (in the chapters of the same name), we often used the terms "groups", "rings", "fields", "homomorphism", etc. and thereafter we will continue to do it again many times. Besides the fact that these concepts are of utmost importance, to give demonstrations or build mathematical concepts essential to the study of contemporary theoretical physics (quantum field physics, string theory, standard model, ...), they allow us to understand the components and the basic properties of mathematics and its operators by storing them in separate categories. So, choose to present the Set Theory as the 5th chapter of this textbook is a very questionable choice as rigorously that it is where almost everything begins... However, we still needed to expose the Proof Theory for the notations and methods that will be used here.

Moreover, when teaching modern mathematics in the secondary or primary (in the years 11970 according to holocene calendar), the language of sets and the preliminary study of binary relations to a more rigorous approach to the notion of functions and applications of mathematics in general was introduced (see definition below).

Definition (#5.5.75): We talk about "arrow diagram" (or "sagittal diagram" from latin "sagitta" = arrow) to all diagram showing a correspondence between the two sets of components connected wholly or partially by a set of arrows. When there is no arrows, we then just speak of "Venn diagrams".

For example, the graphical representation of a defined function of the set $E = \{-3,-2,-1,0,1,2,3\}$ to the set $F = \{0,1,2,4,9\}$ (usually denoted $E \mapsto F$) leads to the sagittal diagram below:

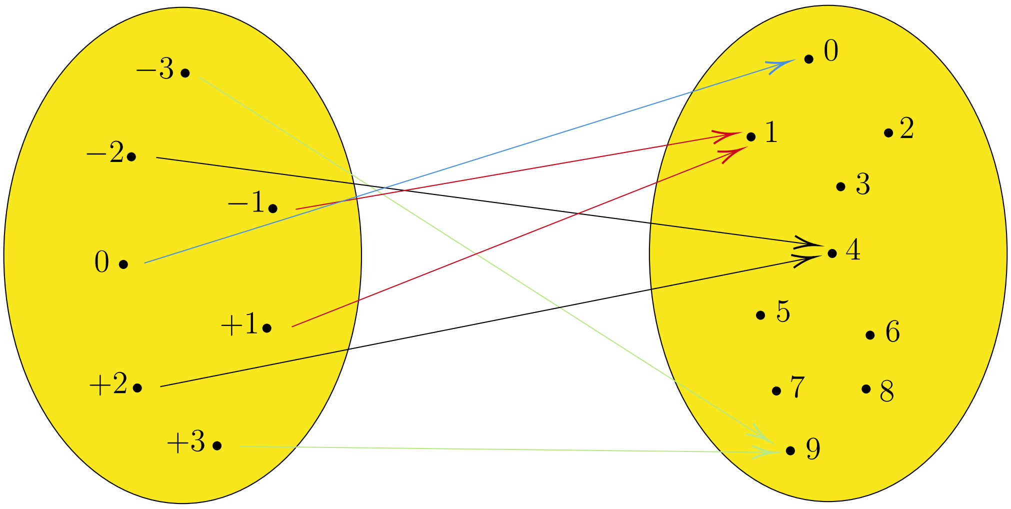

Figure 5.50: **Sagittal diagram example from a definition set to a destination set**

A relation from E to E (usually denoted $E \mapsto E$) provides an arrow diagram of the type:

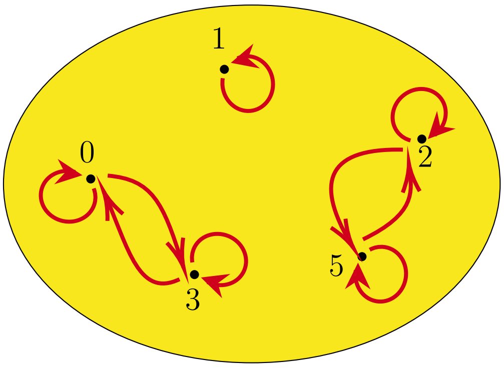

Figure 5.51: **Function returning in its own set of definitions**

The closure of each element showing a "reflexive relation" and the systematic presence of a back arrow indicating a "symmetrical relation".

Definition (#5.5.76): If the target set is identical to the original set, we say that we have a "binary relation".

However choosing to introduce the Set Theory in school classrooms has also some other reason. In fact, for the sake of internal rigour (i.e. not related to reality), a very large part of mathematics was rebuilt within a single axiomatic framework, so named "Set Theory", in the sense that each mathematical concept (previously independent of the other) is returned to a definition where all the logical components come from this same framework: it is regarded as fundamental! Thus, the rigour of reasoning carried out within Set Theory is guaranteed by the fact that the frame is "non-contradictory" or "consistent". Let us see now the definitions that build this framework.

Definitions (#5.5.77):

D1. We name "set" any list, collection or gathering of well-defined objects, explicitly or implicitly.

D2. A "Universe" U is an object whose constituents are sets.

Note that what mathematicians name "Universe" is not a set! In fact it is a model that satisfies to the axioms of sets.

Indeed, we will see that we can not talk about the set of all sets (because this is not a set) to designate the object that consists of all the sets and that's why we talk about "Universe".

D3. We name "elements" or "members of the set" objects belonging to the set and we write:

$$p \in A \tag{5.5.1}$$

if p is an element of the set A and in the contrary case:

$$p \notin A \tag{5.5.2}$$

If B is a "part" of A, or "subset" of A, we write this:

$$B \subset A \quad \text{or} \quad A \supset B \tag{5.5.3}$$

Thus:

$$\forall x, x \in B \Rightarrow x \in A \tag{5.5.4}$$

✍**Examples:**

E1. $A = \{1, 2, 3\}$

E2. $X = \{X \mid x \text{ is a positive integer}\}$

D4. We can provide sets with a number of relations that compare (useful sometimes...) their elements or to compare some of their properties. These relations are named "comparison relations" or "order relations" like $\leq, \geq$ (see section Operators page 290).

D5. Let E be a set, and let $\mathcal{P}$ be a statement depending on a parameter $x \in E$. Let $\mathcal{P}(x)$ be this statement evaluated at x. We will say that $\mathcal{P}$ is a "property on the elements of E" if, for each $x \in E$, the statement $\mathcal{P}(x)$ is a proposition in the mathematical sense, and is therefore either true or false (excluded middle). In this case, we will denote by:

$$\{x \in E | \mathcal{P}(x)\} \tag{5.5.5}$$

the subset of E formed by the elements $x \in E$ for which $\mathcal{P}(x)$ is true.

We note that the excluded middle condition on $\mathcal{P}$ guarantees that the subset:

$$A = \{x \in E | \mathcal{P}(x)\} \tag{5.5.6}$$

is well-defined, meaning that its elements have been well-characterized: if $x \in E$, then $x \in A$ if $\mathcal{P}(x)$ is true, and $x \notin A$ if $\mathcal{P}(x)$ is false. We don't give the list of elements of A, but a property that characterizes its elements: we say that A is given "by comprehension" (as opposed to a set "given by extension"). For example:

$$\{1, 2, 3, 4\} \quad \text{and} \quad \{n \in \mathbb{N}; 1 \leqslant n \leqslant 4\} \tag{5.5.7}$$

are two notations for the same subset of $\mathbb{N}$: the first is in extension, the second in comprehension.

Remarks

R1. The structure of ordered set has original been set up in the framework of the Numbers Theory by Cantor and Dedekind.

R2. As we have proved in the section on Operators, $\mathbb{N}, \mathbb{Z}, \mathbb{Q}, \mathbb{R}$ are totally ordered by the usual relations $\leq, \geq$. The relation $<$, often named "strict order" is not an order relation because not reflexive and not antisymmetric (see section Operators page 290). For example, in $\mathbb{N}$ the relation "a divides b" , often denoted by the symbol "|" is a partial order.

R3. If $\mathcal{R}$ is an ordering on E and F is a subset of E, the restriction to F of the relation $\mathcal{R}$ is an order on F, named "order induced by $\mathcal{R}$ in F".

R4. If $\mathcal{R}$ is an order on E, the relation $\mathcal{R}'$ defined by:

$$x\mathcal{R}'y \Leftrightarrow y\mathcal{R}x$$

is an order on E, named "reciprocal order" of $\mathcal{R}$. The reciprocal order $\leq$ of the usual order is the order noted $\geq$ and reciprocal order to the order "a divides b" in $\mathbb{N}$ is the order "b is a multiple of a".

The set is the basic mathematical entity whose existence is defined: it is not defined as itself but by its properties, given by the axioms. It uses a human process: a kind of categorization feature, which allows thought to distinguish several independent qualified elements.

Theorem 5.29. We can demonstrate from these concepts, that the number of subsets of a set of cardinal n is 2^n.

Proof 5.29.1. First there is the empty set $\varnothing$, that is 0 items chosen from n, i.e. C_0^n (notation of binomial coefficient non-conform with ISO 31-11!) as we have seen in the section of Probabilities:

$$C_k^n=\vec{v}=\binom{n}{k}=\frac{A_n^k}{k!}=\frac{n!}{k!\,(n-k)} \qquad (5.5.8)$$

and so on...

The number of subsets (cardinal) of E corresponds to the summation of all binomial coefficients:

$$\boxed{\operatorname{Card}\left(P\left(E\right)\right)=\sum_{k=0}^{n}C_k^n} \qquad (5.5.9)$$

But, we have (see section Calculus page 1364):

$$(x+y)^n=\sum_{k=0}^{n}C_k^n x^k y^{n-k} \qquad (5.5.10)$$

therefore:

$$\boxed{\operatorname{Card}\left(P\left(E\right)\right)=\sum_{k=0}^{n}C_n^k 1^k 1^{n-k}=(1+1)^n=2^n} \qquad (5.5.11)$$

■ Q.E.D.

✍**Example:**

Consider the set $S = \{x_1, x_2, x_3\}$, we have the set of all parts of $P(S)$ consisting of:

- The empty set: $\{\} = \varnothing$
- The singletons: x_1, x_2, x_3
- The duets: $x_1, x_2, x_1, x_3, x_2, x_3$
- Itself: $\{x_1, x_2, x_3\}$

Such that:

$$P(S) = \{\varnothing, x_1, x_2, x_3, x_1, x_2, x_1, x_3, x_2, x_3, x_1, x_2, x_3\} \tag{5.5.12}$$

What makes indeed 8 elements!

Remark

The order in which the elements are differentiated does not come into account when counting parts of the original set.

In Applied Mathematics, we work almost exclusively with sets of numbers. Therefore, we will limit our study of definitions and properties of these.

Now let us formalize the basic concepts for working with the most common sets we encounter in the basic school curriculum.

5.5.1 Zermelo-Fraenkel Axiomatic

The Zermelo-Fraenkel axiomatic, abbreviated sometimes "ZF-C axioms" shown below was formulated by Ernst Zermelo and Abraham Adolf Fraenkel specified by the early 120th century (holocene calendar) and completed by the axiom of choice (hence the capital C in ZF-C). It is considered as the most natural axiomatic structure in the context of set theory.

Remark

There are many other axiomatic structures, based on the more general concept of "class", as developed by von Neumann, Bernays and Gödel (for the notations, see section Proof Theory page 131).

Strictly technically speaking..., the ZF axioms are statements of calculation for first order predicate (see section Proof Theory page 163) egalitarian in a language with only one primitive symbol for membership (binary relation). The following should therefore only be seen as an attempt (...) to express in English the expected significance of these axioms.

A1. Axiom of extensionality:

Two sets are equal if and only if they have the same elements. This is what we denote:

$$A = B \Leftrightarrow (\forall x \in A, x \in B) \wedge (\forall x \in B, x \in A) \tag{5.5.13}$$

So A and B are equal if every element x of A is also in B and every element x of B also belongs to A.

A2. Axiom of empty set:

The empty set exists, we denote it:

$$\varnothing \tag{5.5.14}$$

and it has no element, its cardinality is therefore 0.

In fact this axiom can be deduced from another axiom that we will see a little further but it is convenient to introduce it by convenience for teaching in high-school classes.

A3. Axiom of pairing:

If A and B are two sets, then, there exist a set C containing A and B alone and as components. This set C is then denoted $\{A, B\}$.

From the perspective of the sets considered elements that gives:

$$\forall A \forall B \exists C : \quad A \in C \wedge B \in C \tag{5.5.15}$$

This axiom also shows the existence of the "singleton" a set noted:

$$\{X\} \tag{5.5.16}$$

which is a set whose only element is X (and therefore with unitary cardinal). We simply need to apply the axiom asking equality between A and B.

A4. Axiom of the sum (also named "axiom of union"):

This axiom allows us to build the union (merge) of sets. Said in a most common way: the union (merge) of any family of a set, is... a set.

The union of any family of sets is often denoted:

$$\bigcup_i A_i \tag{5.5.17}$$

or if we take some of its elements:

$$\bigcup_{x \in A} x_i \tag{5.5.18}$$

A5. Axiom of subsets:

This axiom defines that for any set A, the set of all its parts $P(A)$ exists (do not confuse with the "P" of probability!).

So for any set A, we can associate a set B which contains exactly the parts C (verbatim the subsets) of the first:

$$\forall A \exists B \forall C : \quad (C \in B \Leftrightarrow C \subset A) \tag{5.5.19}$$

A6. Axiom of infinity:

This axiom express the fact that there exist an infinite set. To formalize it, we say that there exist a set, named "autosuccessor set" A containing $\varnothing$ (the empty set) such that if x belongs to A, then also $x \cup \{x\}$ belongs to A:

$$A \text{ is autosuccessor} \Leftrightarrow (\varnothing \in A) \wedge (x \in A \Rightarrow (x \cup \{x\}) \in A) \tag{5.5.20}$$

This axiom expresses for example that the set of integers exists. Indeed, $\mathbb{N}$ is so the smallest autosuccessor set in the sense of inclusion $\mathbb{N} = \{\varnothing, \{\varnothing, \{\varnothing, \ldots\}\}\}$ and by convention we note (where we build the Natural Set):

$$\begin{aligned} 0 &= \varnothing \\ 1 &= \{\varnothing\} \\ 2 &= \{\varnothing, \{\varnothing\}\} \\ \ldots \end{aligned} \tag{5.5.21}$$

A7. Axiom of regularity (also named "foundation axiom"):

The main purpose of this axiom is just to eliminate the possibility of having A as part of itself.

Thus, for any non-empty set A, there exists a set B which is an element of A such that no element of A is an element of B (you must distinguish the level of the language used, a set and its elements have not the same status!) that we note:

$$\forall A \neq \varnothing : \quad \exists B \in A, A \cap B = \varnothing \tag{5.5.22}$$

and thus result we expected to have:

$$\forall A, A \notin A \tag{5.5.23}$$

Proof 5.29.2. Indeed, let A be a set such that $A \in A$. Consider the singleton $\{A\}$, set whose only element is A. According to the axiom of foundation, we must have an element of this singleton that has no element in common with him. But the only possible element is A itself , that is to say that we must have:

$$A \cap \{A\} = \varnothing \tag{5.5.24}$$

But by hypothesis $A \in A$ and by construction $A \in \{A\}$. So:

$$A \in (A \cap \{A\}) \tag{5.5.25}$$

which contradicts the previous assertion. Therefore:

$$A \notin A \tag{5.5.26}$$

■ Q.E.D.

Remark

Every set contains as a subset the empty set $\emptyset = \{\}$, and it also equally trivially contains itself as a subset. For the empty set these two cases are in fact the same, and indeed the empty set is the unique subset of the empty set. So we can form the set $\{\emptyset\}$ whose only member is $\emptyset$ but note that $\{\emptyset\} \neq \emptyset$, because $\emptyset \in \{\emptyset\}$ however $\emptyset \notin \emptyset$. In other words: nothing can be part of something but cannot contain itself! That's why there is always something instead of nothing!

A8. Axiom of replacement (also named "Axiom schema of replacement"):

This axiom expresses the fact that if a formula f is a functional then for any set A, there is a set B consisting precisely of the images of A by this function.

So, in a little more formally way, the set A of elements a and a binary relation f (which is quite generally a functional), there exist a set B consisting of elements b such that $f(a, b)$ is true. If f is a function where b is not free then it means that:

$$b = f(A) \text{ and } B = f(A) \tag{5.5.27}$$

In a technical way we write this axiom as following:

$$\forall A\ \exists a \in A\ \exists! f : \quad f(a,b) \Rightarrow \exists B \forall a \in A \exists b \in B f(a,b) \tag{5.5.28}$$

So for every set A and any item it contains, there is one and only one b defined by the functional f such that there exists a set B for which any element a belonging to the set A there is a b belonging to set B defined by the functional f.

Let's see an example with the following binary predicate that for the value of any a from A determines the value of any b of B:

$$P(a,b) = (a = 1 \wedge b = 2) \vee (a = 3 \wedge b = 4) \tag{5.5.29}$$

Therefore from the knowledge that a is equal 1 we derive that b is equal 2 and similarly (i.e. by replacement) when a is equal 3, we derive that b is equal 4.

We see well through this small example the strong relation that exists considering the predicate P as a naive function! Moreover, as there is an infinity of possible functions f, the replacement scheme is considered as an infinite number of axioms.

A9. Axiom of selection (also named "Axiom comprehension schema"):

This axiom simply expresses that for any set A and any property P expressible in the language of set theory, the set of all elements of A satisfying the property P exist.

So more formally, to any set A and any condition or proposition $P(x)$, there is a set B whose elements are exactly the elements x of A for which $P(x)$ is true. This is what we write:

$$B = \{x \in A : P(x)\} \tag{5.5.30}$$

In a more comprehensive and rigorous way we have in fat for any functional f that does not include a as free variable:

$$\forall A \exists B \forall a : \quad a \in B \Leftrightarrow a \in A \wedge f \tag{5.5.31}$$

It is typically the axiom that we use to construct the set of even numbers:

$$\{a \in \mathbb{N} \mid \exists b \in \mathbb{N}, a = 2b\} \tag{5.5.32}$$

or to prove the existence of the empty set (which invalidates the axiom of the empty set) because you just have to ask that there exist a set that satisfies the property:

$$A \neq A \tag{5.5.33}$$

and regardless of the set A. And only the empty set satisfies this property by the selection axiom.

The compliance with the strict conditions of this axiom eliminates the paradoxes of the "naive set theory", as Russell's paradox or Cantor's paradox who invalidated the naive set theory.

For example, consider the Russell set R of all sets that do not contain themselves (note that we give a property of R without specifying what is this set):

$$R = \{E : E \notin E\} \tag{5.5.34}$$

The problem is to know whether or not R contains itself or not. If $R \in R$, then, R is self-contained, and, by definition $R \notin R$, and vice versa. Each possibility is contradictory.

If we now denote by C the set of all sets (Cantor Universe) we have in particular:

$$P(C) \in C \tag{5.5.35}$$

which is impossible (i.e. with the power of the continuum of real numbers), according to Cantor's theorem (see section Numbers page 225).

These "paradoxes" (or "syntactic antinomies") come from a non-compliance with the conditions of application of the selection axiom: to define E (in the example of Russell), there must be a proposition P which bears on the set R, which should be explicated. The proposal defining the set of Russell or that of Cantor does not indicate what is the set E. It is therefore invalid!

A very nice and well known example (this is why we present it) helps to better understand (this is the "Russell paradox" which we have already spoken about in length in the section on Proof Theory page 138):

A young student went one day to his barber. He entered into conversation and asked him if he had many competitors in his pretty city. Seemingly innocent way, the barber replied, *« I have no concurrence. Because of all the men of the city, I obviously do not shave those who shave themselves, but I am fortunate to shave. all those who do not shave themselves»*.

What then in such a so simple statement could take to the fault the logic of our young smart student?

The answer is in fact innocent, until we decide to apply to the case of the barber: Does he shaves himself, Yes or No?

Suppose he shaves himself: he then belongs to the category of those who shave themselves, those who the barber said he did of course not shave.... So he does not shave himself..........

Finally, this unfortunate barber is in a strange position: if he shaves himself, he does not shave himself, and if he does not shave himself, he shaves himself. This logic is self-destructive, contradictory stupidly, rationally irrational.

Then comes the selection axiom: We exclude the barber of all persons to which the declaration applies. Because in reality, the problem is that the barber is a member of the set of all the men of the city. So what applies to all men does not apply to the individual case of the barber.

A10. Axiom of choice:

Given a set A of non-empty mutually disjoint sets, there exist a set B (the set of choices for A) containing exactly one element for each member A.

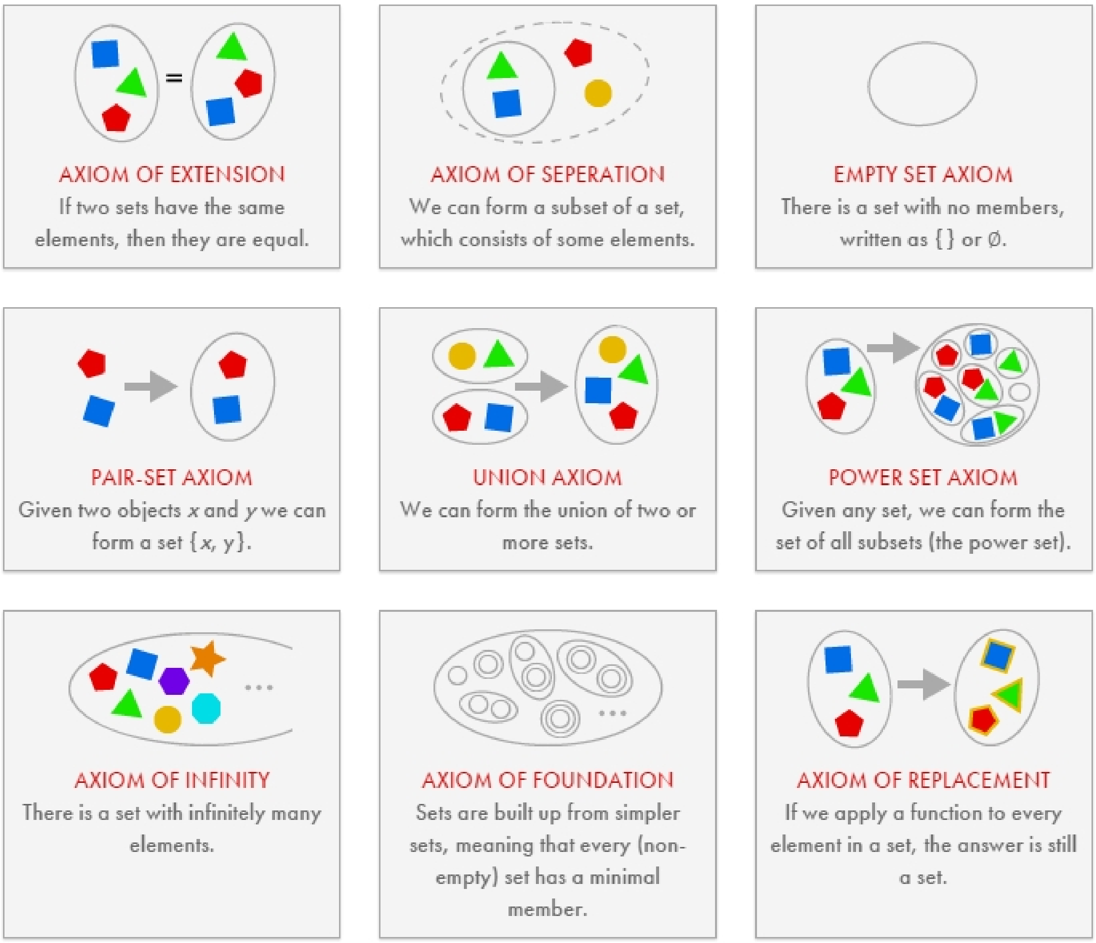
However let us indicate that the issue of the axiomatization and therefore of the foundations found himself still shaken by two questions at the time of their construction: what valid axioms must be chosen and in a system of axioms are the mathematics coherent (do we not have a risk of seeing a contradiction)?

The first issue was first raised by the continuum hypothesis: if we can put two sets of numbers in correspondence term to term, they have the same number of elements (cardinal). We can thus map all integer numbers $\mathbb{N}$ with rational numbers $\mathbb{Q}$ as we have shown in the section on Numbers (page 225), so they have the same cardinality, be we can not map integer numbers with all the real numbers. The question then is whether there is a set whose number of elements would be located between the two or not? This question is important to build the classical theory of analysis and mathematicians usually choose to say there is none, but we can also say the opposite.

In fact the continuum hypothesis is linked in a more profound way we could thing to the axiom of choice which can also be formulated as follows: if C is a collection of non-empty sets then we can select any element of each set of the collection. If C has a finite number of elements or a countable number of elements, the axiom seems pretty trivial: we can sort and number the sets of C and the selection of an element in each set is simple. Where it begin to get complicated is when the set C has the power of the continuum: how to choose the elements if it is not possible to number them?

Finally in 11938 (holocene calendar) Kurt Gödel shows that set theory is consistent without the axiom of choice and without the continuum hypothesis as well as with! And to end it all Paul Cohen in 11963 (holocene calendar) shows that the axiom of choice and the continuum hypothesis are not related.

Ok to make a pedagogical summary of all this stuff consider the following figure (excluding the axiom of choice):



AXIOM OF EXTENSION
If two sets have the same elements, then they are equal.
AXIOM OF SEPERATION
We can form a subset of a set, which consists of some elements.
EMPTY SET AXIOM
There is a set with no members, written as {} or Ø.
PAIR-SET AXIOM
Given two objects x and y we can form a set {x, y}.
UNION AXIOM
We can form the union of two or more sets.
POWER SET AXIOM
Given any set, we can form the set of all subsets (the power set).
AXIOM OF INFINITY
There is a set with infinitely many elements.
AXIOM OF FOUNDATION
Sets are built up from simpler sets, meaning that every (non-empty) set has a minimal member.
AXIOM OF REPLACEMENT
If we apply a function to every element in a set, the answer is still a set.

Figure 5.52: **Zermelo-Frankel axioms visual summary (source:?)**

5.5.1.1 Cardinals

Definition (#5.5.78): Sets are said to be "equipotent" if there exists a bijection (one-one correspondence) between these sets. We thus say they have same "cardinal" that the norm ISO 3111 advocated to write $card(S)$ but in this textbook we will also use the notation $\text{Card}(S)$ (many U.S. books use non-official notation that looks exactly like the absolute value $\mid S\mid$ or $\#S$).

Thus, more rigorously, a cardinal (which quantifies the number of items in the set) is an equivalence class (see section Operators page 292) for the relation of equipotence.

Remark

Cantor is the main creator of set theory, in a form that we name today "naive set theory". But, apart to elementary considerations, his theory was also consisting of higher abstraction levels. The real novelty of the Cantor theory is that it lets talk about infinity. For example, an important idea Cantor was precisely to define the "equipotence".

If we write $c_1 = c_2$ as equality of cardinals, we mean by that there are two equipotent sets A and B such that:

$$c_1 = \text{Card}(A) \quad \text{and} \quad c_2 = \text{Card}(B) \tag{5.5.36}$$

Cardinals can be compared. The order thus defined is a total ordering (see section Operators page 291) between the Cardinals (the proof that the order relation is complete uses the axiom of choice and the proof that it is antisymmetric is known under the name of Cantor-Bernstein's theorem that we will demonstrate further below).

Say that $c_1 < c_2$ means in simple language that A is equipotent to a proper part of B, but B is not equipotent to any own part of A. Mathematicians would say that $\text{Card}(A)$ is smaller or equal to the $\text{Card}(B)$ if there is an injection of A into B.

We saw during our study of numbers (see section Numbers page 389), especially of transfinite numbers, that an equipotent set (or bijection) to $\mathbb{N}$ was told to "countable set".

Let us now see this notion a little more in detail:

Let A be a set, if there is an integer n such that there is at least for each element of A a corresponding item int the set $\{1, 2, \ldots, n\}$ (in fact this is rigorously a bijection... concept that we will define later) then we say that the cardinal of A, denoted $\text{Card}(A)$ or $\text{Card}(A)$ is a "finite cardinal" and its value is n.

Otherwise, we say that the set A has an "infinite cardinal" and we write:

$$\text{Card}(A) = +\infty \tag{5.5.37}$$

A set A is "countable" if there is a bijection between A and (N). A set of numbers A is "countable" if there is a bijection between A and part of (N). A set at maximum countable is thus of finite cardinal, or countable.

We can therefore check the following proposals:

P1. A part of a countable set is at most countable.

P2. A set containing a non-countable set is also not countable.

P3. The product of two countable sets is countable.

Remark

We can restrict a set of numbers relatively with the null element and the negative or positive elements in it and therefore we write (example for the real set):

$$\begin{aligned}
\mathbb{R}^* &= \mathbb{R} \setminus \{\varnothing\} \\
\mathbb{R}_+ &= \{x \mid x \in \mathbb{R} \text{ and } x \geq 0\} \\
\mathbb{R}_- &= \{x \mid x \in \mathbb{R} \text{ and } x \leq 0\} \\
\mathbb{R}_+^* &= \mathbb{R}_+ \setminus \{\varnothing\} \\
\mathbb{R}_-^* &= \mathbb{R}_- \setminus \{\varnothing\}
\end{aligned} \tag{5.5.38}$$

These concepts are similar for $\mathbb{N}, \mathbb{Z}, \mathbb{Q}$ (the set of complex numbers $\mathbb{C}$ being not ordered, the second and third line does not apply to).

So any infinite subset of $\mathbb{N}$ is equipotent to $\mathbb{N}$ itself, what may seem counter-intuitive at first...!

In particular, there are as many even integers as any natural integer numbers (use the bijection $f(n) = 2n$) from $\mathbb{N}$ to P, where P is the set of even natural numbers. As many relative numbers as integers, as many integers as rational numbers (see the section Numbers page 225 for the proofs).

Thus we can write:

$$\text{Card}(\mathbb{N}) = \text{Card}(\mathbb{Z}) = \text{Card}(\mathbb{Q}) = \aleph_0 \tag{5.5.39}$$

and more generally, any infinite part of $\mathbb{Q}$ is countable.

Thus we have an important result: any infinite set therefore has an infinite countable part.

Since we have proved in the section on Numbers (page 232) that the set of real numbers $\mathbb{R}$ has the "power of the continuum" and that the set of natural numbers $\mathbb{N}$ has transfinite cardinal $\aleph_0$, Cantor raised the question whether there was a cardinal between the transfinite cardinal $\aleph_0$ and the cardinal of $\mathbb{R}$? In other words, we have an infinite amount of integers, and an even greater amount of real numbers. So does it exist an infinite greater than the infinite of integers and smaller than that of the real numbers?

The problem arose by writing $\aleph_0$ the cardinal of $\mathbb{N}$ and $\aleph_1$ (new) the cardinal of $\mathbb{R}$ and offering to demonstrate or contradict that:

$$\aleph_1 = 2^{\aleph_0} \tag{5.5.40}$$

according to the combinatorial law that gives the number of elements that we can get from all subsets of a set (as we have proved it before).

The rest of his life, Cantor tried, in vain, to prove this result that we name the "continuum hypothesis". He did not succeed and descended into madness. In 19000 (holocene calendar), the International Congress of Mathematicians, Hilbert considered that this was one of the 23 major issues that should be resolved in the 120th century (holocene calendar).

This problem is solved in a rather surprising way. First, in 11938, one of the greatest logicians of the 120th century (holocene calendar), Kurt Gödel showed that the hypothesis of Cantor was not refutable, that is to say, we could never prove that it was false. Then in 11963 (holocene calendar), the mathematician Paul Cohen closed the debate. He demonstrated that we could never prove that it was true!!! We can conclude rightly that Cantor had become mad to try to demonstrate a problem that could not be proved.

5.5.1.2 Cartesian Product

Definition (#5.5.79): If E and F are two sets, we name "Cartesian product of E by F" the set noted $E \times F$ (not to be confused with the vector product notation) consisting of all possible pairs (e, f) where e is an element of E and f an element of F.

More formally:

$$\boxed{E \times F = \{(e, f) \mid e \in E \wedge f \in F\}} \tag{5.5.41}$$

We note the Cartesian product of E by itself:

$$E \times E = E^2 \tag{5.5.42}$$

and then we say that E^2 is the "set of pairs of elements of E".

We can perform the Cartesian product of a sequence $E_1 \times E_2 \times \ldots \times E_n$ of sets and get all n-tuples $(e_1, e_2, \ldots, e_n)$ where $e_1 \in E_1, e_2 \in E_2, \ldots, e_n \in E_n$.

In the case where all sets E_i are identical to E, the Cartesian product $E_1 \times E_2 \times \ldots \times E_n$ is obviously noted E^n. We then say that e^n is the "set of all n-tuples of elements of E".

If E and F are finite then the Cartesian product $E \times F$ is finished. Moreover:

$$\text{Card}(E \times F) = \text{Card}(E) \cdot \text{Card}(F) \tag{5.5.43}$$

From here we see that if the sets $E_1, E_2, \ldots, E_n$ are finished then the Cartesian product $E_1 \times E_2 \times \ldots \times E_n$ is finished and we have:

$$\text{Card}(E_1 \times E_2 \times \ldots \times E_n) = \prod_{i=1}^{n} \text{Card}(E_i) \tag{5.5.44}$$

In particular:

$$\text{Card}(E^n) = [\text{Card}(E)]^n \tag{5.5.45}$$

if E is a finite set.

✍**Examples:**

E1. If $\mathbb{R}$ is the set of real numbers, then $\mathbb{R}^2$ is the set of all couples of real numbers. In the plane reported to a referential, any point M has the coordinates that are an element of $\mathbb{R}^2$.

E2. When we run two dice whose faces are numbered 1 through 6, each die can be symbolized by the set $E = \{1, 2, 3, 4, 5, 6\}$. The outcome of a roll of dies is then an element of $E^2 = E \times E$. The Cardinal of $E \times E$ is then 36. There are therefore 36 possible results when we launch two dices whose faces are numbered 1 to 6.

Remark

Set theory and the concept of cardinal is the theoretical basis of relational database softwares.

5.5.1.3 Intervals

Let M be a set of any numbers so that $M \subset \mathbb{R}$ (particular but frequent example). We have for definitions: **Definitions (#5.5.80):**

D1. $x \in \mathbb{R}$ is named "upper bound" of the set M, if $x \geq m$ for $\forall m \in M$. Conversely, we speak about "lower bound" (so do not confuse the concept of terminal with the concept of interval!).

D2. Either $M \subset \mathbb{R}, M \neq \varnothing$. $x \in \mathbb{R}$ is named the "smallest upper bound" noted:

$$x = \text{sup} M \tag{5.5.46}$$

of M if x is an upper bound of M and if for any upper bound $y \in \mathbb{R}$ we have $x \leq y$. Conversely, we speak about the "smaller lower bound" that we note:

$$x = \text{inf} M \tag{5.5.47}$$

The definitions are equivalent in the context of functional analysis (see section of the same name page 2170) as the functions are defined on sets.

Indeed, let f be a function whose domain of definition I swept all $\mathbb{R}$. We note that:

$$f : E \mapsto \mathbb{R} \tag{5.5.48}$$

and let $x_0 \in \mathbb{R}$.

Definitions (#5.5.81):

D1. We say that f has a "global maximum" on x_0 if:

$$\forall x \in E : \quad f(x) \leq f(x_0) \tag{5.5.49}$$

D2. We say that f has a "global minimum" on x_0 if:

$$\forall x \in E : \quad f(x) \geq f(x_0) \tag{5.5.50}$$

In each of these cases, we say that f has an "global extremum" on x_0 (it is a concept that we often use in the sections of Analytical Mechanics page 3152 and Numerical Methods page 6272!).

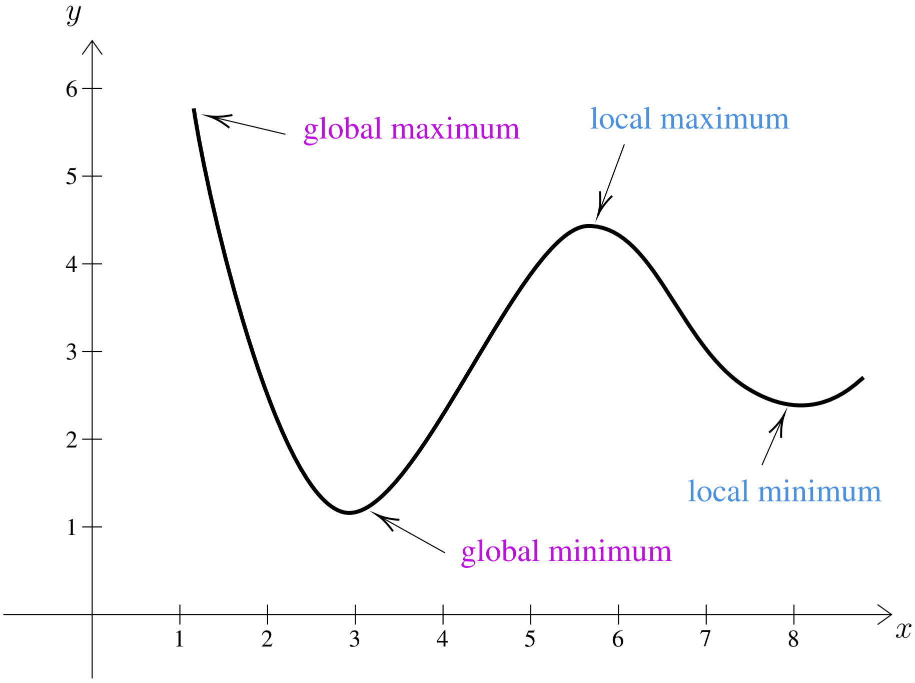


Figure 5.53: Global/Local naximum and minimum example (source: Wikipedia)

D3. f is "upper bounded" if there is a real number M such as $\forall x \in I, f(x) \leq M$. In this case, the function has an upper bound of f on its domain of definition I traditionally denoted:

$$\sup_I f \tag{5.5.51}$$

D4. f is "lower bounded" if there is a real M such that $\forall x \in I, f(x) \geq M$. In this case, the function has a lower bound of f on its domain of definition I traditionally denoted:

$$\inf_I f \tag{5.5.52}$$

D5. We say that f is "bounded" if it is both lower bounded and upper bounded (typically the case of trigonometric functions).

5.5.2 Set Operations

We can build from at least three sets A, B, C all sets operations (which notations are due to Richard Dedekind) existing in set theory (very useful in the study of probability and statistics).

Remark

Some of the notations below will be frequently use later in relatively complex theorems, so it is necessary to understand them deeply!

Thus, we can construct the following set operations:

5.5.2.1 Inclusion

In the simplest case, we define the "inclusion" as:

$$\boxed{A \subset B \Leftrightarrow \forall x \left[x \in A \Rightarrow x \in B \right]} \tag{5.5.53}$$

In a non-specialized language here's C: A is "included" (is a "part", or is a "subset") in B then for all x belonging to each of these x also belongs to B:

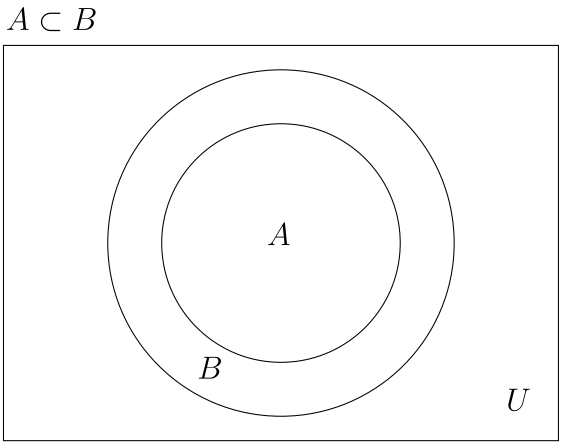

Figure 5.54: **Visual example (Euler diagram) of the inclusion**

where the U in the lower right corner of the figure represents the Cantor Universe.

From this it follows the following properties:

P1. If $A \in B$ and $B \in A$ then it implies $A = B$ and vice versa.

P2. If $A \in B$ and $B \in C$ then implies $A \in C$.

5.5.2.2 Intersection

In the simplest case, we define the "intersection" as:

$$\boxed{A \cap B = \{x \mid x \in A \wedge x \in B\}} \tag{5.5.54}$$

In a non-specialized language here's what you have to read: the "intersection" of sets A and B consists of all the elements that are both in A and in B:

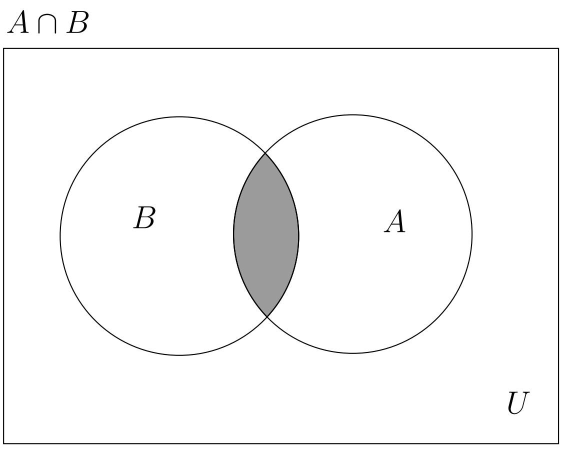

Figure 5.55: **Visual example (Euler diagram) of the intersection**

More generally, if (A_i) is a family of sets indexed by $i \in I$, the intersection of the $(A_i), i \in I$ is denoted:

$$\bigcap_{i \in I} A_i \qquad (5.5.55)$$

This intersection is explicitly defined by:

$$\bigcap_{i \in I} A_i = \{x \mid \forall i \in I x \in A_i\} \qquad (5.5.56)$$

That is to say the intersection of the family of indexed sets includes all x that are located in each set of all sets of the family.

Given two sets A and B, we say they are "disjoint" if and only if:

$$A \cap B = \varnothing \qquad (5.5.57)$$

Furthermore, if:

$$A \cap B = \varnothing \Leftrightarrow \text{Card}(A \cup B) = \text{Card}(A) + \text{Card}(B) \qquad (5.5.58)$$

Mathematicians note that:

$$A \sqcup B \qquad (5.5.59)$$

and name it "disjoint union".

We sometimes joke that knowledge is built on the disjunction... (those who understand will appreciate...).

Definition (#5.5.82): A collection $S = \{S_i\}$ of non-empty sets form a "partition" of a set A if the following properties hold:

P1. $\forall S_i, S_j \in S$ and $i \neq j \Rightarrow S_i \cap S_j = \varnothing$

P2. $A=\bigcup_{S_i\in S} S_i$

✍**Example:**

The set of even numbers and the set of odd numbers are a partitions of $\mathbb{Z}$.

The intersection law is trivially a commutative law (see further below the definition of the concept of "law") as:

$$A\cap B=B\cap A \tag{5.5.60}$$

5.5.2.3 Union

In the simplest case, we define the "union" (also sometimes named "merge") as:

$$\boxed{A\cup B=\{x\mid x\in A\vee x\in B\}} \tag{5.5.61}$$

In a non-specialized language here's what you have to read: the "union" (or "merge") of the sets A and B is the set of elements that are in A plus those that are in B.

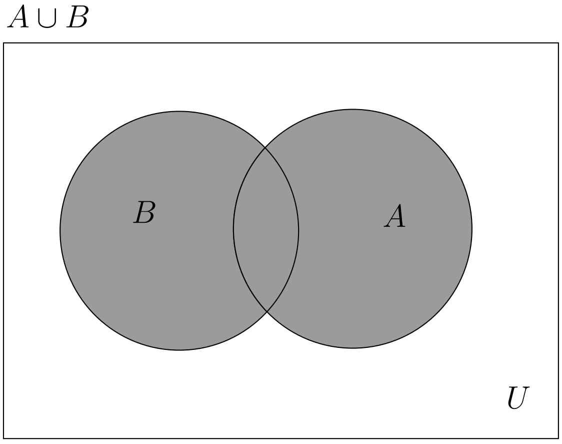

Figure 5.56: Visual example (Euler diagram) of the union

More generally, if (A_i) is a family of sets indexed by $i\in I$, the union of the $(A_i),i\in I$ is denoted:

$$\bigcup_{i\in I} A_i \tag{5.5.62}$$

This union is explicitly defined by:

$$\bigcup_{i\in I} A_i=\{x\mid \exists i\in I x\in A_i\} \tag{5.5.63}$$

That is to say that the union of the family of indexed sets includes all x for which there is a set indexed by i such that x is included in one of the set A_i.

We have the following distributive properties:

$$\begin{aligned}\left(\bigcup_{i\in I} A_i\right)\cap B=\bigcup_{i\in I}(A_i\cap B)\\ \left(\bigcap_{i\in I} A_i\right)\cup B=\bigcap_{i\in I}(A_i\cup B)\end{aligned} \tag{5.5.64}$$

The law of union $\cup$ is a commutative law (see further below the definition of the concept of "law") as:

$$A\cup B=B\cup A \tag{5.5.65}$$

We also name "idempotences laws" the relations (note that for the general culture):

$$\begin{aligned}A\cap A=A\\ A\cup A=A\end{aligned} \tag{5.5.66}$$

and "absorptions laws" the relations:

$$\begin{aligned}A\cap(A\cup B)=A\\ A\cup(A\cap B)=A\end{aligned} \tag{5.5.67}$$

The laws of intersection and union are associative, such that:

$$\begin{aligned}A\cap(B\cap C)=(A\cap B)\cap C\\ A\cup(B\cup C)=(A\cup B)\cup C\end{aligned} \tag{5.5.68}$$

and distributive such that:

$$\begin{aligned}A\cap(B\cup C)=(A\cap B)\cup(A\cap C)\\ A\cup(B\cap C)=(A\cup B)\cap(A\cup C)\end{aligned} \tag{5.5.69}$$

If we recall the concept of "cardinal" (see above) we have with the previously defined operations, the following relation:

$$\text{Card}(A\cup B)=\text{Card}(A)+\text{Card}(B)-\text{Card}(A\cap B) \tag{5.5.70}$$

Hence if $A\cap B=\varnothing$:

$$\text{Card}(A\cup B)=\text{Card}(A)+\text{Card}(B) \tag{5.5.71}$$

5.5.2.4 Difference

In the simplest case, we define the "difference" as:

$$\boxed{A\setminus B=\{x\mid x\in A\wedge x\notin B\}} \tag{5.5.72}$$

In a non-specialized language here's what you have to read: The "difference" of the sets A and B consists of all the elements found only in A (and thus excluding those of B):

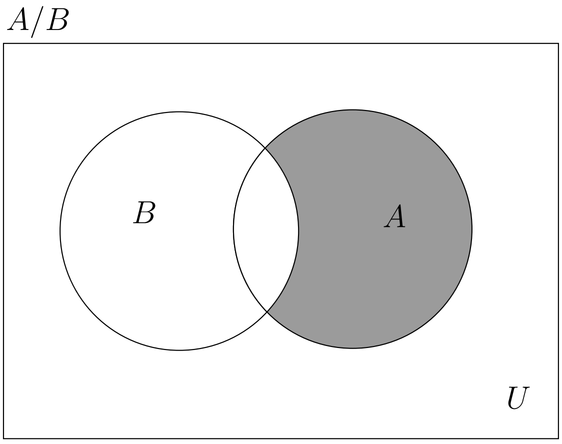

Figure 5.57: Visual example (Euler diagram) of the difference

5.5.2.5 Symmetric Difference

Let U be a set. For any $A, B \subseteq U$ we define the "symmetric difference" $A\delta B$ between A and B by:

$$\boxed{A \triangle B = (A \setminus B) \cup (B \setminus A)} \tag{5.5.73}$$

Or more explicitly using the "exclusive or" in (boolean) logic (see page 146):

$$\begin{aligned} A \oplus B = A\triangle B &= \{x : (x \in A) \oplus (x \in B)\} \\ &= \left(A \cap B^{\complement}\right) \cup \left(A^{\complement} \cap B\right) = \{x : ((x \in A) \wedge (x \notin B)) \vee ((x \notin A) \wedge (x \in B))\} \\ &= (A \cup B) \cap (A \cap B)^{\complement} = \{x : ((x \in A) \vee (x \in B)) \wedge \neg((x \in A) \wedge (x \in B))\} \end{aligned} \tag{5.5.74}$$

In a non-specialized language here's what you have to read: The "symmetric difference" of the sets A and B consists of all items that are only in A and those found only in B (we pass aside elements that are common):

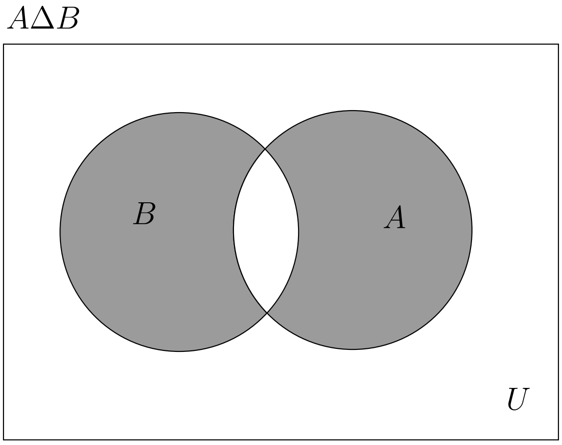

Figure 5.58: Visual example (Euler diagram) of the symmetric difference

So as we can see we have:

$$A \triangle B = (A \cup B) \setminus (A \cap B) \tag{5.5.75}$$

Some trivial properties are given below:

- P1. Commutativity: $A \bigtriangleup B = B \bigtriangleup A$
- P2. Complementarity (see definition below): $A^c \bigtriangleup B^c = A \bigtriangleup B$
- P3. $A \bigtriangleup B = (A \cup B) \setminus (A \cap B)$

5.5.2.6 Product

In the simplest case, we define the "set product" or "cartesian product" as:

$$\boxed{A \times B = \{(x,y) \mid x \in A \wedge y \in B\}} \tag{5.5.76}$$

In a non-specialized language here's what to you have to read: "product" (not to be confused with the multiplication or cross product of vectors) of two sets A and B is the set of pairs such as each element of each set is combined with all elements of the other set.

The product set of real numbers for example generates the plane where each element is defined by X and Y axis.

We often find products sets in mathematics and physics when we work with functions. For example, a function of two real variables which gives real output will be written:

$$\underset{\mathbb{R}\times\mathbb{R}\longrightarrow\mathbb{R}}{f(x,y)} \rightarrow z \tag{5.5.77}$$

or more simply:

$$f(x,y) = z \tag{5.5.78}$$

5.5.2.7 Complementarity

In the simplest case, we define the "complementarity" as:

$$\boxed{\forall A \subset U \quad \bar{A} = \{x \mid x \in U, x \notin A\}} \tag{5.5.79}$$

In a non-specialized language here's what you have to read: The "complementary" is defined as taking a set U and a subset A of U then the complement of A in U is the set of elements that are in U but not in A:

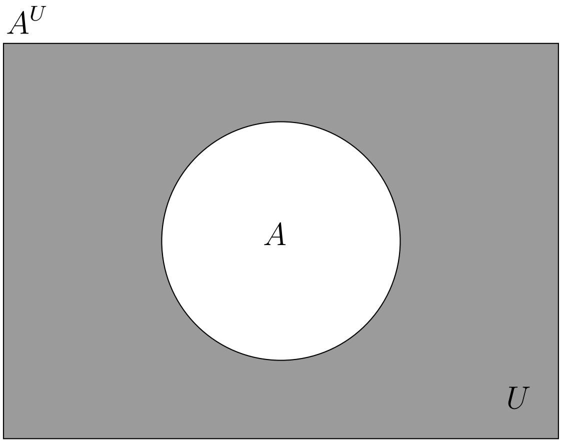

Figure 5.59: **Visual example (Euler diagram) of the complementarity**

Other notations of complementarity that is sometimes found in the literature and the following book are (depending on the context to avoid confusion with other stuff):

$$_U A^c \text{ or } A^c \tag{5.5.80}$$

or in the particular example above, we could also just write $U \setminus A$.

We have for properties for all A_i included in any B:

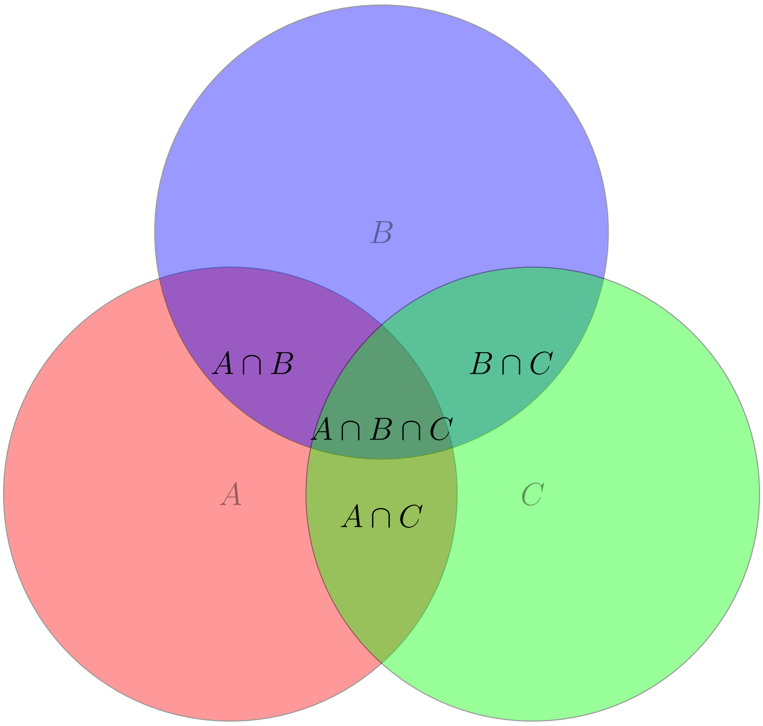
$$\left(\bigcup_{i\in I} A_i\right)^c = \bigcap_{i\in I} A_i^c \tag{5.5.81}$$

$$\left(\bigcap_{i\in I} A_i\right)^c = \bigcup_{i\in I} A_i^c \tag{5.5.82}$$

Here are some trivial properties regarding to complementarity:

$$\begin{aligned}\bar{\bar{A}} &= A\\ A\cap\bar{A} &= \varnothing\\ A\cup\bar{A} &= U\end{aligned} \tag{5.5.83}$$

There are other very important relations that also applied to Boolean logic (see section Logic Systems page 7104). If we consider three sets A, B, C as shown below:



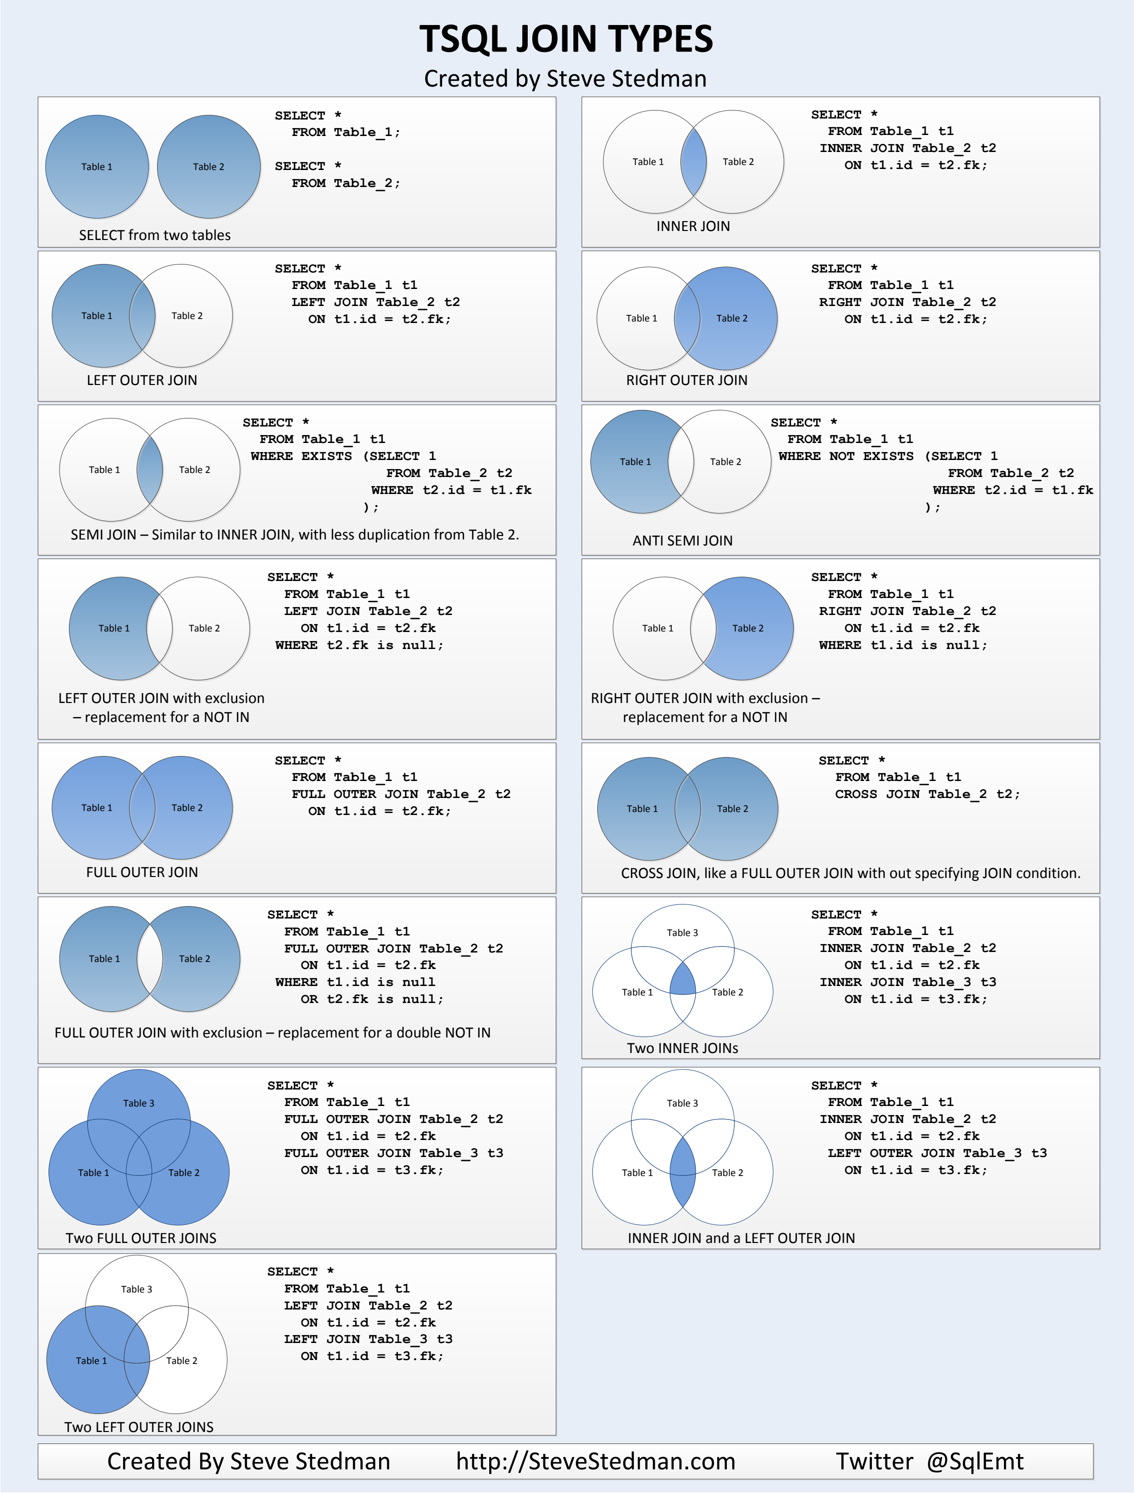
then we have:

$$\begin{aligned} A \setminus (B \cap C) &= (A \setminus B) \cup (A \setminus C) \\ A \setminus B \setminus C &= (A \setminus B) \cup (A \cap B) \end{aligned} \quad (5.5.84)$$

and the famous "De Morgan's laws" in set form (see section Logic Systems page 7110), which are given by the relations:

$$\boxed{\begin{aligned} \overline{A \cap B} &= \bar{A} \cup \bar{B} \\ \overline{A \cup B} &= \bar{A} \cap \bar{B} \end{aligned}} \quad (5.5.85)$$

We would like indicate before moving on to another topic, that a significant number of adults in employment (mostly managers) having forgotten the previous defined concepts after leaving high school must study them again when they learn the SQL language (Structured Query Language) which is the most common worldwide language to query corporate databases servers in the 120th and 121st century (holocene calendar). Most of them learn in training centers the following scheme to build queries with joins:



TSQL JOIN TYPES

Created by Steve Stedman

```
SELECT *
  FROM Table_1;

SELECT *
  FROM Table_2;
```

SELECT from two tables

```
SELECT *
  FROM Table_1 t1
 INNER JOIN Table_2 t2
    ON t1.id = t2.fk;
```

INNER JOIN

```
SELECT *
  FROM Table_1 t1
  LEFT JOIN Table_2 t2
    ON t1.id = t2.fk;
```

LEFT OUTER JOIN

```
SELECT *
  FROM Table_1 t1
 RIGHT JOIN Table_2 t2
    ON t1.id = t2.fk;
```

RIGHT OUTER JOIN

```
SELECT *
  FROM Table_1 t1
 WHERE EXISTS (SELECT 1
                 FROM Table_2 t2
                WHERE t2.id = t1.fk
              );
```

SEMI JOIN – Similar to INNER JOIN, with less duplication from Table 2.

```
SELECT *
  FROM Table_1 t1
 WHERE NOT EXISTS (SELECT 1
                     FROM Table_2 t2
                    WHERE t2.id = t1.fk
                  );
```

ANTI SEMI JOIN

```
SELECT *
  FROM Table_1 t1
  LEFT JOIN Table_2 t2
    ON t1.id = t2.fk
 WHERE t2.fk is null;
```

LEFT OUTER JOIN with exclusion
– replacement for a NOT IN

```
SELECT *
  FROM Table_1 t1
 RIGHT JOIN Table_2 t2
    ON t1.id = t2.fk
 WHERE t1.id is null;
```

RIGHT OUTER JOIN with exclusion –
replacement for a NOT IN

```
SELECT *
  FROM Table_1 t1
  FULL OUTER JOIN Table_2 t2
    ON t1.id = t2.fk;
```

FULL OUTER JOIN

```
SELECT *
  FROM Table_1 t1
 CROSS JOIN Table_2 t2;
```

CROSS JOIN, like a FULL OUTER JOIN with out specifying JOIN condition.

```
SELECT *
  FROM Table_1 t1
  FULL OUTER JOIN Table_2 t2
    ON t1.id = t2.fk
 WHERE t1.id is null
    OR t2.fk is null;
```

FULL OUTER JOIN with exclusion – replacement for a double NOT IN

```
SELECT *
  FROM Table_1 t1
 INNER JOIN Table_2 t2
    ON t1.id = t2.fk
 INNER JOIN Table_3 t3
    ON t1.id = t3.fk;
```

Two INNER JOINs

```
SELECT *
  FROM Table_1 t1
  FULL OUTER JOIN Table_2 t2
    ON t1.id = t2.fk
  FULL OUTER JOIN Table_3 t3
    ON t1.id = t3.fk;
```

Two FULL OUTER JOINS

```
SELECT *
  FROM Table_1 t1
 INNER JOIN Table_2 t2
    ON t1.id = t2.fk
  LEFT OUTER JOIN Table_3 t3
    ON t1.id = t3.fk;
```

INNER JOIN and a LEFT OUTER JOIN

```
SELECT *
  FROM Table_1 t1
  LEFT JOIN Table_2 t2
    ON t1.id = t2.fk
  LEFT JOIN Table_3 t3
    ON t1.id = t3.fk;
```

Two LEFT OUTER JOINS

Figure 5.60: Common SQL query expressions with joins

5.5.3 Functions and Applications

Definition (#5.5.83): In mathematics, an "application" (or "function") denoted typically f - in analysis - or A - in linear algebra - is the information of two sets, the departure set E and arrival set F (or "image of E"), and a relation associating each element x of the departure set one and only one element of the arrival set, which we name "image of x by f" in the analysis field we note that $f(x)$ or $f(E)$ to explicit the departure set. We name "images" the elements of $f(E)$ and the elements of E are named the "antecedents".

Then we say that f is an application from E to F denoted:

$$f : E \mapsto F \tag{5.5.86}$$

(remember the first arrow/sagittal diagram presented at the beginning of this section), or we also say that this is an application of arguments in E and values in F.

Remark

The term "function" is often used for applications with scalar numeric values, real or complex, that is to say when the arrival set is $\mathbb{R}$ or $\mathbb{C}$. We speak then of "real function" or "complex function". In the case of vector we prefer to use the word "application" as we already mention it in the definition.

✍**Example:**

Consider the following arbitrary function:

$$f(\vec{x},\vec{p},\vec{d}) = \sum_{i=1}^{n} \frac{p_i x_i}{(1+d_i)^i} \tag{5.5.87}$$

with $\vec{x} \in \mathbb{R}^n$, $\vec{p} \in [0,1]^n$ and $d \in \mathbb{R}_+^n$ then the application will be written:

$$f(\vec{x},\vec{p},\vec{d}) : \mathbb{R}^n \times [0,1]^n \times \mathbb{R}_+^n \mapsto \mathbb{R} \tag{5.5.88}$$

Definitions (#5.5.84):

D1. The "graph" or "plot" (or also named "graphic" or "representative") of an application or function $f : E \mapsto F$ is the subset of the cartesian product $E \times F$ consisting of pairs $(x, f(x))$ for x varying in E. The data of the graph f determines its starting set (by projection on the first argument often denoted x) and image (projection on the second argument often denoted y).

D2. If the triplet $f(E, F, \Gamma)$ is a function where E and F are two sets and $\Gamma \subset (E \times F)$ is a graph, E and F are the source and purpose of f respectively. The "definition domain" or "departure set" of f is:

$$D_f = I = \{x \in E \mid \exists y \in F, (x, y) \in \Gamma\} \tag{5.5.89}$$

D3. Given three non empty sets E, F, G, any function of $E \times F$ to G is named a "composition law" of $E \times F$ with values in G.

D4. An "internal composition law" (or simply "internal law") in E is a composition law of $E \times E$ with values in E (that is to say this is the case $E = F = G$).

Remark

The subtraction in $\mathbb{N}$ is not an internal composition law although it is part of the four basic high-school arithmetic operators. But the addition in $\mathbb{N}$ is such an internal law.

D5. An "external composition law" (or simply "external law") in E is a composition law of $F \times E$ with values in E, where F is a separate set of E. In general, F is a set, named "scalar set".

✍**Example:**

In the case of a vector space (see definition much lower) the multiplication of a vector (whose components are based on a given set) by a real scalar is an example of external composition law.

Remark

An external composition law with values in E is also named "action of F on E". The set F is then the field operators. They also say that F operates on E (keep in mind the example of the vectors mentioned above).

D5. We name "image of f", and note $\text{Im}(f)$, the subset defined by:

$$\boxed{\text{Im}(f) = f(E) = \{y \in E \mid \exists x \in E, y = f(x)\}} \tag{5.5.90}$$

Thus, "the image" of a function $f : E \mapsto F$ is the collection of $f(x)$ for x browsing E. It is a subset of F.

And we name "ker of f", and we note $\ker(f)$, the very important subset in mathematics defined by:

$$\boxed{\ker(f) = f(\{0\}) = \{x \in E \mid f(x) = 0\}} \tag{5.5.91}$$

According to the figure (you must deeply understand this concept because we will reuse the ker many times to prove theorems that have important practical applications later in various chapters):

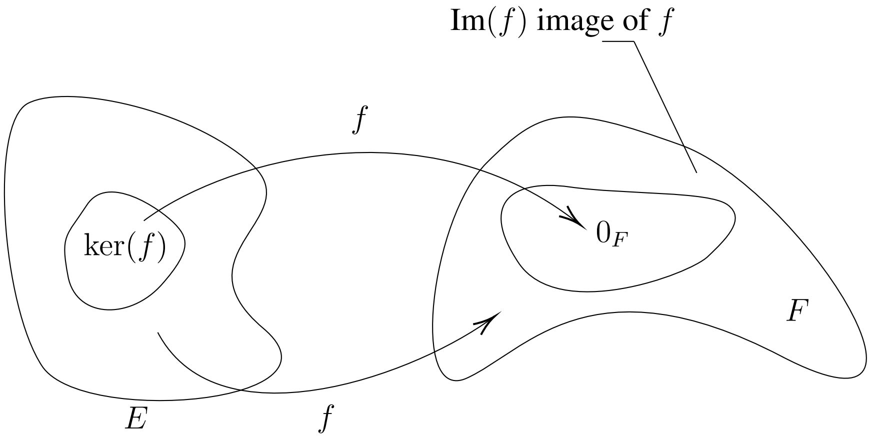

Figure 5.61: **ker concept of a function**

Remarks

R1. $\ker(f)$ is derived from the German "Kern", simply meaning "kernel".

R2. Note that $\ker(f) \subset \ker\left(f^2\right)$ because $f(x) = 0$ implies $f(f(x)) = 0$ (and same for any power n of f^n). It follows that $\ker(f) = \ker\left(f^n\right)$ (i.e. $\ker(f^m) = \ker(f^{m+1})$).

R3. Normally the notations Im and ker are reserved for group homomorphisms, rings, fields and to linear applications between vector spaces and modules, etc. (see further below). We do not usually use them for any applications between any sets. But ... it does not really matter for the moment at this level of the book.

✍**Examples:**

E1. The sine function has from its argument a kernel that is $\ker(\sin(x)) = 2\pi\mathbb{Z}$.

E2. We want to determine the kernel of the matrix:

$$A = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 3 & 3 \end{bmatrix} \tag{5.5.92}$$

For this purpose we transform the matrix into the following system:

$$\begin{cases} x + 2y + 4z = 0 \\ 2x + 3y + 3z = 0 \end{cases} \tag{5.5.93}$$

Simplifying, we get:

$$\begin{cases} x + 2y + 4z = 0 \\ \quad - y - 5z = 0 \end{cases} \tag{5.5.94}$$

Hence:

$$\begin{cases} x - 6z = 0 \\ y + 5z = 0 \end{cases} \tag{5.5.95}$$

Finally:

$$\ker(A)=\{(6z,-5z,z)\mid z\in\mathbb{R}\}=\begin{pmatrix}6\\-5\\1\end{pmatrix} \tag{5.5.96}$$

Applications and functions can have a phenomenal amount of properties. Below you can find some easy one that are part of the general knowledge of the physicist (for more information about what a function is, see the section on Functional Analysis page 2170).

Let f be an application or function of a set E to a set F then we have the following properties:

P1. An application or function is said to be "surjective" if:

Any element y of F is the image by f of at least (we emphasize on the "at least") an element of E. We thus say that it is a "surjection" from E to F. It follows from this definition, that an application or function $f:E\mapsto F$ is surjective and denoted:

$$\boxed{f:E\twoheadrightarrow F} \tag{5.5.97}$$

if and only if $F=\text{Im}f$. In other words, we also write this definition as following:

$$\forall y\in F,\exists x\in E:\quad y=f(x) \tag{5.5.98}$$

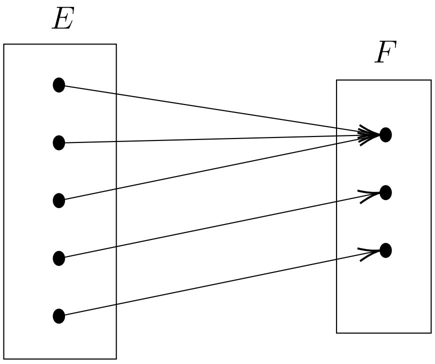

Figure 5.62: **Schematic representation of a surjective application or function**

P2. An application or function is said to be "injective" if:

Any element y of F is the image by f of at most (we emphasize the "at most") a single element of E. We thus say that f is an injection of E to F. It follows from this definition, that an application or function $f:E\mapsto F$ is injective and denoted:

$$\boxed{f:E\rightarrowtail F} \tag{5.5.99}$$

if and only if the relations $x_1,x_2\in E$ and $f(x_1)=f(x_2)$ involve. In other words: an application or function for which two separate elements have distinct images is say to be "injective". Or an application or function is injective at least if one of the following equivalent properties holds:

P2.1 $\forall x,y \in E^2: \; f(x)=f(y) \Rightarrow x=y$

P2.2 $\forall x,y: \; x \neq y \Rightarrow f(x) \neq f(y)$

P2.3 $\forall y \in F$ the equation in x, $y=f(x)$ has at least one solution in E

All this can be resumed by:

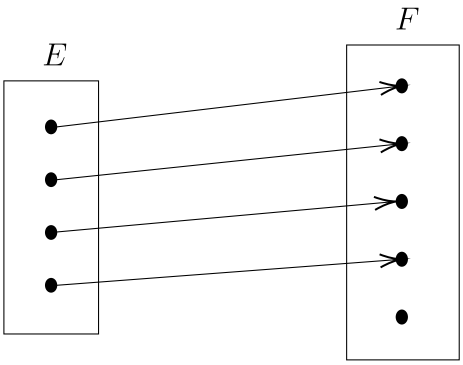

Figure 5.63: **Schematic representation of an injective application or function**

P3. An application or function is said to be "bijective" or "total application/function" if:

An application or function f from E to F is both injective and surjective. In this case, we have that for any element y of F, the equation $y=f(x)$ admits in E a single (not "at least" or not "at most") pre-image x and denoted:

$$\boxed{f: E \leftrightarrow F} \tag{5.5.100}$$

In other words, we also write this definition as following:

$$\forall y \in F, \exists ! x \in E: \quad y=f(x) \tag{5.5.101}$$

This is illustrated by:

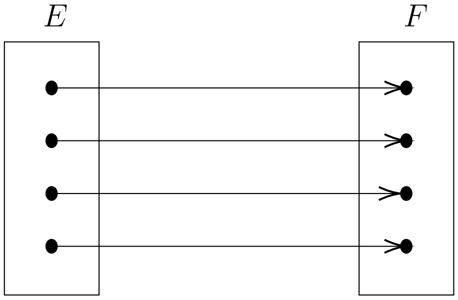

Figure 5.64: **Schematic representation of a bijective application or function**

We are thus naturally led to define a new application from F to E, named "inverse function" or "reciprocal function" of f and denoted f^{-1} (some authors and teachers use the notation ${}^r f$ instead...) that to every element of F matches the unique pre-image element x of E (also named sometimes "solution") of the equation $y=f(x)$. In other words:

$$x=f^{-1}(y) \tag{5.5.102}$$

The existence of an inverse (reciprocal) function or application implies that the graph of a bijective function or application (in the set of real numbers...) and that of its inverse (reciprocal) are symmetric with respect to the right of equation $y = x$.

Indeed, we notice that if $y = f(x)$ is equivalent to $x = f^{-1}(y)$, then these equations imply that the point (x, y) is on the graph of f if and only if the point (y, x) is the graph of equation f^{-1}.

As we can see for example in the figure below with the sinus function (see section Trigonometry page 2503):

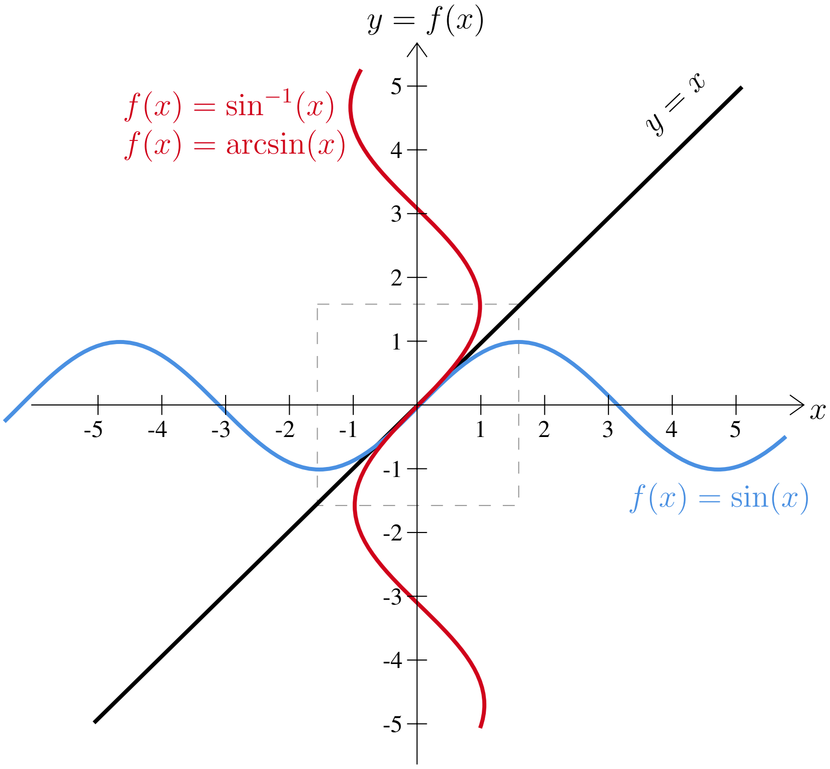

Figure 5.65: **Bijective function example**

✍**Example:**

Take the case of a holiday station where a group of tourists must be housed in a hotel. Each way to allocate these tourists in hotel rooms may be represented by an application of all tourists to all the rooms (to each tourist is assigned a room).

- Tourists want the application to be injective, that is to say, each of them has a single room. This is only possible if the number of tourists does not exceed the number of rooms.
- The hotel manager hopes that the application is surjective, that is to say, each room is occupied. This is only possible if there are at least as many tourists than rooms.
- If it is possible to spread the tourists so that there is only one per room, and all the rooms are occupied: the application will then be both injective and surjective that is to say bijective.

Remarks

R1. It comes from the definitions above that f is bijective in the set of real numbers if and only if any horizontal line intersects the graph of the function at a single point. This leads us to the second following remark:

R2. An application that satisfies the test of the horizontal line is continuously increasing or decreasing at any point in its domain.

P4. An application or function is named "composite application" or "composite function" if:

Let φ be an application or function from E to F and ψ an application or function of F in G. The application or function that associates to each element x of the set E an element $\psi(\varphi(x))$ of G is named "composed application" of φ and ψ and is denoted by:

$$\psi \circ \varphi \tag{5.5.103}$$

where the symbol "$\circ$" is named "round" (do not confused with the scalar product we will see later in the section of Vector Calculus at page 1821!). Thus, the above relation is written "psi round phi" but has to be read "phi round psi" (...). So:

$$\boxed{(\psi \circ \varphi)(x) = \psi(\varphi(x))} \tag{5.5.104}$$

Let, moreover, χ be an application (not a function!) of G in H. We check immediately that the composition operation is associative for applications (for more details see the section of Linear Algebra page 1947):

$$\chi \circ (\psi \circ \varphi) = (\chi \circ \psi) \circ \varphi \tag{5.5.105}$$

This allows us to omit parentheses and write more simply:

$$\chi \circ \psi \circ \varphi \tag{5.5.106}$$

In the particular case where φ would be an application or function from E to E, we note φ^k the composed application $\varphi \circ \varphi \circ \ldots \circ \varphi$ (k times).

What's important in what we have seen until now in this section is that all defined properties listed above are applicable to numbers' sets.

Let us see a concrete and very powerful example:

5.5.3.1 Cantor-Bernstein Theorem

Caution!! This theorem, for which the result may seem trivial, is not necessarily easy to approach (its mathematical formalism is not very aesthetic...). We advise you to read the proof slowly and imagine the sagittal diagrams in your head during the developments.

Here is the hypothesis to prove:

Theorem 5.30. Let X and Y be two sets. If there is an injection (remember the definition of an injective function or application above) from X to Y and another from Y to X, then both sets are in bijection (remember the definition of a bijective function or application above). It is therefore an antisymmetric relation.

This is illustrated by:

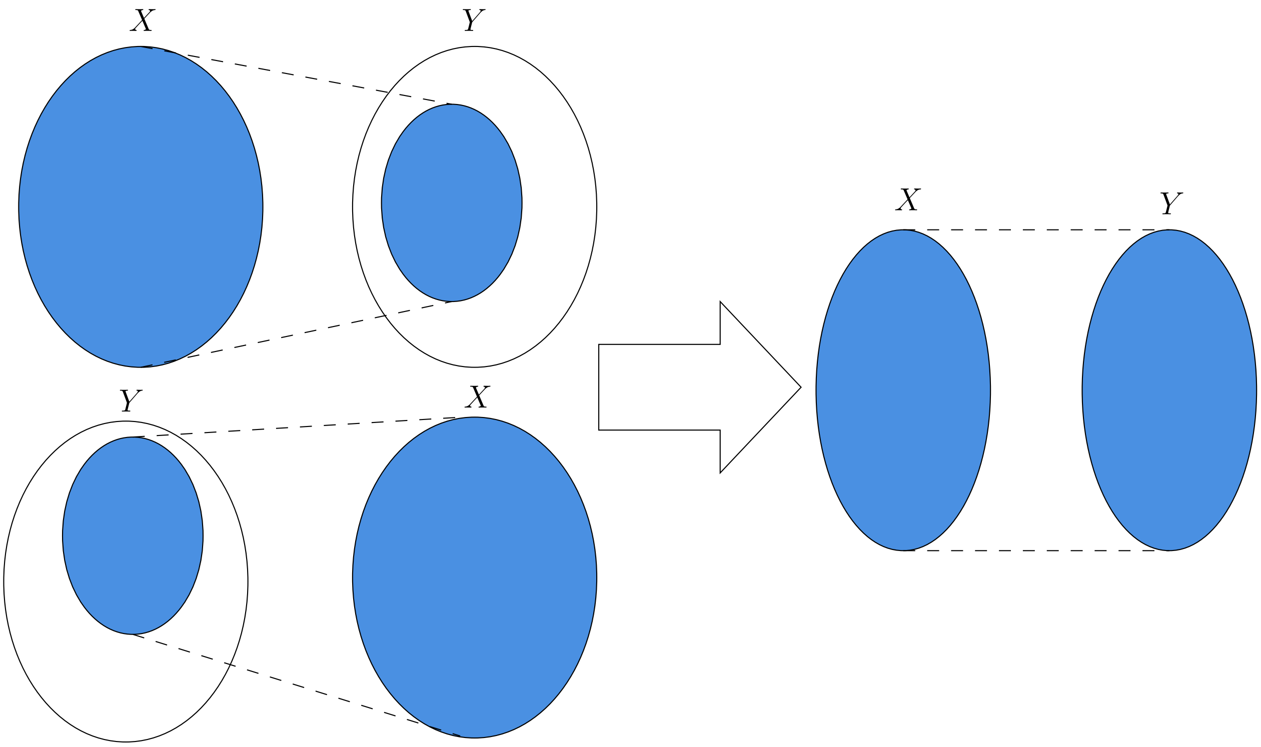

Figure 5.66: **Representation of an antisymmetric relation**

Formally this theorem is sometimes written:

$$\text{Card}(Y) \leq \text{Card}(X) \quad \text{and} \quad \text{Card}(X) \leq \text{Card}(Y) \Leftrightarrow \text{Card}(X) = \text{Card}(Y) \tag{5.5.107}$$

or more technically:

$$(X \rightarrowtail Y) \wedge (Y \rightarrowtail X) \Leftrightarrow X \leftrightarrow Y \tag{5.5.108}$$

For the proof we need rigorously to demonstrate beforehand a lemma (intuitively obvious... but not formally) who's statement is as follows:

Lemma 5.30.1. Let X, Y, Z three sets such that $X \subseteq Z \subseteq Y$. If X and Y are in bijection through a function f, then X and Z are in bijection through a function g.

Technically, we write this:

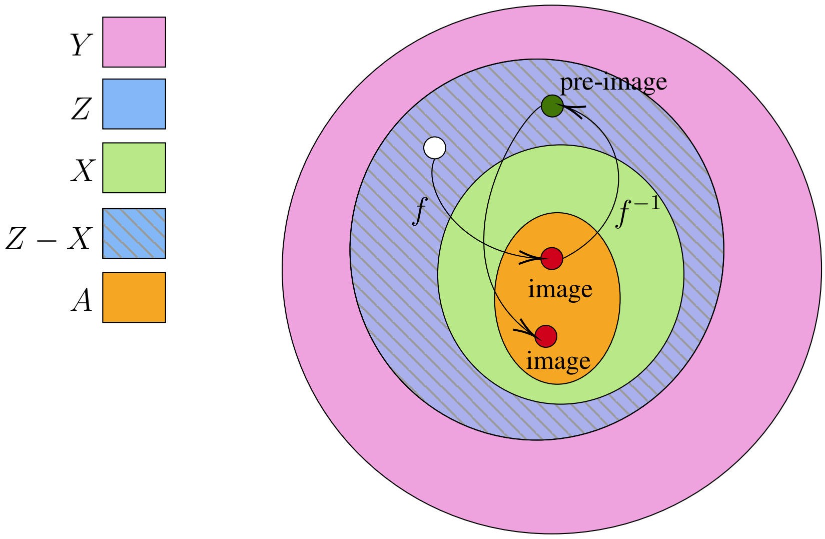
$$\left.\begin{array}{l} X \subseteq Z \subseteq Y \\ f : X \leftrightarrow Y \end{array}\right\} g : X \leftrightarrow Z \tag{5.5.109}$$

An example of application of this lemma is the set of natural numbers $\mathbb{N}$ and rational numbers $\mathbb{Q}$ which are in bijection (see the section of Number Theory page 225 for the proof). Therefore, all the rational numbers are in bijection with the set of natural numbers since $\mathbb{N} \subseteq \mathbb{Z} \subseteq \mathbb{Q}$.

Proof 5.30.1. First, formally, we define a function f from Y to X such that it is bijective:

$$f : Y \leftrightarrow X \tag{5.5.110}$$

To continue we need a set A that will be defined by the union of the images of the functions of the functions f (of the kind $f(f(f\ldots)))$... and build such a tool is the trick of the proof!) of the pre-images of the set Z (remember that $Z \subseteq Y$) from which we exclude the elements of X (that we will be noted for this proof: $Z - X$):



In other words (if the first form is not clear...) we define the set A as the union of images of $(Z - X)$ by the applications $f \circ f \circ \ldots \circ f$. What we write in a condensed a pretty way as following:

$$A = \bigcup_{n=1}^{+\infty} f^n(Z - X) \tag{5.5.111}$$

Because $f: Y \mapsto X$ and that $(Z - X) \subseteq Y$ we have by construction $A \subseteq X$ and thus:

$$((Z-X) \cup A) \subseteq Z \tag{5.5.112}$$

Notice that we also have:

$$A = \bigcup_{n=1}^{+\infty} f^n(Z-X) \Rightarrow f(A) = f\left(\bigcup_{n=1}^{+\infty} f^n(Z-X)\right) = \bigcup_{n=1}^{+\infty} f\left(f^n(Z-X)\right) = \bigcup_{n=1}^{+\infty} f^{n+1}(Z-X) \tag{5.5.113}$$

and by reindexing:

$$f(A) = \bigcup_{n=2}^{+\infty} f^n(Z-X) \tag{5.5.114}$$

We then have (make a pattern in your head of the arrow diagrams can help at that level of the proof...) whatever A:

$$f((Z-X) \cup A) = A \tag{5.5.115}$$

We can elegantly prove this last equality as this is one of the main result (!):

$$f((Z-X) \cup A) = f(Z-X) \cup f(A) = f(Z-X) \cup \bigcup_{n=2}^{+\infty} f^n(Z-X) = \bigcup_{n=1}^{+\infty} f^n(Z-X) \tag{5.5.116}$$

Since Z can be partitioned (nothing prevents us to do this!) in two disjoint subsets (we can draw a figure on request):

$$(Z-X) \cup A \qquad \text{and} \qquad (X-A) \tag{5.5.117}$$

and without forgetting that $X \subseteq Z \subseteq Y$ and $A \subseteq X$, now we introduce as definition the function g (we don't give more information about it yet) such that:

$$g: Z \mapsto X \tag{5.5.118}$$

and for every pre-image a of g of the partition $((Z-X) \cup A) \subseteq Z$ we have:

$$\forall a \in ((Z-X) \cup A) \to f(a) \tag{5.5.119}$$

This means that because $((Z-X) \cup A) \subseteq Z$ and $Z \subseteq Y$ we can thus apply (associate) the bijective function f (remember that $f: Y \to X$) as equivalent of the function g to any element of $((Z-X) \cup A)$.

We also have also for every pre-image a of g of the partition $(X-A)$ (remember that $A \subseteq X$):

$$\forall a \in (X-A) \to a \tag{5.5.120}$$

this means that we just apply the identity function we could also associate it to g.

So to sum up, we have build a function g that is then bijective because its restrictions to the $((Z-X) \cup A)$ is f and that to $(X-A)$ is the identity which are both bijective, the first by definition, the second by construction!

Finally there exists, by construction, a bijection between X and Z and we have proved indeed, the lemma that:

$$\boxed{\left.\begin{array}{l} X \subseteq Z \subseteq Y \\ f : X \leftrightarrow Y \end{array}\right\} g : X \leftrightarrow Z} \tag{5.5.121}$$

■ Q.E.D.

Now that we have proved the Lemma let us recall the assumptions of the Cantor-Bernstein theorem using the result of the Lemma:

Consider φ an injection from X to Y and ψ an injection for Y to X with $X \subseteq Y$.

We thus have:

$$\varphi(X) \subseteq Y \qquad \text{and} \qquad \psi(Y) \subseteq X \tag{5.5.122}$$

Hence:

$$\psi(\varphi(X)) \subset \psi(Y) \subset X \tag{5.5.123}$$

Then so far we have:

- As φ is injective, then X and $\varphi(X)$ are by definition bijective (yes! indeed, an injective function is by definition bijective when we reduce its image set to the pre-image set[17])
- As ψ is injective, $\psi(\varphi(X))$ and $\varphi(X)$ are bijective.

Therefore from the previous proved lemma, X and $\psi(\varphi(X))$ are also in bijection!

By using also the lemma on $\psi(\varphi(X))$, $\psi(Y)$ and X, it follows that $\psi(\varphi(X))$ is the also in bijection with $\psi(Y)$ which gives us with what have just seen, that since $\psi(\varphi(X))$ and $\varphi(X)$ are in bijection, that $\psi(Y)$ is in bijection with $\varphi(X)$, then X and Y are indeed related by a bijective application (phew!!! it is a beautiful reasoning but it is as vicious as simple...) and we have:

$$\boxed{(X \rightarrowtail Y) \wedge (Y \rightarrowtail X) \Leftrightarrow X \leftrightarrow Y} \tag{5.5.124}$$

This theorem can obviously be interpreted in the following way: If we can count a part of a set with all the elements of another set, and vice versa, then they have the same number of elements. This is quite obvious for finished sets. The theorem above then generalizes this notion for infinite sets and this is its strength!

From there, this theorem represents one of the basic bricks to generalize the notion of set sizes to infinite sets.

---

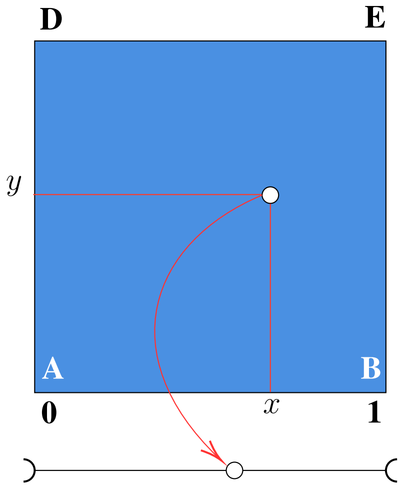
[17] but it must be notice that this work only for infinite sets!

✍**Example:**

The line is a geometric object of dimension 1, like its intervals. The plane has a dimension equal to 2. Its nature is therefore very different from that of the line. However, these two sets of points are still equipotent! In other words the open interval $]0,1[$ has the same power as the open square $]0,1[\times]0,1[$.

The only technical point to take into consideration is the following: Any real number is perfectly determined by the data of its proper decimal development.

Let a point of the open square with coordinates (x,y) with $x=0.x_0x_1x_2\ldots$ and $y=0.y_0y_1y_2\ldots$. We associate with it the point $z=0.x_0y_0x_1y_1x_2y_2\ldots$ of the open interval $]0,1[$.



The application f thus defined is clearly injective!

Let us now consider a real number z of $]0,1[$ with $z=0.z_0z_1z_2z_3z_4z_5\ldots$ This point is the image of the point of the square whose coordinates are:

$$0.z_0z_2z_4\ldots \text{ and } y=0.z_1z_3z_5\cdots$$

Surjectivity seems to follow from this.

The meticulous reader will probably show the real $0.909090\ldots$ image of the point $(0.999\ldots,0.000\ldots)$, in other words $(1,0)$ which has the notable defect of not belonging to the open square!

We have, in fact, the same problem with all numbers of the type $0.9y_09y_1\ldots$ "images" of the "segment" $\{1\}\times]0,1[$ (the "open" segment $]BC[$ in the figure above).

Our mapping f from the interval $]0,1[$ to the open square $]0,1[\times]0,1[$ is therefore injective but not surjective! It is therefore not bijective, contrary to our first expectation. In a way, this result is even more surprising than the one announced. That one can "inject" a two-dimensional object "into" and not "onto" an absolutely flat object defies all intuition! «*I see it, but I don't believe it*» in Cantor's own words.

So there is an injection of the open square into $]0,1[$.

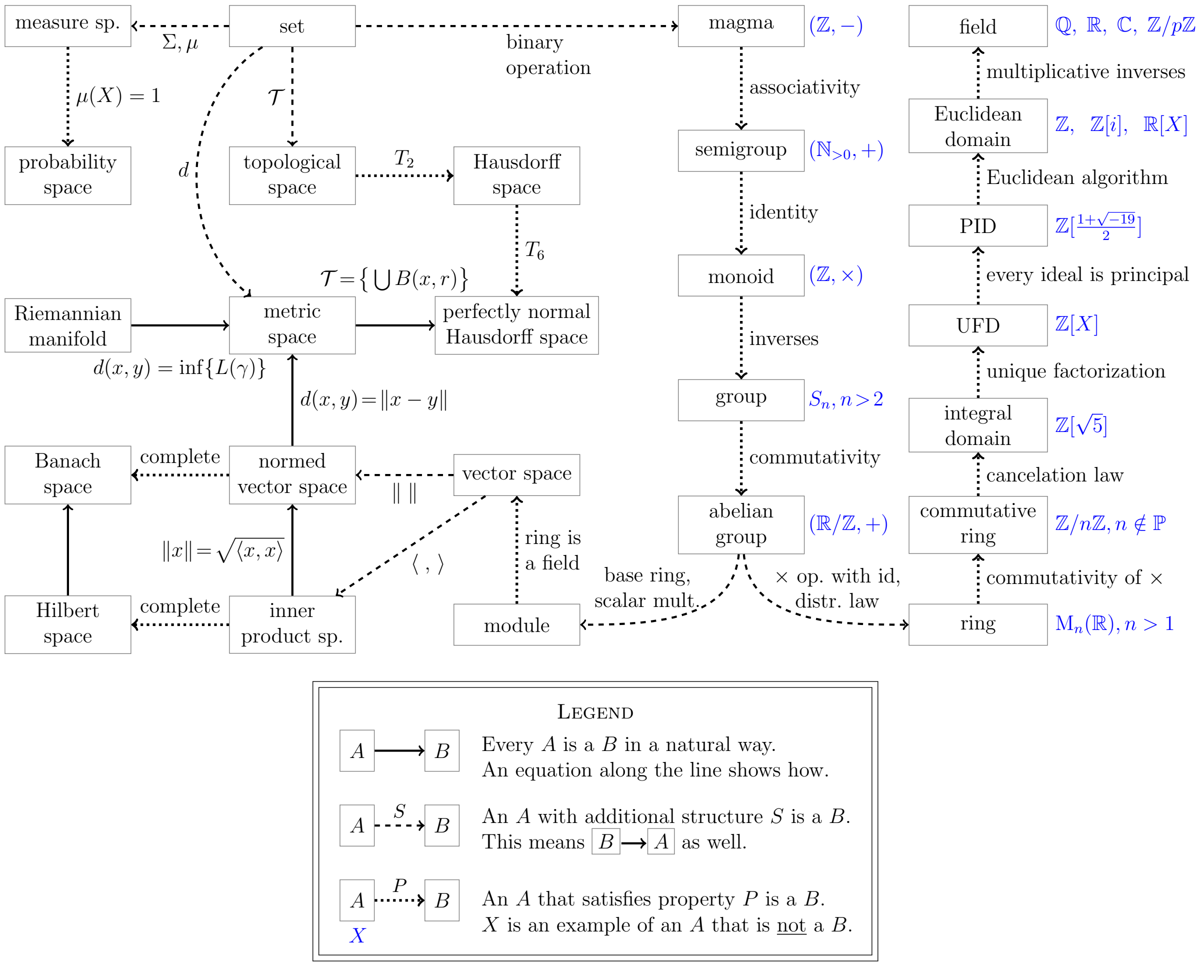
The Cantor-Berstein theorem saves the day! As we proved just before, this theorem states that if there exists an injection of X onto Y and an injection of Y onto X, then there exists a bijection from X onto Y:

$$(X \mapsto Y) \wedge (Y \mapsto X) \Leftrightarrow X \leftrightarrow Y$$

We can conclude: the open interval $]0,1[$ and the open square $]0,1[\times]0,1[$ are equipotent!

5.5.4 Structures

The so-named "modern algebra" or "abstract algebra" begins with the theory of algebraic structures due in part to Carl F. Gauss and especially to Évariste Galois. These structures exist in a very large number but only the fundamentals will interest us here (this textbook being mainly dedicated, for recall, to engineers). Before describing them, here is a synoptic diagram of these main structures and their hierarchy:



measure sp.
set
magma
$(\mathbb{Z}, -)$
field
$\mathbb{Q},\ \mathbb{R},\ \mathbb{C},\ \mathbb{Z}/p\mathbb{Z}$
Σ, μ
binary operation
$\mu(X)=1$
$\mathcal{T}$
associativity
multiplicative inverses
Euclidean domain
$\mathbb{Z},\ \mathbb{Z}[i],\ \mathbb{R}[X]$
probability space
d
topological space
T_2
Hausdorff space
semigroup
$(\mathbb{N}_{>0}, +)$
Euclidean algorithm
identity
PID
$\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$
T_6
$\mathcal{T}=\{\bigcup B(x,r)\}$
monoid
$(\mathbb{Z}, \times)$
every ideal is principal
Riemannian manifold
metric space
perfectly normal Hausdorff space
inverses
UFD
$\mathbb{Z}[X]$
$d(x,y)=\inf\{L(\gamma)\}$
unique factorization
$d(x,y)=\|x-y\|$
group
$S_n, n>2$
integral domain
$\mathbb{Z}[\sqrt{5}]$
Banach space
complete
normed vector space
vector space
commutativity
cancelation law
$\|\ \|$
abelian group
$(\mathbb{R}/\mathbb{Z}, +)$
commutative ring
$\mathbb{Z}/n\mathbb{Z}, n \notin \mathbb{P}$
$\|x\|=\sqrt{\langle x,x\rangle}$
ring is a field
$\langle\ ,\ \rangle$
base ring, scalar mult.
× op. with id, distr. law
commutativity of ×
Hilbert space
complete
inner product sp.
module
ring
$\mathrm{M}_n(\mathbb{R}), n>1$
LEGEND
A B
Every A is a B in a natural way.
An equation along the line shows how.
A S B
An A with additional structure S is a B.
This means $B \longrightarrow A$ as well.
A P B
X
An A that satisfies property P is a B.
X is an example of an A that is not a B.

Figure 5.67: **Synoptic diagram of common algebraic structures (author: ?)**

Remark

At the top of the diagram, the structure has the minimum number of constraints (exactly one), at the bottom, a maximum (to seven). The more we descend, the more specialized the structure is.

To simplify the notations, let us assume that $\star$ and $\circ$ represents a composition[18] like (like the addition, subtraction, multiplication or division, ...), then:

Definitions (#5.5.85): Given $\star$ and $\circ$ the symbols of internal laws (this could be addition and multiplication to take the best known case) to a given set E then:

---

[18] This generalized notation is sometimes named "stellar notation".

D1. $\star$ is a "commutative law" if:

$$a \star b = b \star a \tag{5.5.125}$$

D2. $\star$ is an "associative law" if:

$$a \star (b \star c) = (a \star b) \star c \tag{5.5.126}$$

D3. n is the "neutral element" for $\star$ if:

$$a \star n = n \star a = a \tag{5.5.127}$$

We will also admit without proof (it is quite intuitive) that if there is a neutral element, then it is unique.

D4. a' is the "symmetrical element" (in the general sense of the "opposite", for example for addition and "inverse" for multiplication) of a for $\star$ if:

$$a' \star a = a \star a' = n \tag{5.5.128}$$

We shall also admit, and without proof, that the symmetric of any element is unique.

D5. $\circ$ is a "distributive law" with respect to $\star$ if:

$$\begin{gathered} a \circ (b \star c) = (a \circ b) \star (a \circ c) \\ (a \star b) \circ c = (a \circ b) \star (b \circ c) \end{gathered} \tag{5.5.129}$$

D6. b is the "absorbing element" if for all a and a law $\star$ we have:

$$a \star b = 0 \tag{5.5.130}$$

Remarks

R1. If a is its own symmetric with respect to the law $\star$, mathematicians say that a is "involutive".

R2. If an element b of E satisfies:

$$a \star b = b \star a = b \tag{5.5.131}$$

then b is say to be an "absorbing element" for the law $\star$.

R3. It must always be checked that the neutral and the symmetrical elements are such on the "left" and on the "right". Thus, for example, in $(\mathbb{Z}, -)$, the element 0 is neutral to the right because $x - 0 = x$ but $0 - x = -x$.

5.5.4.1 Magma

Definition (#5.5.86): We denote a set by the term "magma M", if the components constituting it are operable with respect to an internal law $\star$:

$$(M,\star) \text{ is a magma} \Longleftrightarrow \begin{cases} \star \text{ is an operation} \\ \star \text{ is an internal law} \end{cases} \tag{5.5.132}$$

It is therefore important to remember that if we designate an algebraic structure by the term "magma", it does not mean in any case that the internal law is commutative, associative or even that it possesses a neutral element!

Remarks

R1. If, moreover, the internal law $\star$ is commutative, we speak of "commutative magma".

R2. If, moreover, the internal law $\star$ is commutative, we speak of "associative magma".

R3. If, moreover, the internal law $\star$ possesses a neutral element n, we speak sometimes of "unitary associative magma" or respectively "unitary commutative magma" but we will see just below that the both have in practice other official names.

Definition (#5.5.87): In a magma $(M,\star)$, an element x is named "regular element" (or "simplifiable element") to the left if for any pair $(a,b)\in M$ we have:

$$x\star a = x\star b \Longrightarrow a=b \tag{5.5.133}$$

Remark

We also define following the same logic a regular element to the right.

Thus, an element is say to be "regular" if it is regular to the right and to the left. If $\star$ is commutative (which is the case for a commutative magma), the notions of regular element to the left or to the right coincide.

A magma $(M,\star)$ is therefore an elementary algebraic structure. There are more subtle structures (monoids, groups, rings, fields, vector space, etc.) in which a set is provided with several laws and different properties. We will see them right now and use them throughout this textbook explicitly or implicitly.

5.5.4.2 Monoid

Definition (#5.5.88): If the law $\star$ is associative and has a neutral element n, then we say that the "unitary associative magma" is a "monoid":

$$(\ddot{M},\star)\text{ is a monoid} \quad\Longleftrightarrow\quad \begin{cases}\star\text{ is associative}\\ \exists\text{ a neutral element } n\in\ddot{M}\text{ for the law }\star\end{cases} \tag{5.5.134}$$

Remarks

R1. If the internal law $\star$ is commutative then we say that the structure forms an "abelian monoid" (or simply "commutative monoid").

R2. In some textbooks we also find that the monoid is a "semi-group" (with an associative $\star$ law!) that has a neutral element n.

Let us show immediately that the set of natural integers $\mathbb{N}$ is a totally ordered abelian monoid (as we have partially seen it in the section Operators page 288) with respect to the laws of addition and multiplication:

The addition law "+" is an internal operation such that $\forall a,b\in\mathbb{N}$ we have:

$$a+b=c \tag{5.5.135}$$

We can prove that this is indeed the case by knowing that 1 belongs to $\mathbb{N}$ such that:

$$\sum_{i=1}^{a}1+\sum_{i=1}^{b}1=\sum_{i=1}^{a+b}1 \tag{5.5.136}$$

Therefore $c\in\mathbb{N}$ and the addition is indeed an internal law (we also say that the set $\mathbb{N}$ is "stable" with respect to addition) and at the same time associative since 1 can be added to itself by definition in any order without the result being altered. If you remember that multiplication is a law that is built on addition (see section Operators page 308), then the multiplication law $\times$ is also an internal and associative law!

We will assume starting from here that it is trivial that the addition law $+$ is also commutative and that the zero "0" is the neutral element n. Thus, the multiplication law $\times$ is also commutative and it is trivial that "1" is the neutral element n.

On the other hand, to speak about something that is not directly related to the monoids... but that will be useful to us a little further below, does it exist in line with the previous example for the addition law $+$ a symmetric $\exists c$ such that $\forall a,b\in\mathbb{N}$ we have:

$$\left(\sum_{i=1}^{a}1+\sum_{i=1}^{b}1\right)+c=\left(\sum_{i=1}^{a+b}1\right)+c=0 \tag{5.5.137}$$

with $c\in\mathbb{N}$?

It is quite trivial that for this equality to be satisfied we must have:

$$\left(\sum_{i=1}^{a+b}1\right)=-c \tag{5.5.138}$$

thus:

$$a+b=-c \tag{5.5.139}$$

but negative numbers do not exist in $\mathbb{N}$. This also leads us to the conclusion that the addition law $+$ has no symmetric element in $\mathbb{N}$ and that the subtraction law $-$ does not exist in $\mathbb{N}$ (the subtraction being rigorously the addition of a number negative!).

Similarly, since it will also be useful to us a little further below, is there a symmetric a' for the multiplication law $\times$ such that $\forall a \in \mathbb{N}$ we have:

$$a' \cdot a = n = 1 \tag{5.5.140}$$

with $a' \in \mathbb{N}$?

First it is obvious that:

$$a' = \frac{1}{a} \tag{5.5.141}$$

But excepted for $a = 1$, the quotient $1/a$ does not exist in $\mathbb{N}$. Therefore we must conclude that there do not exist for any element of $\mathbb{N}$ for the multiplication law $\times$ and therefore that the division law $/$ does not exist in $\mathbb{N}$ and that the multiplication law does not form a monoid in this set .

Synthesis:

$\mathbb{N}$	$(+)$	$(-)$	$\times$	$/$
Internal operation (closure)	yes	no	yes	no
Commutative	yes		yes	
Neutral Element	yes (0)		yes (1)	
Absorbing element	no		yes (0)	
Symmetrical	no		no	

Table 5.21: **Laws and their properties in $\mathbb{N}$**

We have, for example, the following properties with respect to the set of natural integers $\mathbb{N}$ and the concept of monoid:

P1. $(\mathbb{N}, \leq, \geq)$ is completely ordered (noticed that this notation is somewhat abusive, it suffices that there is just one of the two order relations $\mathcal{R}$ so that the set is totally ordered).

P2. $(\mathbb{N}, +)$ and $(\mathbb{N}, \times)$ are abelian monoids.

P3. The element zero "0" is the absorbing element for the monoid $(\mathbb{N}, \times)$.

P4. The laws of subtraction $-$ and division $/$ do not exist in the set $\mathbb{N}$.

P5. $\mathbb{N}$ is an abelian monoid totally ordered with respect to the laws of addition $+$ and multiplication $\times$ (caution! the following notation is abusive because the monoid is composed of only one internal law and a unique order relation $\mathcal{R}$ which would give in total 4 unique monoids):

$$(\mathbb{N}, +, \leq, \geq) \tag{5.5.142}$$

Remarks

R1. It is rare to use monoids in daily work of the engineer or physicist. Indeed, this is because often when we find ourselves faced with a structure too poor to really discuss about something or develop a physical model. Then we extend it to something richer, like a group, or a field (see below) such as the set of relative integers $\mathbb{Q}$ or of real number $\mathbb{R}$ (at least...).

R2. Say that an algebraic structure is totally ordered with respect to some laws means that given a law $\star$, and $\mathcal{R}$ an order relation and a, b, c, d four elements of the structure concerned, then if $a\ \mathcal{R}\ b$ and $c\ \mathcal{R}\ d$ imply $(a\star c)\mathcal{R}(b\star d)$, we denote this structure $(S,\star,\mathcal{R})$ or simply $(S,\mathcal{R})$ and indicating the concerned law later in the text.

5.5.4.3 Groups

Definition (#5.5.89): We designate a set by the term "group", if the constituent components satisfy the three conditions of what we name the "internal group law", defined below:

$$\boxed{(G,\star)\text{ is a group}\quad\Longleftrightarrow\quad\begin{cases}\star\text{ is associative}\\ \exists\in G\text{ a neutral element for }\star\\ \forall x\in G\text{ has a symmetrical (inverse) for }\star\end{cases}}\tag{5.5.143}$$

In this case, the law of internal composition $\star$ will often (but not exclusively!) be denoted "$+$" and named "addition", the neutral element is denoted e and its value is equal to "0" and the symmetric of x is denoted "$-x$".

Let us emphasize that group structure is probably one of the most important in the practice of modern engineering and physics in general. This is why it is necessary to pay special attention to it (see section Set Algebra page 421)!

If, moreover, the internal law $\star$ is also commutative, then we say that the group is an "abelian group" or simply a "commutative group".

If there exists in G at least one element a such that every element of G is a power of$a$ or of the symmetric a' of a, we say that $(G,\star)$ is a "cyclic group of generator a" if it is finite, otherwise say that it is "monogenic" (we will come back in details on cyclic groups in the section of Set Algebra page 1418).

More generally, a group $(G,\star)$ of neutral element e, not reduced only to $\{e\}$ will be monogeneous, if there exists an element a of G distinct from e such that $G=\{e,a^1,a^2,a^3,\ldots,a^n,\ldots\}$. Such a group will be cyclic, if there exists a non-zero integer n for which $a^n=e$. The smallest non-zero integer satisfying this equality is then the "order of the group".

Let us show immediately that the set of relative integers $\mathbb{Z}$ is a totally ordered abelian group (as we have seen partially in the section Operators page 288) with respect to the laws of addition $+$ and multiplication $\times$.

First, to shorten the developments, it is useful to recall that the set $\mathbb{Z}$ is an "extension" of $\mathbb{N}$ by the fact that we have added to it all the symmetric negative sign numbers ($\mathbb{N} \subset \mathbb{Z}$).

Thus, always with the abuse of notations (because normally a group has only one law $\star$ and one order relation $\mathcal{R}$ that is sufficient to order it):

$$(\mathbb{Z}, +, -, \leq, \geq) \tag{5.5.144}$$

forms a completely ordered abelian group (4 groups by the way!) and:

$$(\mathbb{Z}, \times, \leq, \geq) \tag{5.5.145}$$

a completely ordered abelian monoid (two monoids in facts!).

Let us also notice that the law of division does not exist for any element of the set $\mathbb{Z}$! So in general we say that the division does not exist in it!

Synthesis:

$\mathbb{Z}$	$(+)$	$(-)$	$(\times)$	$(/)$
Internal operation	yes	yes	yes	no
Associativity	yes	no	yes	
Commutativity	yes	no	yes	
Neutral element	yes (0)	no (0 not neutral to the left)	yes (1)	
Absorbing element	no	no	yes (0)	
Symmetrical	yes (opposed sign)	yes	no	

Table 5.22: **Laws and their properties in $\mathbb{Z}$**

We therefore have the following properties:

P1. $(\mathbb{Z}, \leq, \geq)$ is completely ordered (caution! again this notation is a little abusive! It is enough that there is just one of the two order relation $\mathcal{R}$ so that the set is totally ordered).

P2. $(\mathbb{Z}, +)$ is a commutative group whose zero "0" is the neutral element.

P3. The division law does not exist in the set $\mathbb{Z}$.

P4. The set $\mathbb{Z}$ is an abelian group totally ordered with respect to the law of addition $+$ (caution! the following notation is again abusive because the group is composed only of one order relation $\mathcal{R}$ which would give a total of two groups):

$$(\mathbb{Z}, +, \leq, \geq) \tag{5.5.146}$$

The set $\mathbb{Z}$ set is not a commutative group totally ordered with respect to the law of multiplication:

$$(\mathbb{Z}, \times, \leq, \geq) \tag{5.5.147}$$

We see then immediately that $\mathbb{Z}$ has too restricted properties, that is why it is interesting to extend it by the set of rational $\mathbb{Q}$ defined in a very simplistic way ... by (see section Numbers page 224):

$$\mathbb{Q}=\left\{\frac{p}{q}\middle|(p,q)\in\mathbb{Z}/q=0\right\} \qquad (5.5.148)$$

This means for recall that the set of rationals $\mathbb{Q}$ is defined by the set of quotients p and q belonging each to $\mathbb{Z}$ of which we exclude to q to take the value zero (the notation $/q$ signifying for recall the "exclusion").

And we obviously have:

$$(\mathbb{N},\mathbb{Z})\subset\mathbb{Q} \qquad (5.5.149)$$

It is therefore obvious (without proof and always using the abusive notation already commented many times earlier above...) that $(\mathbb{Q},\leq,\geq)$ is also totally ordered and also that $\mathbb{Q}$ is an abelian group totally ordered with respect to the law of addition $+$ only:

$$(\mathbb{Q},+,\leq,\geq) \qquad (5.5.150)$$

What becomes interesting with $\mathbb{Q}$ is that the law of multiplication becomes an internal law and forms a commutative abelian group named "multiplicative group" with respect to $\mathbb{Q}^*$.

Proof 5.30.2. Let us prove then that the symmetric exists for the law of multiplication $\times$ such that:

$$a\times a=n=1 \qquad (5.5.151)$$

Since in $\mathbb{Q}^*$ any number can be put in the form:

$$a=\frac{p}{q} \qquad (5.5.152)$$

with $p\in\mathbb{Z}$, $q\in\mathbb{Z}^*$.

So since:

$$a'=\frac{1}{a}=\frac{1}{\left(\dfrac{p}{q}\right)}=\frac{q}{p} \qquad (5.5.153)$$

There is therefore a symmetric to every rational in $\mathbb{Q}^*$ for the law of multiplication.

■ Q.E.D.

By definition, or by construction, the division exists in $\mathbb{Q}^*$ and is an internal operation. But is it associative such that $\forall(p,q,r)\in\mathbb{Q}^*$ we have:

$$\frac{\dfrac{p}{q}}{r}=\frac{p}{\dfrac{q}{r}} \qquad (5.5.154)$$

In fact, the verification is fairly trivial if we remember that division is defined from the law of multiplication of the inverse and that the latter law is... associative! So it comes:

$$\frac{\frac{p}{q}}{r}=\left(p\frac{1}{q}\right)\frac{1}{r}=p\left(\frac{1}{q}\frac{1}{r}\right)=p\left(\frac{1}{qr}\right)\neq\frac{p}{\frac{q}{r}}=\frac{p}{q\frac{1}{r}}=p\frac{r}{q} \tag{5.5.155}$$

We can also ask ourselves the division law $(/)$ is commutative such that the relation:

$$\frac{a}{b}=\frac{b}{a} \tag{5.5.156}$$

with $\forall(a,b)\in\mathbb{Q}^*$.

We see very well that this is not the case since we can write this last relation in the form:

$$\frac{a}{b}=\frac{b}{a}=\pm 1\Rightarrow a=\pm b \tag{5.5.157}$$

To sum up:

$\mathbb{Q}$	$(+)$	$(-)$	$(\times)$	$(/)$
Internal law	yes	yes	yes	yes
Associativity	yes	no	yes	no
Commutativity	yes	no	yes	no
Neutral element	yes (0)	no (0 not neutral to the left)	yes (1)	yes (1 neutral to the right)
Absorbing element	no	no	yes (0)	yes (0 at the numerator)
Symmetrical	yes (opposed sign)	yes (opposed sign)	no (excepted in $\mathbb{Q}^*$)	no

Table 5.23: **Laws and their properties in $\mathbb{Q}$**

We therefore have the following properties:

P1. $(\mathbb{Q},\leq,\geq)$ is totally ordered

P2. $(\mathbb{Q},+),(\mathbb{Q}^*,\times)$ are independently totally ordered abelian groups

P3. Zero "0" is the absorbent element with respect to the group $(\mathbb{Q}^*,\times)$

P4. The set $\mathbb{Q}$ is an abelian group totally ordered with respect to the laws of addition and multiplication that we denote:

$$(\mathbb{Q},+,\leq,\geq)\qquad\text{and}\qquad(\mathbb{Q}^*,\times,\leq,\geq) \tag{5.5.158}$$

The same properties are applicable to $\mathbb{R}$ and $\mathbb{C}$ but with the difference that the latter are not orderable.

However, it may be understandable that for $\mathbb{C}$ the reader is sceptical. Let us develop all this:

We must make sure that the sum "+", the difference "$-$", the product "$\times$" and the quotient "$/$" of two numbers of the type $x+\mathrm{i}y$ gives something of the same type again (that is to say an application $\mathbb{C}\mapsto\mathbb{C}$).

Let us add the numbers $a+\mathrm{i}b$ and $c+\mathrm{i}d$ where a, b, c and d are real numbers:

$$\begin{aligned}&(a+\mathrm{i}b)+(c+\mathrm{i}d)\\&\quad=a+\mathrm{i}b+c+\mathrm{i}d\\&\quad=a+c+\mathrm{i}b+\mathrm{i}d\\&\quad=(a+c)+\mathrm{i}(b+d)\end{aligned}\tag{5.5.159}$$

Therefore the addition is indeed a commutative and associative internal law for which there exists a neutral and symmetric element in the set of complex numbers $\mathbb{C}$.

Let us subtracts the numbers $a+\mathrm{i}b$ and $c+\mathrm{i}d$ where a, b, c and d are here again, real numbers:

$$\begin{aligned}&(a+\mathrm{i}b)-(c+\mathrm{i}d)\\&\quad=a+\mathrm{i}b-c-\mathrm{i}d\\&\quad=a-c+\mathrm{i}b-\mathrm{i}d\\&\quad=(a-c)+\mathrm{i}(b-d)\end{aligned}\tag{5.5.160}$$

Therefore the subtraction is an internal law, but it is not commutative, neither associative it has no neutral element to the left and neither symmetric elements.

Let us now multiply the numbers $a+\mathrm{i}b$ and $c+\mathrm{i}b$ where a, b, c and d are still real numbers. To achieve our work, we use the distributivity of multiplication (see section Calculus page 1361) with respect to addition:

$$\begin{aligned}&(a+\mathrm{i}b)(c+\mathrm{i}d)\\&\quad=ac+a\mathrm{i}d+\mathrm{i}bc+\mathrm{i}b\mathrm{i}d\\&\quad=ac+\mathrm{i}ad+\mathrm{i}bc+\mathrm{i}^2bd\\&\quad=ac+\mathrm{i}ad+\mathrm{i}bc+(-1)bd\\&\quad=(ac-bd)+\mathrm{i}(ad+bc)\end{aligned}\tag{5.5.161}$$

Thus the law of multiplication is indeed a commutative, associative and distributive (!) internal operation for which there exists a neutral and symmetric element in $\mathbb{C}^*$ (see below).

A division is before all a multiplication by the inverse. Prove that there exists an inverse proves that there exists a symmetric for multiplication. Let us therefore inverse the number $x+\mathrm{i}y$ where x and y are still real numbers (different from zero!):

$$\begin{aligned}\frac{1}{x+\mathrm{i}y}&=\frac{(x-\mathrm{i}y)}{(x+\mathrm{i}y)(x-\mathrm{i}y)}\\&=\frac{x-\mathrm{i}y}{x^2-(\mathrm{i}y)^2}\\&=\frac{x-\mathrm{i}y}{x^2+y^2}\\&=\frac{x}{x^2+y^2}-\mathrm{i}\frac{y}{x^2+y^2}\end{aligned}\tag{5.5.162}$$

So the inverse of a complex number is indeed an internal non-associative and non-commutative operation for which there exists a neutral element, and it is symmetric. The same is true for division, which corresponds to the product by the inverse of a complex number.

Let us now consider quickly an example of a cyclic group (we will in-deep the subject in the section of Set Algebra page 1418): In $\mathbb{C}$, let us consider $G=\{1,\mathrm{i},-1,-\mathrm{i}\}$ equipped with the usual multiplication of complex numbers. Then $(G,\times)$ is obviously an abelian group. Such a group is also monogenic because it is generated by the powers of one of its elements: i (or $-\mathrm{i}$). This monogenic group being finite, it is then a named a "cyclic group".

5.5.4.4 Ring

The ring is the heart of the commutative algebra which is the algebraic structure corresponding to the high-school concepts of addition, subtraction, and multiplication.

Definition (#5.5.90): A commutative group (or "abelian group") A is a "ring" if it is provided with a second internal law of composition satisfying the following properties:

$$(A,+,\times) \text{ is a ring} \quad \Longleftrightarrow \quad \begin{cases} (A,+) \text{ is an abelian group} \\ \text{The law } \times \text{ is associative} \\ \text{The law } \times \text{ is distributive relatively to the law } + \end{cases} \tag{5.5.163}$$

As we already know, the neutral element of the first internal composition law "$+$" is denoted "0" and named "zero" of the ring. The second internal law $\times$ is often denoted by a mid-height point "$\cdot$" (or by a cross $\times$ in high-school) and named "multiplication".

Remarks

R1. If, moreover, the second internal law of composition "$\times$" is also commutative, the ring is say to be a "commutative ring". We also encounter non-commutative rings in which the commutativity relation is not imposed or just not necessary and then we sometimes have to impose it, then we must reinforce the property of the neutral element of this second law by imposing "1" to be a neutral element both to right and to left such that: $1a=a1=a$ (an example of a non-commutative ring is provided by the set of square $n\times n$ matrices with coefficients in a ring A, for example $M_n(\mathbb{R})$ as seen in the section of Linear Algebra page 1947).

R2. If, in addition, there exists in A a neutral element for the second internal composition law "$\times$", and that this neutral element is the unit "1" then we say that the ring is a "unitary ring" and "1" is named "unit of the ring". If the ring is commutative and has a neutral element for the second internal composition law then we speak of "commutative unitary ring".

R3. If $a\times b=0\Rightarrow(a=0 \text{ or } b=0)$, regardless of the elements a, b of A, the ring is named an "integral ring" or "ring without zero divisors" (if not, it is obviously named "non-integral ring").

R4. A "factorial ring" is a unitary and integral commutative ring in which the fundamental theorem of arithmetic (see section Number Theory page 352) is verified.

Definitions (#5.5.91):

D1. An element a of a ring A is a "unitary element" if there is a $b \in A$ such that $ab = ba = 1$. If such a b exists it is unique (we saw such an example in our study of congruence classes in the section of Number Theory page 356).

D2. An element a of a ring A is named a "left zero divisor" if there exists $x \neq 0$ such that $ax = 0$. Similarly, an element a of a ring is named a "right zero divisor" if there exists $y \neq 0$ such that $ya = 0$. An element a that is both a left AND a right zero divisor is named a "two-sided zero divisor[19]".

✍**Examples:**

E1. The only zero divisor of the ring $\mathbb{Z}$ of integers is 0.

E2. In the ring of 2×2 matrices (over any non-zero ring) we can find and a a and a non zero x as following:

$$\begin{pmatrix}1 & 1\\ 2 & 2\end{pmatrix}\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix} = \begin{pmatrix}-2 & 1\\ -2 & 1\end{pmatrix}\begin{pmatrix}1 & 1\\ 2 & 2\end{pmatrix} = \begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix} \tag{5.5.164}$$

In the latter example it is difficult to choose which of the matrix is the "zero divisor" this is why we can find in some textbooks that a AND x are considered as "zero divisors".

Remarks

R1. It should be obvious from the preceding relations that clear that a ring is integral if and only if it has no zero divisors (excepted the 0 as already mentioned earlier!).

R2. The concepts of unit and zero divisor are incompatible but one element of a ring can be neither. This is the case, for example, of all integers different from $\{0, -1, 1\}$ in $\mathbb{Z}$. These are neither units nor divisors from zero! We name them "regular elements".

We will see an important example of ring in the context of our study of polynomials (see section Calculus page 1368), but we have already seen some very important ones in our study of congruence classes in the section of Number Theory page 356.

Let's see some examples of rings! During our study of groups earlier above, we have seen that the structures:

$$(\mathbb{Z},+) \qquad (\mathbb{Q},+) \qquad (\mathbb{R},+) \qquad (\mathbb{C},+) \tag{5.5.165}$$

are all four abelian groups and the first three are in addition totally ordered.

---

[19] If the ring is commutative, then the left and right zero divisors are obviously the same.

Since the law of division is in no way associative, we can restrict ourselves to studying for each of the above groups the pair of laws: "$+$" and "$\times$".

So it comes very quickly that:

$$(\mathbb{Z},+,\times) \qquad (\mathbb{Q},+,\times) \qquad (\mathbb{R},+,\times) \qquad (\mathbb{C},+,\times) \tag{5.5.166}$$

constitute unitary and integral commutative rings.

Remark

We will consider as obvious, at this level of our discourse, that the reader will have noticed that $\mathbb{Z}$ is a "sub-ring" of $\mathbb{Q}$ in the sense that the operations defined are internal to each set and that the neutral and identity elements are identical and that there exists for each element of these sets an opposite which is in the same set. We will deepen the concept of "sub-ring" a little further.

Let A be a ring. We have the following properties:

P1. $a+b=a+c \Rightarrow (b=c) \qquad \forall a,b,c \in A$

Proof 5.30.3. This derives from the definition D4 seen at the beginning of the part concerning the algebraic structures (every element has an opposite / symmetric). Indeed, we can add to:

$$a+b=a+c \tag{5.5.167}$$

the element $-a$. We then get:

$$(-a)+a+b=(-a)+a+c \tag{5.5.168}$$

by the existence of the opposite this gives:

$$0+b=0+c \tag{5.5.169}$$

hence:

$$b=c \tag{5.5.170}$$

■ Q.E.D.

P2. $0\cdot a=0 \qquad \forall a\in A$

Proof 5.30.4. This property derives from the definitions D3 (existence of the neutral element), and D4 (existence of the opposite / symmetric), and D5 (distributivity with respect to the other law) and finally of property P1 above. Indeed, we have:

$$0\cdot a+a=0\cdot a+1\cdot a=(0+1)\cdot a=1\cdot a=0a \tag{5.5.171}$$

We therefore have:

$$0\cdot a+a=a \tag{5.5.172}$$

The property P1 above allows us to conclude that:

$$0\cdot a=0 \tag{5.5.173}$$

(we could discuss the relevance of this kind of proof...).

■ Q.E.D.

P3. $(-1)\cdot a=-a \qquad \forall a\in A$

Proof 5.30.5. This property is proved using P2. We have:

$$0=0\cdot a=(1+(-1))\cdot a=1\cdot a+(-1)\cdot a \tag{5.5.174}$$

by adding $-a$ to this last equality, we get:

$$(-a)=(-1)\cdot a \tag{5.5.175}$$

■ Q.E.D.

5.5.4.4.1 Sub-ring

Definitions (#5.5.92): Given A a ring and $S\subset A$ a subset of A. We say that S is a "sub-ring" of A if:

P1. $n\in S$ (the neutral element of A is also that of S)

P2. $a\in S\Rightarrow -a\in S$

P3. $(a,b)\in S\Rightarrow a+b\in S$

P4. $(a,b)\in S\Rightarrow a\cdot b\in S$

✍**Example:**

The ring $\mathbb{Z}$ is a sub-ring of $\mathbb{Q}$ and $\mathbb{R}$.

5.5.4.5 Field

Definition (#5.5.93): We denote a set of numbers by the term "field" if:

$$\boxed{(F,+,\times)\text{ is a field if }\quad\Longleftrightarrow\quad\begin{cases}(F,+,\times)\text{ is a unitary ring}\\(F-\{0\},\times)\text{ is a group}\end{cases}} \tag{5.5.176}$$

Hence a field is a non-zero ring in which any non-zero element is invertible or in other words: a ring of which all non-zero elements are unit elements is a field.

Remarks

R1. If the internal law × is also commutative, the field is obviously named a "commutative field".

R2. The quaternions (see section Numbers page 261) form a "non-commutative field" for addition and multiplication.

Let us see examples of field among the following unitary rings:

$$(\mathbb{Z},+,\times)\qquad(\mathbb{Q},+,\times)\qquad(\mathbb{R},+,\times)\qquad(\mathbb{C},+,\times)\tag{5.5.177}$$

We must first determine which ones do not constitute groups with respect to the internal law of multiplication "$\times$".

As we have already seen in our study of the groups earlier above, it is evident that we must eliminate $(\mathbb{Z},+,\times)$ because of the existence of inverses which is not assured in this set.

Thus, the fundamental fields of arithmetic are:

$$(\mathbb{Q},+,\times)\qquad(\mathbb{R},+,\times)\qquad(\mathbb{C},+,\times)\tag{5.5.178}$$

and since the law of multiplication "$\times$" is commutative in these sets, we can affirm that these fields are also commutative fields.

We often have in the small classes the following diagram for the most important field used by students, engineers and managers:

$$\underset{\text{commutative field totally ordered}}{(\mathbb{R},+,\times)}\left\{\begin{array}{l}\underset{\text{commutative field}}{(\mathbb{R},+)}\left\{\begin{array}{l}\underset{\text{commutative group}}{(\mathbb{R},+)}\left\{\begin{array}{l}\text{The addition is an internal law}\\\text{The addition is an internal associative law}\\\text{The addition is a commutative law}\\\text{There exist a neutral element for the additon: }0\\\text{Any real number has an opposite}\end{array}\right.\\\underset{\text{commutative group}}{(\mathbb{R},\times)}\left\{\begin{array}{l}\text{The multiplication is an internal law}\\\text{The multiplication is an internal associative law}\\\text{The multiplication is an internal commutative law}\\\text{There exist a neutral element for the multiplication: }1\\\text{Every real number has an inverse}\end{array}\right.\\\text{The multiplication is distributive relatively to the addition}\end{array}\right.\\\underset{\text{totally ordered set}}{(\mathbb{R},\leq)}\left\{\begin{array}{l}\text{The relation }\leq\text{ is reflexive}\\\text{The relation }\leq\text{ is antisymmetric}\\\text{The relation }\leq\text{ is transitive}\end{array}\right.\end{array}\right.\tag{5.5.179}$$

Thus, we named "Field" a set F of real or complex numbers a such that the sum, difference, product and quotient of any two of these numbers a belong to the same system F.

We also state this property in the following way: the numbers of a field reproduce by the rational operations (addition, subtraction, multiplication, division). Thus it is evident that the number zero can never form the denominator of a quotient and the set of integers can not form a field because the division in the set of integers does not necessarily give a numerical value that exist in this same set.

5.5.4.6 Vector Spaces

When we define a "vector" (see section Vector Calculus page 1797), we usually refer in high-school to an "Euclidean space" (see also the section Vector Calculus) of n dimensions denoted $\mathbb{R}^n$. However, the notion of vector space is much more larger as we will see by reading the other sections and chapters of this textbook than the latter which represents only one particular case.

Definition (#5.5.94): A "vector space (EV)" or "K-vector space" (abbreviated sometimes: K-ev) on the field K (we will frequently take and use for this field $\mathbb{R}$ or $\mathbb{C}$) is a set $(E,+,\cdot)$ have the following properties:

$$\boxed{(E,+,\cdot)\quad\Longleftrightarrow\quad\begin{cases}(E,+)\text{ is an abelian group}\\ \cdot\text{ is an external law defined by }\begin{cases}\cdot:E\times K\mapsto E\\(x,a)\to a\cdot x\end{cases}\end{cases}}\tag{5.5.180}$$

We thus have two composition laws (taking the traditional notations of the vectors which will perhaps be more intuitive and useful for the reader and for what will also follow...):

1. An internal law of composition: the addition denoted "+" which satisfies:
   1.1. Associativity:
   $$\forall\vec{x},\vec{y}\vec{z}\in E:\quad(\vec{x}+\vec{y})+\vec{z}=\vec{x}+(\vec{y}+\vec{z})\tag{5.5.181}$$
   1.2. Commutativity:
   $$\forall\vec{x},\vec{y}\in E:\quad\vec{x}+\vec{y}=\vec{y}+\vec{x}\tag{5.5.182}$$
   1.3. Neutral element:
   $$\exists\vec{0}\in E:\quad\forall\vec{x}\in E,\vec{x}+\vec{0}+\vec{x}\tag{5.5.183}$$
   1.4. Opposite element:
   $$\forall\vec{x}\in E,\exists\vec{x}'\in E:\quad\vec{x}+\vec{x}'=\vec{0}\tag{5.5.184}$$
2. An external composition law: the multiplication by a scalar, denoted "$\cdot$" (to avoid the confusion with the cross product "×" that we will introduce in the section of Vector Calculus page 1830), which satisfies:
   2.1. Associativity:
   $$\forall\lambda,\mu\in K,\forall\vec{x}\in E:\quad\lambda\cdot(\mu\cdot\vec{x})=(\lambda\cdot\mu)\cdot\vec{x}\tag{5.5.185}$$
   2.2. Distributivity on the right with respect to the field K:
   $$\forall\lambda,\mu\in K,\forall\vec{x}\in E:\quad(\lambda+\mu)\cdot\vec{x}=\lambda\cdot\vec{x}+\mu\cdot\vec{x}\tag{5.5.186}$$
   2.3. Left distributivity with respect to E:
   $$\forall\lambda\in K,\forall\vec{x},\vec{y}\in E:\quad\lambda\cdot(\vec{x}+\vec{y})=\lambda\cdot\vec{x}+\lambda\cdot\vec{y}\tag{5.5.187}$$

2.4. Neutral element (from K to E):

$$\forall \vec{x} \in E: \quad 1 \cdot \vec{x} = \vec{x} \tag{5.5.188}$$

Hence 10 properties at the total (yes indeed... the fact of having an internal or external law is a property on itself!).

We then say that the vector space has a "vectorial algebraic structure" and that these elements are "vectors" (at least in the most common case...), the elements of K are the "scalars" (see section Numbers page 209).

Remarks

R1. The respective internal laws that are frequently used as addition and multiplication that we already know very well on $\mathbb{R}$, which is very convenient for our habits...

R2. From now on, to distinguish the elements of the field K from the set E, we shall denote those of K by Greek letters and those of E by Latin capital letters.

It is should not be necessary to prove that these properties are satisfied for $\mathbb{R}^n$ and consequently for $\mathbb{R}^2$. We can, however, ask ourselves some subsets of $\mathbb{R}^n$?

✍**Examples:**

E1. Let us consider the rectangular region of $\mathbb{R}^3$ shown in figure (a) and in perspective in the (c) below:

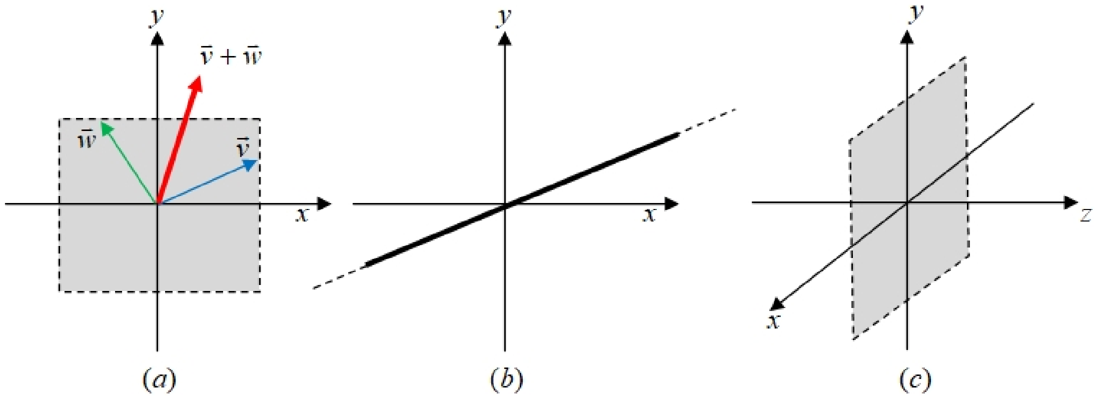


Figure 5.68: **Example of a concept of vector space**

This subset (the rectangle) of $\mathbb{R}^2$ is not a vector space because, among other things, the internal operation property (closure) of the abelian group is not satisfied. Indeed, if we take two vectors $\vec{v}$,$\vec{w}$ inside the rectangle and add them, the result $\vec{v}+\vec{w}$ may come out of the rectangle. On the other hand, it is easy to see that the (infinite) line $\mathbb{R}^1$ illustrated in figure (b) follows all the properties enumerated above and, consequently, defines a vector space. Let us notice, however, that this line must pass through the origin, otherwise the property of the neutral element of the abelian group would not be respected (the neutral element then would no longer exists).

E2. Another example of a vector space is the "polynomial vector space" with real coefficients of degree two or less denoted $\mathcal{P}^2$ (see section Calculus page 1368). For example, two randomly chosen elements of this space are:

$$\begin{aligned} x &= t^2+2t+3 \\ y &= -t+5 \end{aligned} \tag{5.5.189}$$

This polynomial set respects the properties of a vector space. Indeed, if we add two polynomials of degree two or less, we get another polynomial of degree two or less. We can also multiply a polynomial by a scalar without changing the order (or degree) of that latter, and so on.... We can therefore represent a polynomial by vectors whose terms are the coefficients of the polynomial.

Let us notice that we can also form vector spaces with sets of functions more general than polynomials. It is only important to respect the 10 fundamental properties of a vector space!

So defined, a vector space E on K is an action of $(K,\times)$ on $(E,+)$ which is compatible with the group law (by extension an "automorphism" - see definition below - on $(E,+)$).

Definition (#5.5.95): Let E be a vector space, we name "vectorial subspace" F of E a subset of E if and only if (as written by nice mathematicians...):

$$\begin{aligned} &F \neq \varnothing \\ &\forall (X,Y): \quad \in F^2, X+Y \in F \\ &\forall \lambda \in K, \forall X \in F: \quad \lambda X \in F \end{aligned} \tag{5.5.190}$$

or by using another notation (the one used more by physicists and engineers):

$$\begin{aligned} &F \neq \varnothing \\ &\forall (\vec{x},\vec{y}) \in F^2: \quad \vec{x}+\vec{y} \in F \\ &\forall \lambda \in K, \forall \vec{x} \in F: \quad \lambda \vec{x} \in F \end{aligned} \tag{5.5.191}$$

5.5.4.7 C-algebra A

Definition (#5.5.96): A "C-algebra A" where C is a commutative field (also named sometimes "K-algebra A" where the K state for "Körper" in German) is a set A with two internal composition laws: the addition "$+$" and the cross product "$\times$" and one external law (multiplication) "$\cdot$" with operator domain C (multiplication by a scalar) if and only if:

$$(A,C,+,\cdot,\times) \text{ is a } C\text{-algebra} \quad \Longleftrightarrow \quad \begin{cases} (A,+,\cdot) \text{ is a } C\text{-vector space} \\ (A,+,\times) \text{ is a unitary ring} \\ \forall \lambda \in C, \forall a,b \in A: \quad (\lambda a)\cdot b = a \cdot (\lambda b) = \lambda (a \cdot b) \end{cases} \tag{5.5.192}$$

✍**Examples:**

E1. To take an example in the line of the one on vector space examples, the Euclidean space $\mathbb{R}^3$ with the addition "$+$", the multiplication "$\cdot$" and the cross product "$\times$" is a non-associative and non-commutative $\mathbb{R}$-algebra denoted $(\mathbb{R}^3, \mathbb{R}, +, \cdot, \times)$.

E2. The set $\mathbb{C}$ is an $\mathbb{R}$-algebra (as complex numbers can be seen as a vector with two components according to what we saw in the section Numbers page 244).

5.5.4.8 Summary

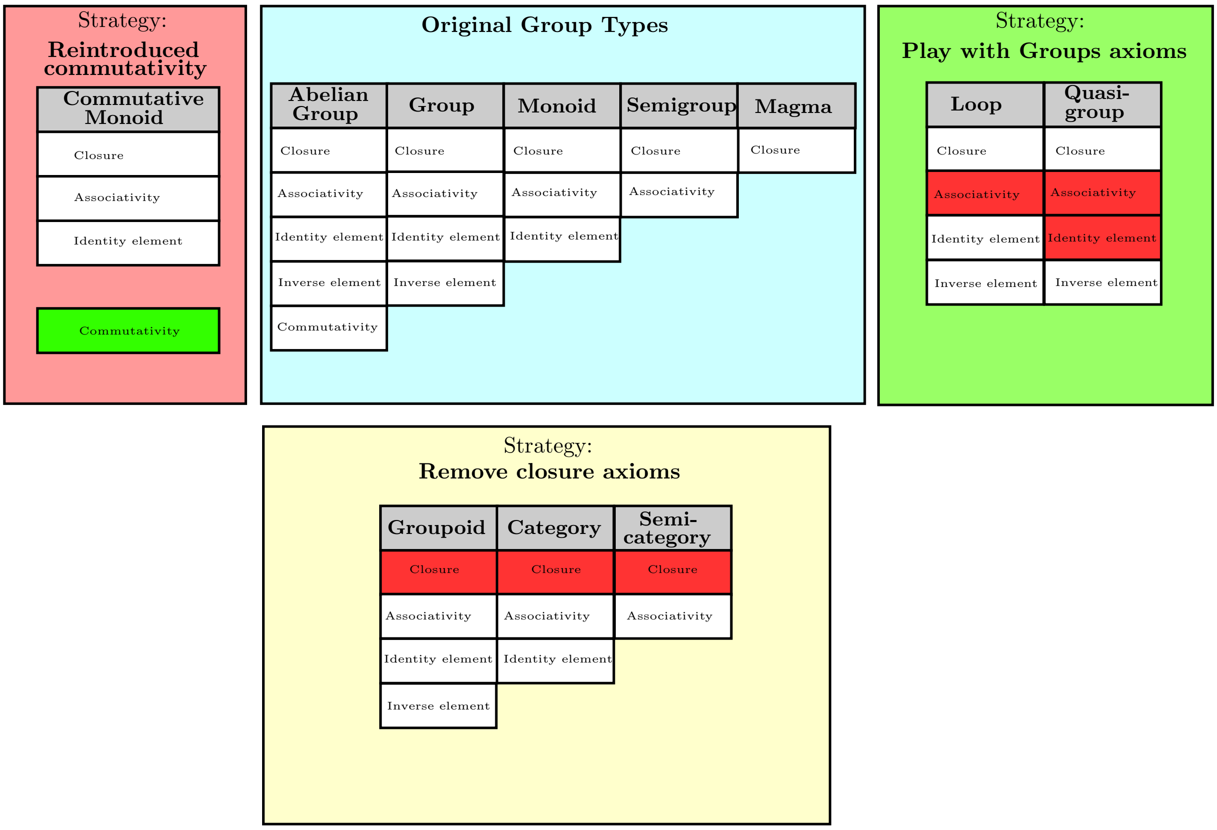
Ok... so far a lot of definitions and concepts. To sum up the most important algebraic structures seen so far we get the authorization of Kevin Binz to reproduce very nice visual figures that could help the reader brain to have an overview of most important concepts seen so far.

So first let us introduce the different set structures in the point of view where we build them by adding each time a new property:

Magma	**Semigroup**	**Monoid**	**Group**	**Abelian Group**
Closure	Closure	Closure	Closure	Closure
	Associativity	Associativity	Associativity	Associativity
		Identity element	Identity element	Identity element
			Inverse element	Inverse element
				Commutativity

Table 5.24: Summary of most common algebraic structures
(source: `https://kevinbinz.com/tag/identity-element/`, author: Kevin Binz)

Of course, there is no particularly strong reason to "knife" axioms in this order. More esoteric options are available (in the below, red axioms are removed, green are re-introduced) introducing at the same time some set structure that we did not introduce before:



Strategy:
Reintroduced commutativity

Commutative Monoid
Closure
Associativity
Identity element
Commutativity

Original Group Types

Abelian Group	**Group**	**Monoid**	**Semigroup**	**Magma**
Closure	Closure	Closure	Closure	Closure
Associativity	Associativity	Associativity	Associativity	
Identity element	Identity element	Identity element		
Inverse element	Inverse element			
Commutativity				

Strategy:
Play with Groups axioms

Loop	**Quasi-group**
Closure	Closure
Associativity	Associativity
Identity element	Identity element
Inverse element	Inverse element

Strategy:
Remove closure axioms

Groupoid	**Category**	**Semi-category**
Closure	Closure	Closure
Associativity	Associativity	Associativity
Identity element	Identity element	
Inverse element		

Figure 5.69: Summary of most common algebraic structures
(source: `https://kevinbinz.com/tag/identity-element/`, author: Kevin Binz)

Closure: For all a, b in S, $a + b$ is also in S

Associativity: For all a, b, c in S, the relation $(a + b) + c = a + (b + c)$ holds

Identity element: There exists the element 0 such that for each a in S, $0 + a = a + 0 = a$ holds.

Inverse element: For each a in S, there exists an element $-a$ such that $a + (-a) = -a + a = 0$

Commutativity: For all a, b in S, the relation $a + b = b + a$ holds.

Figure 5.70: Group Theory addition summary
(source: https://kevinbinz.com/tag/identity-element/, author: Kevin Binz)

If we think of the above as a function, three inputs are relevant to us: the target set, the operator, and the identity element. Thus, we can condense the above into $(S, +, 0)$.

Closure: For all a, b in S, $a \times b$ is also in S

Associativity: For all a, b, c in S, the relation $(a \times b) \times c = a \times (b \times c)$ holds

Identity element: There exists the element 1 such that for each a in S, $1 \times a = a \times 1 = a$ holds.

Inverse element: For each a in S, there exists an element $1/a$ such that $a \times (1/a) = 1/a \times a = 1$

Commutativity: For all a, b in S, the relation $a \times b = b \times a$ holds.

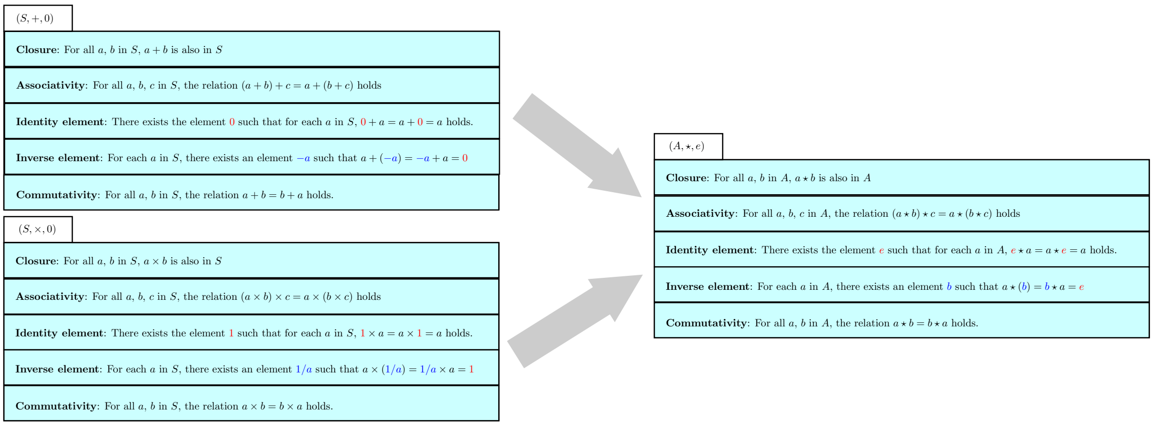
Figure 5.71: Group Theory multiplication summary
(source: https://kevinbinz.com/tag/identity-element/, author: Kevin Binz)

If we think of the above as a function, three inputs are relevant to us: the target set, the operator, and the identity element. Thus, we can condense the above into $(S, \times, 0)$.

Did the above two sections feel painfully similar? Yes it seems!

One lesson they teach you in computer science is: if you notice yourself copy-pasting code, you should try to consolidate your software into one function.

Analogously, we can generalize addition and multiplication, like this:



$(S, +, 0)$

Closure: For all a, b in S, $a + b$ is also in S

Associativity: For all a, b, c in S, the relation $(a + b) + c = a + (b + c)$ holds

Identity element: There exists the element 0 such that for each a in S, $0 + a = a + 0 = a$ holds.

Inverse element: For each a in S, there exists an element $-a$ such that $a + (-a) = -a + a = 0$

Commutativity: For all a, b in S, the relation $a + b = b + a$ holds.

$(S, \times, 0)$

Closure: For all a, b in S, $a \times b$ is also in S

Associativity: For all a, b, c in S, the relation $(a \times b) \times c = a \times (b \times c)$ holds

Identity element: There exists the element 1 such that for each a in S, $1 \times a = a \times 1 = a$ holds.

Inverse element: For each a in S, there exists an element $1/a$ such that $a \times (1/a) = 1/a \times a = 1$

Commutativity: For all a, b in S, the relation $a \times b = b \times a$ holds.

$(A, \star, e)$

Closure: For all a, b in A, $a \star b$ is also in A

Associativity: For all a, b, c in A, the relation $(a \star b) \star c = a \star (b \star c)$ holds

Identity element: There exists the element e such that for each a in A, $e \star a = a \star e = a$ holds.

Inverse element: For each a in A, there exists an element b such that $a \star (b) = b \star a = e$

Commutativity: For all a, b in A, the relation $a \star b = b \star a$ holds.

Figure 5.72: Merging of addition and multiplication
(source: https://kevinbinz.com/tag/identity-element/, author: Kevin Binz)

Here, we generalize our three inputs defined above:

- S becomes a specific instance of an input set
- $+$ and $\times$ become specific instances of a general class of operator.
- 0 and 1 become specific instances of a general class of identity elements.

We have seen earlier that this particular set of five axioms is an "Abelian group" (also known as a "commutative group") that can be summarized as:

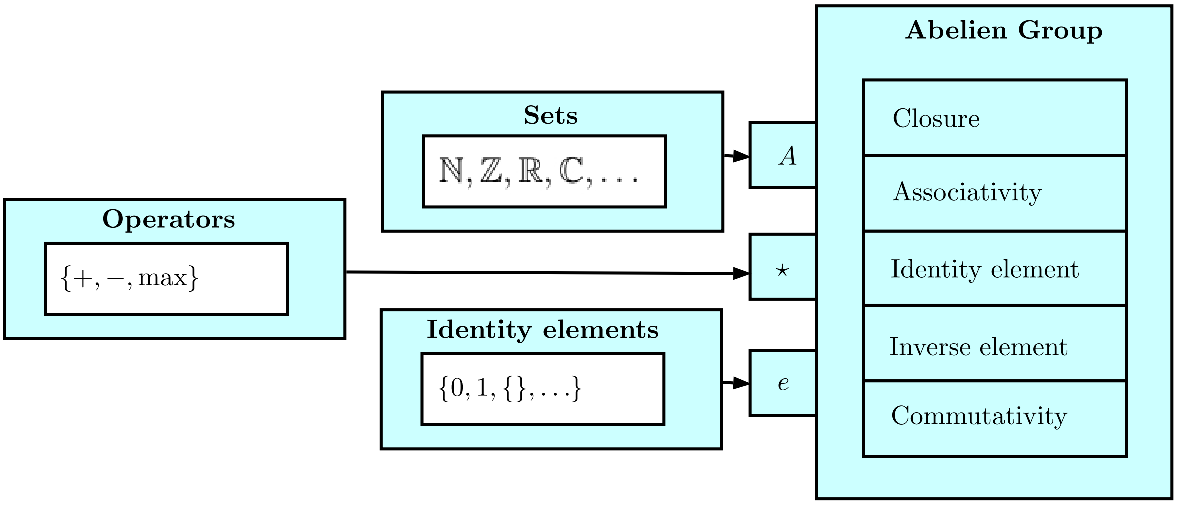


Figure 5.73: Abelian group structure (source: https://kevinbinz.com/tag/identity-element/, author: Kevin Binz)

Let us marry addition-groups and multiplication-groups together, into a field:

Field $(F,+,0,\times,1)$	
Closure: For all a, b in F, $a+b$ is also in F	Abelian Group $F(+,0)$
Associativity: For all a, b, c in F, the relation $(a+b)+c=a+(b+c)$ holds	
Identity element: There exists the element 0 such that for each a in F, $0+a=a+0=a$ holds.	
Inverse element: For each a in F, there exists an element $-a$ such that $a+(-a)=-a+a=0$	
Commutativity: For all a, b in F, the relation $a+b=b+a$ holds.	
Closure: For all a, b in F, $a\times b$ is also in F	Abelian Group $(F-\{0\},\times,1)$
Associativity: For all a, b, c in F, the relation $(a\times b)\times c=a\times(b\times c)$ holds	
Identity element: There exists the element 1 such that for each a in F, $1\times a=a\times 1=a$ holds.	
Inverse element: For each a in F, there exists an element $1/a$ such that $a\times(1/a)=1/a\times a=1$	
Commutativity: For all a, b in F, the relation $a\times b=b\times a$ holds.	
Left distributivity: For all a, b, c in F, the equation $a\times(b+c)=(a\times b)+(a\times c)$ holds	Relations between "$+$" and "$\times$"
Right distributivity: For all a, b, c in F, the equation $(a+b)\times c=(a\times c)+(b\times c)$ holds	

Figure 5.74: Field set structure (source: `https://kevinbinz.com/tag/identity-element/`, author: Kevin Binz)

5.5.5 Morphisms

In many fields of mathematics, morphism refers to a structure-preserving map from one mathematical structure to another. The notion of morphism recurs in much of contemporary mathematics. In set theory, morphisms are functions; in linear algebra, linear transformations; in group theory, group homomorphisms; in topology, continuous functions, and so on.

The concept of homomorphisms (from the Greek homoios = similar and morphê = form) was defined by mathematicians because it makes it possible to highlight remarkable properties of functions in particular with their structures, their kernel, and what we name the "ideals" (see further below). They will allow us to identify one algebraic structure of another.

Definitions (#5.5.97):

D1. If $(A,\star)$ and $(B,\circ)$ are two magmas (regardless of the notation used for internal laws), an application f of A into B is a named "homomorphism of magma" or "morphism of magma" (by abuse of language we sometimes write just "homomorphism") if:

$$\boxed{f(a\star b)=f(a)\circ f(b)\quad \forall a,b\in A} \tag{5.5.193}$$

In other words: if the image of a composition in A is the composition of the images in B.

D2. If $(A,\star)$ and $(B,\circ)$ are two monoids, an application f of A into B is a "homomorphism of monoid" if:

$$\boxed{\begin{aligned} f(a\star b)&=f(a)\circ f(b)\quad \forall a,b\in A\\ f(1_A)&=1_B \end{aligned}} \tag{5.5.194}$$

where 1_A, 1_B are the respective neutral elements of the monoids A, B.

D3. If A, B are two rings, a "homomorphism of rings" (very important for the Cryptography section of this textbook page 7216!) of A in B is a function $f:A\mapsto B$ such that for any $a,a'\in A$ we have:

$$\boxed{\begin{aligned} f(1_A)&=1_B\\ f(a+a')&=f(a)+f(a')\\ f(a\cdot a')&=f(a)f(a') \end{aligned}} \tag{5.5.195}$$

where 1_A, 1_B are the neutral elements of the rings A, B with respect to the multiplication "$\cdot$".

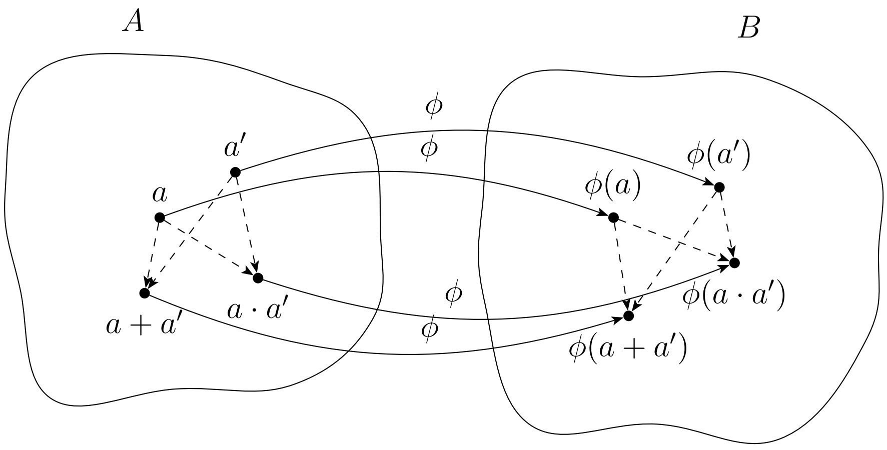

Figure 5.75: **Ring homomorphism**

Given $f : A \mapsto B$ a homomorphism of rings. Then:

P1. $f(0) = 0$

Proof 5.30.6. By:

$$f(a + a') = f(a) + f(a') \tag{5.5.196}$$

we have

$$f(a + 0) = f(a) + f(0) \tag{5.5.197}$$

By adding $-f(a)$ on both sides of the equality, we get:

$$0 = f(0) \tag{5.5.198}$$

■ Q.E.D.

P2. $f(-a) = -f(a)$

Proof 5.30.7. This property also follows from:

$$f(a + a') = f(a) + f(a') \tag{5.5.199}$$

and of the property P1. Indeed, we have:

$$f(0) = f(a + (-a)) = f(a) + f(-a) = 0 \tag{5.5.200}$$

By adding $-f(a)$ to the two sides of the last equality, we get:

$$f(-a) = -f(a) \tag{5.5.201}$$

■ Q.E.D.

P3. If a is a unit of A, then $f(a)$ is a unit of B and $f(a)^{-1} = f(a^{-1})$.

Proof 5.30.8. Given $a, b \in A$ such that:

$$ab = ba = 1 \tag{5.5.202}$$

Then by $f(a \cdot b) = f(a) \cdot f(b)$ and $f(1_A) = 1_B$, we have:

$$1 = f(1) = f(ab) = f(a)f(b) \tag{5.5.203}$$

and also:

$$1 = f(b)f(a) \tag{5.5.204}$$

which shows that $f(b)$ is the inverse of $f(a)$ if b is the inverse of a.

■ Q.E.D.

Let us now introduce a quite powerful theorem:

Theorem 5.31. Let us now show that a homomorphism of rings $f : A \mapsto B$ is injective if and only if the element 0 is the only pre-image of 0 (and therefore reciprocally), which is technically written:

$$\ker(f) = \{0\} \tag{5.5.205}$$

That is to say: the kernel is "trivial".

Proof 5.31.1. The condition is clearly necessary. Let us show that it is sufficient:

We therefore assume that $\ker(f) = 0$. Given $a, a' \in A$ such that $f(a) = f(a')$. Then as we have a homomorphism of ring we can write:

$$0 = f(a) - f(a') = f(a - a') \tag{5.5.206}$$

Which implies that $a - a' = 0$ and therefore that $a = a'$.

This shows that f is injective if it is a homomorphism and that $\ker(f) = 0$ is indeed a sufficient condition.

■ Q.E.D.

D4. Given $(A, +)$ and $(B, \star)$, two groups and f an application $f : A \mapsto B$. We say that f is a "homomorphism of group" if (we could just as well put the "$\star$" instead of the "$+$" in the first group and the "$+$" instead of the "$\star$" in the second group, the definition would remain the same by simply replacing the respective operators !):

$$\boxed{\begin{gathered} f(x + y) = f(x) \star f(y) \quad \forall x, y \in A \\ f(1_A) = 1_B \\ f(x^{-1}) = (f(x))^{-1} \quad \forall x \in A \end{gathered}} \tag{5.5.207}$$

where 1_A, 1_B are the respective neutral elements of the groups A, B. We notice that the only difference between a homomorphism of rings and a homomorphism of groups is that it has two laws instead of one and that we add the concept of inverse.

That said, the third proposition above is in fact a consequence of the definition composed only of the first two lines. Indeed, consider a homomorphism f between the groups $(A, +)$ and $(B, \star)$ with 1_A and 1_B respectively the neutral elements of A and B, then we have:

$$\forall x \in A : \quad 1_B = f(1_A) = f(x + x^{-1}) = f(x) \star f(x^{-1}) \tag{5.5.208}$$

Hence:

$$\forall x \in A: \quad 1_B = f(x) \star f(x^{-1}) \tag{5.5.209}$$

Therefore:

$$\forall x \in A: \quad f(x) = \frac{1_B}{f(x^{-1})} = (f(x^{-1}))^{-1} \tag{5.5.210}$$

✍**Example:**

The exponential function e (see section Functional Analysis page 2289) and the logarithm function $\ln$ are a group homorphism of the group $(\mathbb{R}^+, +)$ on the group $(\mathbb{R}^+, \cdot)$.

D5. Let f be an application $f: A \mapsto B$ from one field to another. We say that f is a "homomorphism of field" if f is a homomorphism of ring...

Indeed, the fact that the homomorphism of field is the same as that of a ring is due to the fact that the difference between the two structures is that the elements of the field are all invertible (no law or law property differs between the both according to their definition of the homomorphism).

Let us show now that every homomorphism of field is injective ("injective homomorphism") by remembering that earlier above we have proved that every homomorphism of rings was injective!

Proof 5.31.2. If a is different from 0 and $b = a^{-1}$ (we use here the property that the elements of a field are invertible!) then:

$$1 = f(1) = f(a \cdot b) = f(a) \cdot f(b) \tag{5.5.211}$$

So when a is different from zero, $f(a)$ is also different from 0 which proves that $\ker(f) = \{0\}$ and therefore that f is injective.

■ Q.E.D.

D6. Given A and B be two K-vector spaces and $f: A \mapsto B$ an application of A into B. We say that f is a "linear mapping" or "linear application" or "homomorphism of vector spaces" (it is implicit that this is relative to the indicated laws and for the chosen application) if:

$$\begin{aligned} &f(x+y) = f(x) + f(y) \quad \forall (x,y) \in A \\ &f(\lambda x) = \lambda f(x) \quad \forall x \in A, \forall \lambda \in K \end{aligned} \tag{5.5.212}$$

and we denote by $L(A, B)$ the set of linear applications.

Remarks

R1. We have already defined the concept of linear application but did not specify that the two sets A and B were K-vector spaces.

R2. A linear application is named a "linear form" if and only if $B = K$.

D7. If the homomorphism is bijective we will say that f is an "isomorphism". If there is an isomorphism between A and B, we say that A and B are "isomorphic" and we will denote this $A \simeq B$.

Remark

The isomorphism allows the identification of two sets with an identical algebraic structure (group, ring, etc.) but whose elements are named in a different way.

D8. If the homomorphism f is a purely internal mapping, then we will say that f is an "endomorphism" (in other words, we have an endomorphism if in the definition of the homomorphism we have $A = B$).

Remark

If we have an endomorphism f of E, then f is then restricted to $\Im(f)$. So the term "endomorphism" just means that the application f arrives in E and not that it touches all the elements of E itself. We have then $f(E) \subset E$ and not necessarily $f(E) = E$ because in the latter case we say that f is surjective as we have already seen it.

D9. If the endomorphism f is furthermore bijective (hence in other words if the homomorphism is an endomorphism and an isomorphism), then we will say that f is an "automorphism".

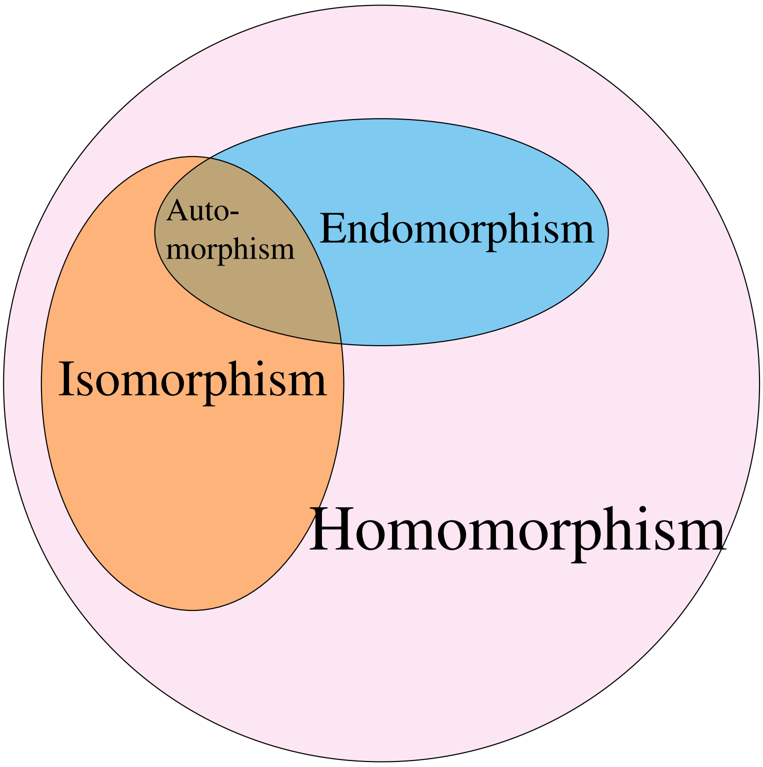

Figure 5.76: **Venn diagram of different types of homomorphisms (source: Wikipedia, author: Martin Thoma)**

5.5.5.1 Ideal

Definition (#5.5.98): Let A be a commutative ring (like $(\mathbb{R},+,\cdot)$ for example). A subset $S \subset A$ is an "ideal" if:

P1. For all $a, a' \in S$:

$$a + a' \in S \qquad (5.5.213)$$

P2. For all $a \in S$ and all $r \in A$:

$$r \cdot a \in S \qquad (5.5.214)$$

In other words, an ideal is a closed subset for addition and stable for the multiplication by any element of A.

✍**Example:**

The set of even numbers $\mathbb{Z}_{2k}$ is an example of ideal of the set of relative integers $\mathbb{Z}$.

Remark

The ideals $S = \{0\}$ and $S = A$ are named the "trivial ideals".

To know if an ideal is equal to the whole ring, it is useful to use the following property which specifies that if A is a ring and I an ideal of A, then if $1 \in A$ we have $I = A$.

Proof 5.31.3. This results from the property P2 of the definition of an ideal:

For any $r \in A$, we have $r = r \cdot 1 \in 1$ because $1 \in I$.

■ Q.E.D.

Another quite general example of ideal is given by the kernel of a homomorphism of rings. Indeed, let us prove that the kernel of a homomorphism $F : R \mapsto S$ is an ideal of R.

Proof 5.31.4. Given $a, a' \in \ker(f)$. Then:

$$f(a + a') = f(a) + f(a') = 0 + 0 = 0 \qquad (5.5.215)$$

which shows that $a + a' \in \ker(f)$. Given $r \in R$, then:

$$f(ra) = f(r)f(a) = f(r) \cdot 0 = 0 \qquad (5.5.216)$$

Which shows that $r \cdot a \in \ker(f)$.

■ Q.E.D.

Proposition: Let A be a ring and let $a \in A$. The subset:

$$\{ax|x \in A\} \tag{5.5.217}$$

Denoted (a) or aA, is an ideal (we will see a concrete example after the next small set of definitions).

Definitions (#5.5.99):

D1. An ideal $I \neq A$ of a ring A is named a "principal ideal" if there exists $a \in A$ such as $I = (a)$.

D2. A ring of which all the ideals are principal is named "principal ring".

✍**Example:**

Let us now show that the ring $\mathbb{Z}$ is principal (because all its ideals are principal).

Let I be an ideal of $\mathbb{Z}$ (it is easy to choose one: for example, all multiples of 2 or 3, etc.). Let $r \in I$ be the smallest non-zero positive integer of I. We will show that $I = r\mathbb{Z} = (r)$.

Let a be any element of I. The Euclidean division allows us to write:

$$a = qr + r' \tag{5.5.218}$$

with $0 \leq r' < r$ (as we have already proveed it).

But as $r' = a - qr$ and that $a, r \in I$, by the definition of an ideal, we have $r' \in I$ (the sum or difference of the elements of an ideal belonging to the ideal). By the choice of r (r' being less than r) this implies that $r' = 0$ and therefore that $a = rq$.

Thus every element of I is a multiple r of q:

$$I = r\mathbb{Z} \tag{5.5.219}$$

So for the set of even number (denoted as we know $2\mathbb{Z}$ or $\mathbb{Z}_{2k}$) we have:

$$I_{2\mathbb{Z}} = 2 \cdot \mathbb{Z} \tag{5.5.220}$$

The example above uses only the Euclidean division on $\mathbb{Z}$. We can then generalize this result to the rings which possess a Euclidean division. Thus, for example, the ring $K[X]$ of the polynomials (see section Calculus page 1368) with coefficients in a field K is a principal ring because it has an Euclidean division.

Theorem 5.32. The ring $K[X]$ of the polynomials with coefficients in a field K is a principal ring (all its ideal are principal).

Proof 5.32.1. Let I be an ideal of $K[X]$. Let us denote by d the smallest degree that can have a non-zero polynomial of I. If $d = 0$ then $1 \in I$ and therefore $I = 1 \cdot K[X] = K[X]$. Otherwise, given $a(X)$ a polynomial of degree d. If $u(X) \in I$ then one can divide $u(X)$ by $a(X)$. There exists therefore $q(X), r(X) \in K[X]$ such as $\deg(r) < \deg(a) = d$ and:

$$u(X) = q(X) \cdot a(X) + r(X) \tag{5.5.221}$$

Therefore $r(X) \in I$ which lead to $r = 0$ (otherwise contradiction with the minimality of d). Therefore:

$$u(X) = q(X) \cdot a(X) \tag{5.5.222}$$

We have just shown that:

$$I = a(X) \cdot K[X] \tag{5.5.223}$$

■ Q.E.D.

To come back on $\mathbb{Z}$... we have then proved that the only ideals are those of the form $r\mathbb{Z}$. Moreover if we have d and r which are integers > 1. Then $r\mathbb{Z} \subset d\mathbb{Z}$ if and only if $d|r$.

Proof 5.32.2. If $d|r$ then there exists n with $r = d \cdot n$. Let $m \cdot a$ be an element of $r\mathbb{Z}$. Therefore:

$$r \cdot a = d \cdot n \cdot a \in d\mathbb{Z} \tag{5.5.224}$$

which shows that $r\mathbb{Z} \subset d\mathbb{Z}$.

Conversely, if $r \in d\mathbb{Z}$ this implies that r is of the form $d \cdot n$ and this proves that d divides r.

■ Q.E.D.

Theorem 5.33. Let us also prove that a ring R is a field if and only if it possesses only the trivial ideals:

$$I = \{\{0\}, R\} \tag{5.5.225}$$

Proof 5.33.1. Let us show that the condition is necessary: Let I be a non-zero ideal of R (that is so say different of $\{0\}$) and $r \in I$ a non-zero element. By hypothesis (that it is a field), it is invertible, that is to say that there exists $t \in R$ such that:

$$r \cdot t = t \cdot r = 1 \tag{5.5.226}$$

This implies that $1 \in I$ and therefore, by a result obtained earlier above $I = R$.

Conversely, suppose that every ideal $I \neq R$ is the null ideal (that is to say $\{0\}$). Then if $r \in R$ is a non-zero element of R, the principal ideal (r) must be equal to R. But this implies that $1 \in (r)$ and therefore that there exists $x \in R$ with $r \cdot x = 1$ which shows that r is invertible. The ring R is therefore a field.

■ Q.E.D.

This characterization will enable us to quite easily prove that:

Theorem 5.34. Any homomorphism starting from a field is injective. That is, if $f : R \mapsto S$ is a homomorphism where R is a field, then f is injective.

Proof 5.34.1. We put together what has been seen so far:

- We have proved earlier above that the kernel $\ker(f)$ of a homomorphism of ring is an ideal.
- We have also proved just earlier above that set was a field if $\{0\}$ and R were the only trivial ideals.

Therefore for the both point above we have either $\ker(f) = 0$ or $\ker(f) = R$ for the field (as it encompass the concept of ring!).

But since $f(1) = 1 \neq 0$ (by definition of a homomorphism!) it follows that it remains to us only the choice $\ker(f) = \{0\}$. This implies by a previous theorem (where we have proved long time before that if $\ker(f) = \{0\}$ the homomorphism is injective) that ... f is injective.

■ Q.E.D.

Let us now study the homomorphisms whose starting ring is $\mathbb{Z}$. Let A be a ring and $f : \mathbb{Z} \mapsto A$ a homomorphism. By definition of a homomorphism and by its properties, it is necessary that as we have defined long time before that $f(0) = 0$ and $f(1) = 1$ (among others). But we also still need that:

$$f(n) = \underbrace{f(1 + \ldots + 1)}_{\text{k}} = \underbrace{(1_A + \ldots + 1_A)}_{\text{k}} = n \cdot 1_A \quad (5.5.227)$$

for any $k \in \mathbb{Z}$. Thus f is completely determined by the information of $f(1)$ and is therefore unique.

Conversely, we show that the application $f : \mathbb{Z} \mapsto A$ defined by:

$$f(k) = k \cdot 1_A \quad (5.5.228)$$

is a homomorphism of rings. In summary, there exists one and only one homomorphism of $\mathbb{Z}$ in any ring A.

Definition (#5.5.100): Given R a ring and $f : \mathbb{Z} \mapsto R$ the unique homomorphism defined just previously. If f is injective, we say that R is of "zero characteristic" and we denote it:

$$\text{char}(R) = k = 0 \quad (5.5.229)$$

Otherwise, $\ker(f)$ is a non trivial ideal of $\mathbb{Z}$ and as $\mathbb{Z}$ is therefore principal (as we have demonstrated above) it is of the form $k\mathbb{Z}$ with $k > 0$. The integer k is named the "characteristic of R" and we have therefore:

$$\text{char}(R) = k > 0 \quad (5.5.230)$$

Remark

Less formally, the characteristic of a A ring is the smallest positive integer k such that $k \cdot 1_A = 0$. If there is none, then the characteristic is zero.

The definition above may not be very clear (at least for me it is not!). So let us see another approach to introduce the characteristic much more detailed...:

Given R a ring and any of its elements r, let us denote integers with boldface type. So **1** is the integer number one, for instance, **0** is the integer zero, whereas 0_R and 1_R are the neutral elements in R.

Since R under addition is an abelian group, we can as usual define:

$$\mathbf{0}r = 0_R \qquad \text{and} \qquad (\boldsymbol{n}+\mathbf{1})r = \boldsymbol{n}r + r \tag{5.5.231}$$

By definition of a homomorphism, we have if $f : \mathbb{Z} \mapsto R$ that:

$$f(\boldsymbol{n}) = \boldsymbol{n}1_R \tag{5.5.232}$$

then for recall:

- $f(\boldsymbol{m}+\boldsymbol{n}) = f(\boldsymbol{m}) + f(\boldsymbol{n})$
- $f(\boldsymbol{mn}) = f(\boldsymbol{m})f(\boldsymbol{n})$
- $f(\mathbf{1}) = 1_R$

so f is a homomorphism of rings. Like all ring homomorphisms, $f : \mathbb{Z} \mapsto R$ has a kernel which is an ideal as we have proved just earlier, so we have $\ker(f) = \boldsymbol{k}\mathbb{Z}$ for a unique $\boldsymbol{k} \geq \mathbf{0}$.

If $k = 0$, then as we have proved much earlier above, then f is injective. Otherwise, we have:

$$\boldsymbol{k}1_R = 0_R \tag{5.5.233}$$

by definition of the kernel, which means that:

$$\boldsymbol{k}r = \underbrace{r + r + \ldots + r}_{\boldsymbol{k}} = \underbrace{(1_R + 1_R + \ldots + 1_R)}_{\boldsymbol{k}} r = (\boldsymbol{k}1)r = 0_R r = 0_R \tag{5.5.234}$$

for every $r \in R$. This integer $\boldsymbol{k}$ is the "characteristic" of S.

That is, char(R) is the smallest positive number $\boldsymbol{k}$ such that:

$$\underbrace{1_R + 1_R + \ldots + 1_R}_{\boldsymbol{k}\text{ times}} = 0 \tag{5.5.235}$$

if such a number $\boldsymbol{k} \in \mathbb{N}$ exists, and 0 otherwise.

✍**Examples:**

E1. The only ring that has $\text{char}(R) = 1$ such that:

$$\boldsymbol{k} \cdot 1_R = 1 \cdot 1_R = 1_R = 0_R \tag{5.5.236}$$

is the trivial ring $R = \{0_R\}$.

E2. The ring $\mathbb{Z}$ is of zero characteristic because the unique homomorphism $f : \mathbb{Z} \mapsto \mathbb{Z}$ is the identity. It is therefore injective.

E3. The injections $\mathbb{Z} \mapsto \mathbb{Q}$ and $\mathbb{Z} \mapsto \mathbb{R}$ show that $\mathbb{Q}$ and $\mathbb{R}$ (and also $\mathbb{C}$) are fields of zero characteristic.

Theorem 5.35. We now propose to prove that the characteristic of an integral ring (and in particular of a field) is equal to 0 or to a prime number p.

Proof 5.35.1. We show the contraposition. Let R be a ring of characteristic $m \neq 0$ with m not prime.

There are then natural $n, r \in \mathbb{N}$ constraint by $n, r < m$ such that $m = n \cdot r$.

Given $f : \mathbb{Z} \mapsto R$ the unique homomorphism (defined earlier above). By definition of m we have then $f(m) = 0_R$ but... (!) $f(r) \neq 0 \neq f(n)$. But then (and this it the trick of the proof!):

$$f(r)f(n) = f(r \cdot n) = f(m) = 0 \tag{5.5.237}$$

which shows that R is not integral.

■ Q.E.D.

Remark

The reciprocal of the theorem is not true as shown in the example of the ring $\mathbb{R} \times \mathbb{R}$ where addition and multiplication are made component by component. It is a ring of zero characteristic but with divisors of zero:

$$(1, 0) \cdot (0, 1) = 0 \tag{5.5.238}$$

5.6. Probabilities

PROBABILITY is the measure of the likelihood that an event will occur and therefore the calculation of probabilities handles random phenomena (known more aesthetically as "stochastic processes" when their are time-dependent), that is to say, phenomena that do not always lead to the same outcome and that can be studied using numbers their implications and occurrences. However, even if these phenomena have variable outcomes, depending on chance, we observe a certain statistical regularity.

Probability is quantified as a number between 0 and 1 (where 0 indicates impossibility and $1$indicates certainty). The higher the probability of an event, the more certain we are that the event will occur.

Probabilities are very important in practice, especially at very high management or political level. Indeed, in many cases, it is more practical to use a simple but uncertain rule rather than a complex but certain one, even if the true rule is deterministic and our modelling system has the fidelity to accommodate a complex rule. For example, the simple rule "the sales will increase" is cheap to develop and is broadly useful, while a rule of the form, "the sales will increase if the inflation index also increase, and there is no epidemia, no earthquakes, no conflict, no asteroids, no major flood, no political change, no strikes..." is expensive to develop, maintain and communicate, and after all of this effort is still very brittle and prone to failure.

The concepts related to probabilities have been given an axiomatic mathematical formalization in probability theory (see further below), which is used widely in such areas of study as mathematics, statistics, finance, gambling, science (in particular physics), artificial intelligence/Machine Learning, computer science, game theory, and philosophy to, for example, draw inferences about the expected frequency of events. Probability theory is also used to describe the underlying mechanics and regularities of complex systems.

quote
5.6:450.#38

> ❞ *We measure the degree of intelligence of an individual by the quantity of incertitudes he can handle.* ❞
>
> Emmanuel Kant

Definitions (#5.6.101): There are several ways to define a "probability". Mainly we are talking about (if we put apart the formalism of Measure Theory that we will study much later at page 2493):

D1. "Experimental or inductive probability" which is the probability derived from the whole population or a sample of the latter trough the study of the underlying phenomena with experimentation.

D2. "Theoretical or deductive probability" which is the known probability through the study of the underlying phenomenon without experimentation. It is therefore an "a priori" knowledge as opposed to the previous definition that was rather referring to a notion of "a posteriori" probability.

As it is not always possible to determine a priori probabilities, we are often asked to perform experiments. We must then be able to pass from the first to the second solution. This passage is supposed to be possible in terms of limit (with a population sample whose size approaches the size of the whole population).

The formal modelling of the probability calculus was invented by A.N Kolmogorov in a book published in 11933 (holocene calendar). This model is based on the probability space (U, A, P) that we will define a little further and that we can relate to the theory of measurement (see section Measure Theory page 2481). However, the probabilities were studied in the scientific point of view by Pierre de Fermat and Blaise Pascal in the mid 117th century (holocene calendar).

Remark

If you have a teacher or trainer who dare to teach statistics and probabilities only with examples based on gambling (cards, dice, match, toss, etc.) dispose it to whom it may concern because it would mean that he has no experience in the field and he will teach you anything and no matter how (examples could normally be based on industry, pharmaceutics, economy or R&D, in short: areas daily used in companies but especially not on gambling...!).

It is common to distinguish three different main types of probabilities in practice:

D1. "Frequentist probability", also known as "frequentism", is an interpretation of probability that defines an event's probability as the limit of its relative frequency in many trials. In other words, it considers probabilities based on how often an event occurs in repeated experiments or observations.

D2. "Bayesian probability" is interpreted as reasonable expectation or quantification of personal belief rather than just frequency or propensity. A Bayesian probabilist starts by specifying a prior probability for a hypothesis based on available information. As new relevant data (evidence) becomes available, the prior probability is updated to a posterior probability using Bayes theorem (see page 485).

D3. "Fuzzy probability" is an extension of traditional probability theory that deals with mixed probabilistic and non-probabilistic uncertainty. Fuzzy probabilities reflect both aleatory (random) uncertainty and epistemic (knowledge-based) uncertainty separately, providing extended information and decision aids.

5.6.1 Event Universe

quote
5.6:452.#39

> *In physics anything that can happen (meaning has a non-zero probability of occurring) eventually will happen!*

Definitions (#5.6.102):

D1. The "universe of events", or "universe of observables", U is the set of all possible outcomes (results), named "elementary events" that occur during a random determined test. The universe can be finite (countable) if the elementary events are finite or continuous (uncountable) if they are infinite.

D2. Any "event" A is a set of elementary events and is part of the universe of possible U. It is possible that an event is composed of only a single elementary event.

✍**Examples:**

E1. Consider the universe of all possible blood groups, then event A "the individual is Rh positive" is represented by:

$$A=\{A+,B+,AB+,O+\}\subset U \tag{5.6.1}$$

while the event B "the individual is a universal donor" is represented by:

$$B=\{O-\}\subset U \tag{5.6.2}$$

which is therefore an elementary event.

E2. In $(\mathbb{N},+)$ every element is regular and $(\mathbb{N},\times)$ any non-zero element is regular.

D3. Let U be a universe and A an event, we say that the event A "occurs" (or "is realized") if during the run of the trial the issue i $(i\in U)$ occurs and that $i\in A$. Otherwise, we say that A "was not realized".

D4. The empty subset $\varnothing$ of U is named "impossible event". Indeed, if during a trial where the event i occurs, we always have $i\in\varnothing$ and the event $\varnothing$ then never occurred.

If U is finite, or countably infinite, any subset of U is an event, that is no longer true if U is uncountable (we will see in the chapter Statistics why).

D5. The set U is also named "certain event". Indeed, if at the end of the trial the event i occurs, we have always $i\in U$ (since U is the universe of events). The event U then always occurred!

D6. Let A and B be two subsets of U. We know that the events $A \cup B$ and $A \cap B$ are both subsets of U then, events that are respectively "joint events" and "disjoint events".

D7. If two events A and B are such that:

$$A \cap B = \varnothing \tag{5.6.3}$$

the two events may not be feasible during the same trial, then we say that they are "mutually exclusive events".

D8. If two events A and B are such that:

$$A \cap B \neq \varnothing \tag{5.6.4}$$

the two events may be feasible during the same trial (the possibility to see a black cat when we pass under a ladder, for example...), we say conversely that they are "independent events".

D9. "Randomness" (i.e. "random"), at the opposite of "probabilistic" (i.e. "probability"), is the lack of pattern or predictability in events. A random sequence of events, symbols or steps has no order and does not follow an intelligible pattern or combination. Individual random events are by definition unpredictable, but in many cases the frequency of different outcomes over a large number of events (or "trials") is predictable.

Remark

If we randomly (i.e. uniformly) choose a real number in the interval $[0,1]$ then for every number there is a zero probability that we will pick this number. This does not mean that we did not pick any number at all!

Similarly with the rationals, while infinite, and dense and all that, they are very very sparse in the aspect of measure and probability. It is perfectly possible that if we throw countably many darts at the real line we will hit exactly all the rationals and every rational exactly once. This scenario is highly unlikely, because the rational numbers is a measure zero set.

Probability deals with *what are the odds of that happening*? a priori, not a posteriori!! So we are interested in measuring a certain structure a set has, in modern aspects of probability and measure, the rationals have size zero and this means zero probability. More formally, as we will see in the section Statistics page 647, the probabilities are obtained by integrating a probability density function $f(x)$ over an interval. The function is non negative and it has the property:

$$\int\limits_{-\infty}^{+\infty} f(x)\mathrm{d}x = 1 \tag{5.6.5}$$

The probability of selecting a real in an interval $[a,b] \subset \mathbb{R}$ is then given by:

$$P(X \in [a,b]) = \int\limits_{a}^{b} f(x)\mathrm{d}x = 1 \tag{5.6.6}$$

The reader can see now that, given a real number $x_0 \in \mathbb{R}$, we have:

$$P(X = x_0) = P(X \in [x_0, x_0]) = \int_{x_0}^{x_0} f(x)\mathrm{d}x = 0 \qquad (5.6.7)$$

quote

>
> P. S. de Laplace

5.6.1.1 Infinite monkey theorem (Borel's law)

The "infinite monkey theorem ", also named sometimes "Borel's law", states that a monkey hitting keys at random on a typewriter keyboard for an infinite amount of time will almost surely type a given text, such as the complete works of William Shakespeare. In fact the monkey would almost surely type every possible finite text an infinite number of times. However, the probability of a universe full of monkeys typing a complete work such as Shakespeare's Hamlet is so tiny that the chance of it occurring during a period of time hundreds of thousands of orders of magnitude longer than the age of the universe is extremely low (but technically not zero).

In this context, "almost surely" is a mathematical term with a precise meaning, and the "monkey" is not an actual monkey, but a metaphor for an abstract device that produces an endless random sequence of letters and symbols.

Theorem 5.36. If we have an infinite number of monkeys each hitting keys at random on typewriter keyboards then, with probability 1, one of them will type the complete works of William Shakespeare (something like a randomness machine, which is typing keys randomly at a typewriter, would eventually write any book that's ever existed, given enough time).

Proof 5.36.1. Let A_n be the event that the nth monkey types the complete works of Shakespeare. Then if there are m characters on the keyboard and N characters in the complete works of Shakespeare, then the probability to get the complete works of Shakespeare should be (see further below page 523):

$$P(A_n)=\frac{1}{m^N} \tag{5.6.8}$$

for each n. Furthermore the A_n are mutually independent (disjoint event). Hence:

$$\sum_{i=1}^{+\infty}P(A_n)=\sum_{n=1}^{+\infty}m^{-N}=+\infty \tag{5.6.9}$$

Infinitely many of the events A_n occur i.e. infinitely many monkeys will type the complete works of Shakespeare.

■ Q.E.D.

Therefore if we accept infinity in an argument, then we can end up also accepting that "given infinity, anything can happen" (the next example about complex structures will also lead us to the same conclusion!).

Remark

This result is a special case of a more general one named "second Borel–Cantelli lemma". This lemma states that if events E_n are independent and the sum of the probabilities of the E_n diverges to infinity, then the probability that infinitely many of them occur is 1. Ie, if $\sum_{n=1}^{+\infty} P\left(E_n\right) = +\infty$ and the events $\left(E_n\right)_{n=1}^{+\infty}$ are independent, then $P\left(\limsup_{n\to+\infty} E_n\right) = 1$. Formerly:

$$\because \sum_{n=1}^{+\infty} \mathbb{P}\left(E_n\right) = +\infty \wedge \left(\perp\!\!\!\perp E_n\right)_{n=1}^{+\infty} \Rightarrow \mathbb{P}\left(\limsup_{n\to+\infty} E_n\right) = 1 \tag{5.6.10}$$

See the proof just below for more.

quote 5.6:456.#41

> *The true logic of this world is in the calculus of probabilities.*
>
> James Clerk Maxwell

5.6.1.1.1 Second Borel-Cantelli lemma

Theorem 5.37. Let the events E_n be independent and let the sum of the probabilities of the E_n diverges to infinity.

Then the probability that infinitely many of them occur is 1.

That is, if:

$$\sum_{n=1}^{+\infty} P\left(E_n\right) = +\infty \tag{5.6.11}$$

and the events $\langle E_n\rangle_{n=1}^{+\infty}$ are independent, then:

$$P\left(\limsup_{n\to\infty} E_n\right) = 1 \tag{5.6.12}$$

This means that under the right conditions, certain events will almost surely happen infinitely often. This lemma is particularly useful in ergodic theory, number theory, and stochastic processes, where it helps determine whether certain behaviors persist indefinitely.

Proof 5.37.1. Let:

$$\sum_{n=1}^{+\infty} P\left(E_n\right) = +\infty \tag{5.6.13}$$

Let $\langle E_n\rangle_{n=1}^{+\infty}$ be independent. It is sufficient to show the event that the E_n s did not occur for infinitely many values of n has probability 0. This is just to say that it is sufficient to show that:

$$1 - P\left(\limsup_{n\to+\infty} E_n\right) = 0 \tag{5.6.14}$$

Noting that[20]:

$$\begin{aligned}1-P\left(\limsup_{n\to+\infty} E_n\right)&=1-P\left(\{E_n\text{ i.o. }\}\right)=P\left(\{E_n\text{ i.o. }\}^c\right)\\&=P\left(\left(\bigcap_{N=1}^{+\infty}\bigcup_{n=N}^{+\infty}E_n\right)^c\right)=P\left(\bigcup_{N=1}^{+\infty}\bigcap_{n=N}^{+\infty}E_n^c\right)\\&=P\left(\liminf_{n\to+\infty}E_n^c\right)=\lim_{N\to+\infty}P\left(\bigcap_{n=N}^{+\infty}E_n^c\right)\end{aligned}\tag{5.6.15}$$

It is enough to show:

$$P\left(\bigcap_{n=N}^{+\infty}E_n^c\right)=0\tag{5.6.16}$$

Since the $\langle E_n\rangle_{n=1}^{+\infty}$ are independent:

$$P\left(\bigcap_{n=N}^{+\infty}E_n^c\right)=\prod_{n=N}^{+\infty}P\left(E_n^c\right)=\prod_{n=N}^{+\infty}\left(1-P\left(E_n\right)\right)\tag{5.6.17}$$

Let us now introduce the "exponential function inequality", i.e., by the definition of the exponential function (see section Functional Analysis page 2289):

$$e^x=\lim_{n\to+\infty}\left(1+\frac{x}{n}\right)^n\tag{5.6.18}$$

We need now and intermediate result that states that given $x\in\mathbb{R}$ a real number such that $x>-1$ and $n\in\mathbb{Z}_{\geq 0}$ a positive integer, then we get the "Bernoulli's inequality":

$$(1+x)^n\geq 1+nx\tag{5.6.19}$$

- Base Case: For $n=1$, $1+x=1+x$ so the inequality holds.
- Induction Assumption: Assume that for some integer $k\geq 1$, $(1+x)^k\geq 1+kx$.
- Inductive Step: We must show that $(1+x)^{k+1}\geq 1+(k+1)x$

So let's do the proof of the inductive step that confirms Bernoulli's inequality:

$$\begin{aligned}(1+x)^{k+1}&=(1+x)(1+x)^k\\&\geq(1+x)(1+kx)\\&=1+(k+1)x+kx^2\\&\geq 1+(k+1)x,\end{aligned}\tag{5.6.20}$$

since $kx^2\geq 0$. This completes the induction step!

---

[20] In mathematical proofs, the abbreviation "i.o." stands for "infinitely often".

Hence for $x > -1$, we can write using Bernoulli's inequality:

$$\begin{aligned} e^x &= \lim_{n\to+\infty}\left(1+\frac{x}{n}\right)^n \\ &\geq \lim_{n\to+\infty}(1+x) \\ &= 1+x \end{aligned} \tag{5.6.21}$$

Or (we just replace x by $-x$):

$$e^{-x} \geq 1-x \tag{5.6.22}$$

Therefore (the condition $P(E_n) > -1$ is satisfied here to apply Bernoulli's inequality!):

$$\begin{aligned} P\left(\bigcap_{n=N}^{+\infty} E_n^c\right) &= \prod_{n=N}^{+\infty}\left(1-P\left(E_n\right)\right) \\ &\leq \prod_{n=N}^{+\infty}\exp\left(-P\left(E_n\right)\right) \\ &= \exp\left(-\sum_{n=N}^{+\infty}P\left(E_n\right)\right) \\ &= 0 \end{aligned} \tag{5.6.23}$$

This completes the proof.

■ Q.E.D.

5.6.1.2 Do probabilities refute complex structures?

> *The most important questions in life are indeed, for the most part, really only problems of probability.*
>
> P. S. de Laplace

quote 5.6:459.#42

Both traditional creationists and intelligent design writers have invoked probability arguments in criticisms of biological evolution. They argue that some features of biology (for an introduction to biology see [393] and for an excellent introduction to origin of life - abiogenesis - see [453]) are so fantastically improbable that they could never have been produced by a purely natural, "random" process, even assuming the billions of years of history asserted by geologists and astronomers. They often equate the hypothesis of evolution to the absurd suggestion that monkeys randomly typing at a typewriter could compose a selection from the works of Shakespeare, or that an explosion in an aerospace equipment yard could produce a working 747 airliner (we won't give the name of the people that wrote that because the quality of their book and their religious agenda don't deserve to be quoted here!). More recent studies of this type, in an attempt to promote an "intelligent design" world-view, argue that functional biology operates on an exceedingly small subset of the space of all possible DNA sequences, and that any changes to the "computer program" of biology are, like changes to human computer programs, almost certain to make the organism non-functional (again we won't give the name of people who claim that for the same reasons as before!).

Definition (#5.6.103): "Biological evolution" is the cumulative change in the heritable characteristics properties of groups of structures over the course of generations through seconds to millions years depending on the type of structures. It embraces everything from slight changes in the proportions of different forms of a coding structure due to natural environment constraints, random sequential genetic drift and genetic variations within a population to the alterations that led from the earliest self-replicating molecules structures to organisms, dinosaurs, bees, oaks, humans, etc. (notice the subtlety of the definition thanks to the underlined word that avoid to have the "fire" to be an entity having a biological evolution...).

While not generally appreciated by the public at large, it is a well-known fact in the world of scientific research that arguments based on probability and statistics are fraught with potential fallacies and errors, and even "expert" researchers can fool themselves with invalid reasoning. For these reasons, rigorous courses in probability and statistics are now required of students in virtually all fields of science (keep in mind that engineering is not science, this is why actually the huge majority of engineers have a very low understanding of probabilities and statistics), and in numerous other disciplines as well. Attorneys need to be at least moderately well-versed in probability and statistics arguments and how they can go awry in the courtroom arguments. In the finance world, statistical over-fitting and other errors of probability and statistics are now thought to be a leading reason behind the fact that many strategies and investment funds which look great on paper often fail miserably in real-world usage.

To illustrate the difficulties with probability arguments, mathematics teachers often ask their class (let's say it has 23 students) if they think it is likely that two or more persons in the class have exactly the same birthday. Most students say that it is highly unlikely, thinking that the chances that two people have the same particular birthday is $1/365$, and so 23 times this amount is only $23/365$. But this argument is fallacious, indeed, if one numbers the 23 people from 1 to 23, the event that all 23 people have different birthdays is the same as the event that person 2 does not have the same birthday as person 1, and that person 3 does not have the same birthday as either person 1 or person 2, and so on, and finally that person 23 does not have the same birthday as any of persons 1 through 22.

Let these events respectively be named "Event 2", "Event 3", and so on. One may also add an "Event 1", corresponding to the event of person 1 having a birthday, which occurs with probability 1. This conjunction of events may be computed using conditional probability: the probability of Event 2 is $364/365$, as person 2 may have any birthday other than the birthday of person 1. Similarly, the probability of Event 3 given that Event 2 occurred is $363/365$, as person 3 may have any of the birthdays not already taken by persons 1 and 2. This continues until finally the probability of Event 23 given that all preceding events occurred is $343/365$. Finally, the principle of conditional probability implies that the probability $P(A')$ that no two people in the room have the same birthday is equal to the product of these individual probabilities:

$$P(A')=\frac{365}{365}\cdot\frac{364}{365}\cdot\frac{363}{365}\cdot\frac{362}{365}\cdot\ldots\cdot\frac{343}{365}=\left(\frac{1}{365}\right)^{23}\cdot(365\cdot 364\cdot 363\cdot\ldots\cdot 343)\cong 0.492703 \tag{5.6.24}$$

Therefore, the probability that at least two people in the class have the same birthday is given by (as both events are mutually exclusive):

$$P(A)=1-P(A')\cong 1-0.492703\cong 0.507297 \tag{5.6.25}$$

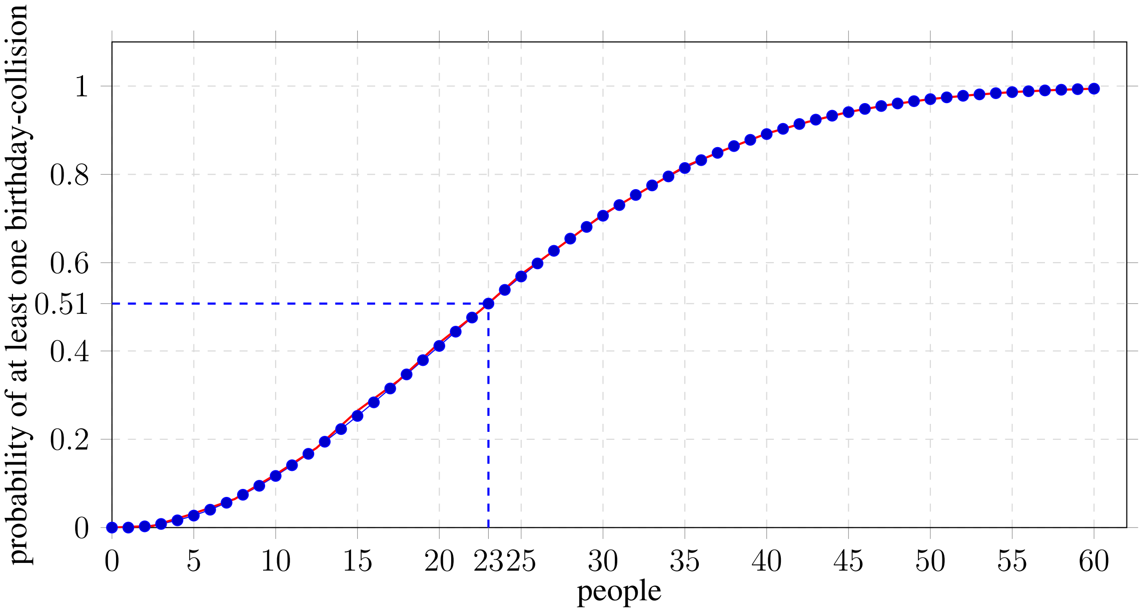

Figure 5.77: **Birthday paradox probability distribution**

One creationist-intelligent design argument (high-school level argument...) goes like this: the human alpha-globin molecule (abbreviated HBA1), a component of haemoglobin that performs a key oxygen transfer function, is a protein chain based on a sequence of 141 amino acids[21] (average mass of 10^{-25} [kg]), keeping in mind that the smallest known protein at the day we write these lines is made of only 10 amino acids (see [260]). There are 20 common different amino acids in living systems[22]:

Figure 5.80: **Concomitant formation of protocells and prebiotic compounds in the Miller-Urey experiment**

With the sequencing of the alpha-globin that is:

```
Val-Leu-Ser-Pro-Ala-Asp-Lys-Thr-Asn-Val-Lys-Ala-Ala-Trp-Gly-Lys-Val-Gly
-Ala-His-Ala-Gly-Glu-Tyr-Gly-Ala-Glu-Ala-Leu-Glu-Arg-Met-Phe-Ser-Phe-Pro
-Thr-Thr-Lys-Thr-Tyr-Phe-Pro-His-Phe-Leu-Ser-His-Gly-Ser-Ala-GIn-Val-Lys
-Gly-His-Gly-Lys-Lys-Lys-Val-Ala-Asp-Ala-Leu-Thr-Ala-Val-His-Val-Hal-Hal
-Hsp-Met-Pro-Asn-Ala-Leu-Ser-Ala-Leu-Ser-Asp-Leu-His-Ala-Heu-Arg-Val-Asp
-Pro-Val-Asn-Phe-Lys-Leu-Leu-Ser-His-Cys-Leu-Leu-Leu-Ala-His-Leu-Pro-Ala
-Glu-Phe-Thr-Pro-Ala-Val-His-Ala-Ser-Leu-Asp-Lys-Phe-Leu-Ala-Ser-Val-Ser
-Thr-Val-Leu-Thr-Ser-Lys-Tyr-Arg
```

Or for an abbreviated version of the four polypeptide chains:

- Chain A:
  ```
  VLSPADKTNV KAAUGKVGAH AGEYGAEALE RMFLSFPTTK TYFPHFDLSH GSAOVKGHGK
  KVADALTHAV AHVDDMPMAL SALSDLHAHK LRVDPVNFKL. LSHCLLVTLA AHLPAEFTPA
  VHASLDKFLA SVSTVLTSKY R
  ```
- Chain B:
  ```
  VHLTPEEKSA VTALUGKVNV DEVGGEALGR LLVVYPUTOR FFESFGDLST pDAVHGWRV
  KAHGKKWLGA FSDGLAHLDN LKGTFATLSE LHCDKLHWDP ENFRLLGNVL VCVLAHHFGK
  EFTPPVOAAY OKVVAGVANA LAHKYH
  ```
- Chain C:
  ```
  WLSPADKTNV KAAUGKVGAH AGEYGAEALE RMFLSFPTTK TYFPHFDLSH GSAOVKGHGK
  KVADALTNAV AHVDDHPNAL SALSDLHAHK LRVDPVNFKL LSHCLLVTLA AHLPAEFTPA
  VHASLDKFLA SVSTVLTSKY R
  ```
- Chain D:
  ```
  WHLTPEEKSA VTALUGKVNV DEVGEEALGR LLWYPUTOR FFESFGDLST PDAVMGNPKV
  KAHGKKVLGA FSDGLAHLDN LKGTFATLSE LHCDKLHVDP ENFRLLGNVL VCVLAHHFGK
  EFTPPVQ
  ```

So the number of potential chains of length 141 is[23] (see further below page 523 for the proof):

$$\bar{A}_m^n = n^m = 20^{141} \cong 10^{183} \tag{5.6.26}$$

The creationists and also many theists argue then that this figure is so enormous that even after billions of years of random molecular trials, no human alpha-globin protein molecule would ever appear "at random," and thus the hypothesis that human alpha-globin arose by an evolutionary process is decisively refuted.

---

[23] This calculation is anyway quite wrong as symmetrical permutations (mirror results) are counted - but it won't however change the order of magnitude of the result - and experimental evidence have shown that there are forbidden/unstable sequences of amino acids!

Definition (#5.6.104): "Life" (i.e. "autocatalytic set" in chemistry) is a chemical system capable of undergoing biological evolution (see definition above at page 459) through self-replication[24] using the resources of its environment (notice again the subtlety of this definition referring to that of "biological evolution" to avoid to have the "fire" classified as a living entity...!).

Remark

In 12023 (holocene calendar), Ryo Mizuuchi and Norikazu Ichihashi (see [396]), identified a 20-nucleotide RNA variant that self-reproduces! As a nucleotide is made of 5 carbon atoms, 8 hydrogen atoms, 1 nitrogen atom, 1 phosphorus atom, 4 oxygen atoms therefore a single nucleotide contains 19 atoms (the number of possible combinations based on the highest valence case of each atom is therefore $4^5 1^8 5^1 5^1 2^4 = 409,600 \cong 10^{5.612}$ hence much much smaller than the 10^{183} argument used by creationists...). That means the smallest known RNA that can self-reproduce has only $19 \cdot 20 = 380$ atoms! Furthermore, another scientific team (see [354]) was able to develop spontaneous emergence of self-replicating molecules containing nucleobases and amino acids (what some people qualify of "creating life from non-life" or "non-life producing life") and another team was able to develop synthetic self-replicating cells (see [308])! Another interesting paper is the one relating to an experiment observing a small non-synthetic polymerase of only 45 nucleotides from a pool of random sequences that reproduces itself (see [201]).

One major fallacy in the alpha-globin argument mentioned above, common to many others of this type, is that it ignores the fact that a large class of alpha-globin molecules can perform the essential oxygen transfer function, so that the computation of the probability of a single instance is misleadingly remote. Indeed, most of the 141 amino acids in alpha-globin can be changed without altering the key oxygen transfer function, as can be seen by noting the great variety in alpha-globin molecules across the animal kingdom. When one revises the calculation above, based on only 25 locations essential for the oxygen transport function (which is a generous over-estimate), one obtains 10^{33} fundamentally different chains, an enormous figure but incomparably smaller than 10^{183}. And keep in mind that it's the number if we assume a total independence! The slightest constraint can greatly reduce this value. Keep in mind, for example, the problem of the 100 prisoners whose probability goes from $8 \cdot 10^{-31}$ to about $\sim 31\%$ just by adding a stupid constraint (see Wikipedia for the explanation of this problem and the detailed proof)...

A calculation such as this can be refined further, taking into account other features of alpha-globin and its related biochemistry. Some of these calculations produce probability values even more extreme than the above. But do any of these calculations really matter[25]? The main problem is that all such calculations, whether done accurately or not, suffer from the fatal fallacy of presuming that a structure such as human alpha-globin arose by a single all-at-once random trial event. But generating a molecule "at random" in a single shot is decidedly not the scientific hypothesis in question – this is a creationist theory, not a scientific theory. Instead, available evidence from hundreds of published studies on the topic has shown above any reasonable doubt that alpha-globin arose as the end product of a long sequence of intermediate steps, each of which was biologically useful in an earlier context.

---

[24] Autocatalysis, the ability of systems (molecules, metabolic networks or compartments) to make copies of themselves, is central to all evolutionary scenarios. Systems where autocatalysis is accompanied by information transfer and heredity are said to be self-replicating!

[25] For example a physicist applying the scientific method with the frequentist approach will calculate the odds of the appearance of life with the available experimental evidence! Thus the current data available to us gives us 1 observable universe and 1 life, meaning 100% probability (i.e. the probability of observing life statistically according to the available sample).

In short, the creationist-intelligent design argument claiming that scientists assert an all-at-once "at random" creation of various biomolecules, and then asserting that this is probabilistically impossible, is a classic "straw man" fallacy. Scientists do not believe this, so this line of argumentation is completely invalid. In other words, it does not matter how good or how bad the mathematics used in the analysis is, if the underlying model is a fundamentally invalid description of the phenomenon in question. Any simplistic probability calculation of evolution that does not take into account the step-by-step process by which the structure came to be is almost certainly fallacious and can easily mislead!

Some of the difficulties with creationist probability arguments can be illustrated by considering snowflakes (even if we must keep in mind that *comparison is not reason*!). Bentley and Humphrey's book *Snow Crystals* includes over $2,000$ high-resolution black-and-white photos of real snowflakes, each with intricate yet highly regular patterns that are almost perfectly six-way symmetric (see [350] for more details).

By employing a reasoning based on six-way symmetry, one can calculate the chances that one of these structures can form "at random" as roughly one part in 10^{2500}. This probability figure is even more extreme than some that have appeared in the creationist-intelligent design literature. So is this proof that each individual snowflake has been designed by a supernatural intelligent entity? Obviously not.

One of the fallacy here, once again, is presuming an all-at-once random assembly of molecules. Instead, snowflakes, like biological organisms, are formed as the product of a long series of steps acting under well-known physical laws, and the outcomes of such processes very sensitively depend on the starting conditions and numerous environmental parameters. It is thus folly to presume that one can correctly reckon the chances of a given outcome by means of superficial probability calculations that ignore the processes by which they formed.

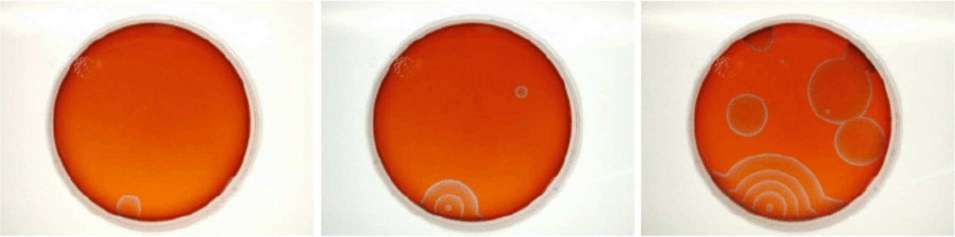
Remark

Notice also the art of cherry picking from theists and creationists. A deity created something "perfect" as DNA (or trees whatsoever!). However he did it with almost 4 or 6 thousands genetic disease (coding errors), with a light source (Sun) that gives cancer, on a planet (Earth) where the majority of water is undrinkable[a], near a star (Sun) that will explode, in a orbit that will make the planet unlivable in a few billion years, in a finite resource ecosystem with deadly rampant diseases, in a universe in majority uninhabitable... Yes logic makes sense!

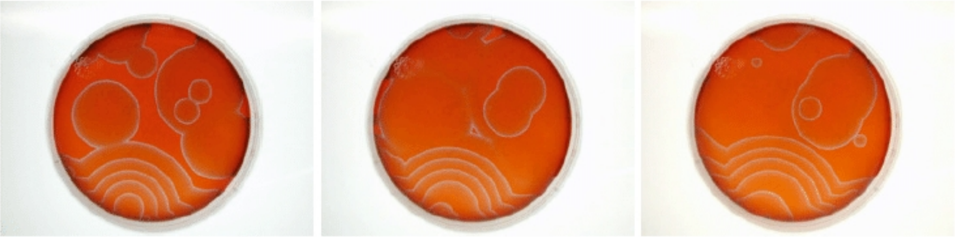
---

[a] Water quantities types varies hugely across time on Earth (for example new research indicates that our planet was an ocean world some 3 billion years ago). But actually in the 21st century water from oceans and marginal seas, saline groundwater and water from saline closed lakes amount to over 97% of the water on Earth (corresponding to approximately $70.9 \pm 3.5\%$ of Earth's area, seas represents approximetely 11.3%). Only 2.5% is made of freshwater (itself made of 1.2% of surface water, 30.1% of ground-water and 88.7% of glaciers and ice caps).

Another famous example of randomness creating structures are the Belousov–Zhabotinsky reaction, that is a class of reactions that serve as a classical example of non-equilibrium thermodynamics, resulting in the establishment of a non-linear chemical oscillator (it is "random" in the way that the final patterns we get are very unlikely to be identical between two same experimental configuration!):



(a) Initial (b) $t = 3sec$ (c) $t = 9sec$



(d) $t = 12sec$ (e) $t = 15sec$ (f) $t = 18sec$

It's time to put some numbers on the formulas of statistical mechanics to bring home just how impressive the things going on inside our cells actually are.

To start, we live (actually...) at temperatures of approximately 300 [K]. If you have studied statistical mechanics you know that the kinetic energy of a molecule is given by (see section Continuum Mechanics page 3897):

$$E_c=\frac{N}{2}mv^2=\frac{3}{2}kNT=\frac{3}{2}\frac{R}{N_A}NT \tag{5.6.27}$$

Therefore:

$$\bar{v}=\sqrt{\frac{3RT}{mN_A}} \tag{5.6.28}$$

Or in terms of molar mass:

$$\bar{v}=\sqrt{\frac{3RT}{M_m}} \tag{5.6.29}$$

Therefore for water with $18.01528\cdot 10^{-3}$ $[\text{kg}\cdot\text{mol}^{-1}]$ this gives at room temperature:

$$\bar{v}=\sqrt{\frac{3\cdot 8.314\cdot 300}{18.01528\cdot 10^{-3}}}\cong 644\;[\text{m}\cdot\text{s}^{-1}] \tag{5.6.30}$$

This is not a too bad result as many sources give 590 $[\text{m}\cdot\text{s}^{-1}]$. We will take that latter value.

The thermal velocity relation works even for something as large as RNA polymerase II ($\sim 830\cdot 10^{-24}$ [kg]).

To make things really easy lets work with a molecular complex of mass even bigger (i.e. more complex). Something as: $1\cdot 10^{-21}$ [kg]. Such a mass would have an average thermal velocity of:

$$\bar{v}=\sqrt{\frac{3RT}{mN_A}}\cong\sqrt{\frac{3\cdot 8.314\cdot 300}{1\cdot 10^{-21}\cdot 6.0221\cdot 10^{23}}}\cong 3.52\;[\text{m}\cdot\text{s}^{-1}] \tag{5.6.31}$$

Let us take a lower bound of 2 $[\text{m}\cdot\text{s}^{-1}]$ according to some non peer-reviewed sources.

Cells are small. The three polymerases transcribed DNA into RNA have masses in the order of $1\cdot 10^{-21}$ [kg] range. So how long should it take them to go through a quite big cell nucleus of 10 microns (10^{-5} [m]) in diameter? If it's going at 2 $[\text{m}\cdot\text{s}^{-1}]$ so it will traverse it statistically in average $250,000$ times in a second[26] or one time every 4 $[\mu\text{s}]$.

We clearly left something out — nothing in the cell moves in a straight line. It is very crowded, so that even though things are moving very quickly their trajectory isn't straight obviously!

We have proved in the section of Continuum Mechanics (page 3925) that the average distance travelled by a molecule (assumed as spherical) between two collisions is given by:

$$\lambda=\frac{1}{n\pi r^2\sqrt{2}} \tag{5.6.32}$$

---

[26] For people interested to see a numerical simulation video of a Brownian motion of proteins inside a bacterial cytoplasm like that of E. Coli, see [379].

And we proved at the same place that the number of collision per second were given by:

$$C=n\pi r^2\sqrt{2}\bar{v}=n\pi r^2\sqrt{2}\sqrt{\frac{3RT}{mN_A}} \tag{5.6.33}$$

To calculate how much water can fit into a cell nucleus, we need to know how big is that latter. A source says that water can be considered a squashed sphere of maximum radius of 1.41 Angstroms (10^{-10} [m]).

So what is the volume of a water molecule? It's:

$$V_{\text{H}_2\text{O}}=\frac{4}{3}\pi r^3=\frac{4}{3}\pi(1.41\cdot 10^{-10})^3\cong 1.174\cdot 10^{-29}\;[\text{m}^3] \tag{5.6.34}$$

So the density of molecules is given by:

$$n=\frac{1}{1.174\cdot 10^{-29}}\cong 8.5\cdot 10^{28}\;[\text{molecules}\cdot\text{m}^{-3}] \tag{5.6.35}$$

Therefore:

$$\lambda=\frac{1}{n\pi r^2\sqrt{2}}=\frac{1}{3.5\cdot 10^{14}\cdot\pi\cdot(1.41\cdot 10^{-10})^2\sqrt{2}}\cong 1.4\cdot 10^{-10}\;[\text{m}] \tag{5.6.36}$$

and (still for water only and in one cube meter!):

$$C=n\pi r^2\sqrt{2}\bar{v}=8.5\cdot 10^{28}\cdot\pi\cdot(1.41\cdot 10^{-10})^2\cdot\sqrt{2}\cdot 644\cong 4.8\cdot 10^{12}\;[\text{collisions}\cdot\text{s}^{-1}] \tag{5.6.37}$$

so it's like to meet another molecule of water every (roughly) 10^{-12} seconds (1 pico-second).

Notice a billion years has:

$$60\cdot 60\cdot 24\cdot 365\cdot 1\cdot 9\cong 3.15\cdot 10^{16}\;[\text{s}] \tag{5.6.38}$$

So we have roughly by billion years a total of collision for one cubic meter equal to:

$$C_{\text{bill. years}}=4.8\cdot 10^{12}\cdot 3.15\cdot 10^{16}\cong 1.5\cdot 10^{29}\;[\text{collisions}\cdot\text{billion years}^{-1}] \tag{5.6.39}$$

And as the amount of water on Earth is estimated roughly at (assuming that all this water was involved equally on the whole planet to the same chemical processes and conditions...):

$$V_{\text{Earth H}_2\text{O}}\cong 1\cdot 10^{18}\;[\text{m}^3] \tag{5.6.40}$$

Therefore on the whole Earth we have:

$$C_{\text{Tot}}\cong 1.5\cdot 10^{29}\cdot 1\cdot 10^{18}\cong 1\cdot 10^{36}\;[\text{collisions}\cdot\text{billion years}^{-1}] \tag{5.6.41}$$

So per billion years we have $1,000$ times more collisions than the number 10^{33} of combinations of different chains of the alpha-globin. Even if we consider a factor 100 of errors in the number of collisions per second (it's not impossible that it is our magnitude of error in our estimations!), we would need only 1 billion years to try all 10^{33} combination just by random collisions.

Keep in mind that this is the result for considering only one Earth planet like (ours). Whatever the result, we should have multiplied it by the lower bound approximation of Earth like planets in our Galaxy (estimated in the year 12020 according to holocene calendar between 1 to 6 billion, i.e. $\sim 10^9$, see [36]) and the number of galaxies in the observable Universe (estimated between 100 billion and 2 trillion, i.e. between 10^{11} and 10^{12}, see [111]). And this is only for the observable Universe... (keeping in mind that the Universe is to our actual knowledge very likely flat and therefore infinite with $\Omega_0 = 1$ or $k = 0$ as seen in the section of Cosmogony page 5897 or at least 250 bigger as detailed in [555]).

At the time we write these lines, early 121st century according to Holocene calendar, it is pretty much sure that thanks to the James Webb Telescope biosignatures (i.e. life) have been found on other planets, it's just that astrophysicists are not yet allowed to say it. In the professional circle of astrophysicists in spectroscopy it is known that there are so many plausible exoplanetary atmospheric biosignatures that have been detected that there's no longer any doubt, but the standard of proof for official acceptance is just incredibly high. The most statistical significant case - at a 3σ level actually - being the planet K2-18b (this planet is a little larger than Earth in a solar system about 124 light years away in the habitable zone of a red dwarf) with the detection of dimethyl sulfide at concentrations that seem to be thousands of higher than on Earth. On Earth this gas is produced almost exclusively by marine microbes.

The results of these calculations demonstrate that the assertions about the "impossible" probabilities of life - made without mathematical proof by Nobel laureate George Wald and by astronomer Fred Hoyle - are entirely unfounded. This illustrates why even Nobel Prize winners, like all scientists, should refrain from making authoritative claims on topics that fall outside their own field of expertise

Let us quote one of the 12019 (holocene calendar) Nobel Prize in Physics:

> *The emergence of life is ultimately a chemical process. If the conditions are right, life will emerge. I see no need for an initial push from a creator god.*
>
> Didier Queloz

quote 5.6:469.#43

Anyway the reader must remember that the probability of something happening as a determinate to it happening is not relevant if it has actually happened!

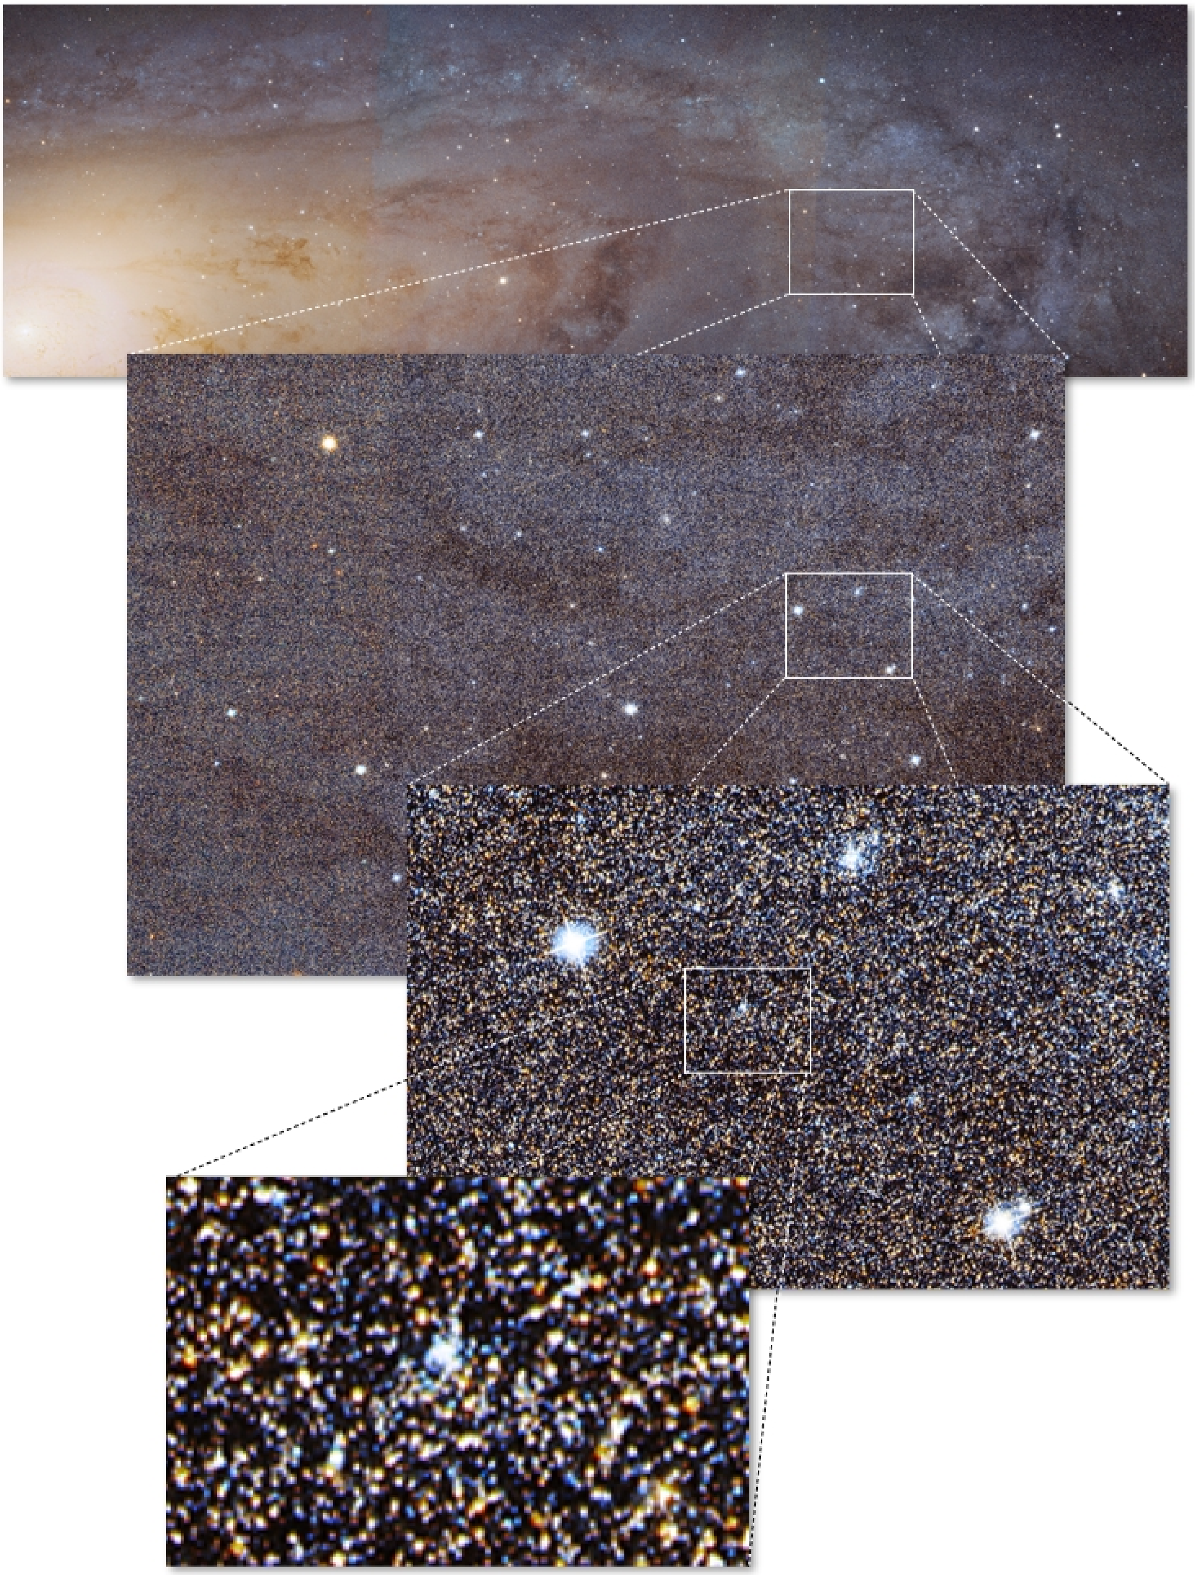


Figure 5.81: Hubble space telescope sharpest and largest M31 (Andromeda galaxy) image ever with 1.5 billion pixels with approximately 100 million stars across over 40,000 light-years released the in 12015, 5 January (credit: NASA, ESA, J. Dalcanton (University of Washington, USA), B. F. Williams (University of Washington, USA), L. C. Johnson (University of Washington, USA), the PHAT team, and R. Gendler)

Remark

So far we see that the main factor here for the number of collisions is not the radius of the molecules involved, nor their speed or their mass but their quantity (i.e. density). Obviously the time is important but there is now too much incertitude about the range of that latter.

But let us be more realistic! We should take into account that:

1. Water is not amino acids (the biggest amino acid has a weight of 204.2 $[\text{g}\cdot\text{mole}^{-1}]$) and there are elastic collisions between water molecules and such organic molecules.
2. The water molecules density is not equal to that of amino acids density per litre of water. Sadly this is a value it seems we don't have access to and is highly speculative[27].

Let us consider the relation for an elastic collision in one dimension (see section Classical Mechanics page 3369):

$$v_{2f}=\frac{2m_1}{m_2+m_1}v_{1i}+\frac{m_2-m_1}{m_2+m_1}v_{2i} \tag{5.6.42}$$

And let us consider the worst case where $v_{2i}=0$. Then:

$$v_{2f}=\frac{2m_1}{m_2+m_1}v_{1i}=\frac{2\cdot 18}{18+204.2}\cdot 644\cong 104\;[\text{m}\cdot\text{s}^{-1}] \tag{5.6.43}$$

So the speed of amino acids would only decrease our number of collisions by maximum a factor 10. Not enough to make "life" something rare on the scale of a billion years (to make it rare we should have at least a decrease in an order of $10,000$).

Let us do now some reverse engineering. To make emerging life rare on a billion years scale, as already mentioned and thanks to previous calculations, we should have a least a decrease of $10,000$. Thanks the to the elastic collision, we can take down this value to $1,000$.

So we should found somewhere, something in our calculations, to make the collisions $1,000$ times more rare. The idea would take this into the parameter n (molecules density) in the above relations. If we assume that the ratio of amino acid to water molecules is at 1 for $1,000$ then it starts to make things difficult on the scale of a billion years! That means in 1 mole of water (i.e. 18 [g] or 18 [ml]), we would have 0.018 [g] of amino acid.

So as other extra-solar planets were something unlikely a century ago, it is very likely that the future provides evidence that life is something very common on planets that have water or atmospheres with the right components and temperature on a time range of the billion years.

Remark

Some scientifically illiterate people may argue that Roger Penrose calculated that the probability for our Universe (on the assumption that the latter is in a Black Hole...) to be in the low entropy he is now is about 10^{123} to 1. Hence it is impossible for our Universe to not have been created by a deity (passing under silence the question of who created that complex deity...). But it is irrelevant! Even if what Penrose said is 100% accurate or off by a factor of a googol, it's irrelevant!! Indeed, if we run a computer program that emulates a coin flipped one billion times and that we write the sequence of heads and tails to a file, then we just produced a sequence more than a trillion trillion trillion times rarer!! In fact, we could run that same computer program until the end of human existence and it would likely never produce that same string of outcomes. And yet it occurred nonetheless...

---

[27] It is related to the problem of proportion compounds of the Miller-Urey experiment.

If one feels inclined, one can try to estimate the probability of one's own existence. A naïve calculation would multiply the chance that a specific sperm met a specific egg by the chance that one's parents happened to meet, that one's grandparents crossed paths, and so on through the entire ancestral line. Unsurprisingly, the resulting probability is vanishingly small. Yet this is precisely the point: events of extremely low probability occur constantly in our universe. And once such an event has happened, its probability becomes 100%.

Remark

The reader will also note the art of cherry picking among believers and creationists. A deity would have created something "perfect" like DNA (or trees, whatever!). However it would have done it with nearly 4 to 6 thousand genetic diseases (coding errors), with a source of light (Sun) which gives cancer, on a planet (Earth) where the majority of water is undrinkable near a star (Sun) which will explode and which is in an orbit which will make it unlivable in a few billion years, with an ecosystem of limited resources with endemic deadly diseases, in a universe mostly uninhabitable... Yes that makes sense hmmm...

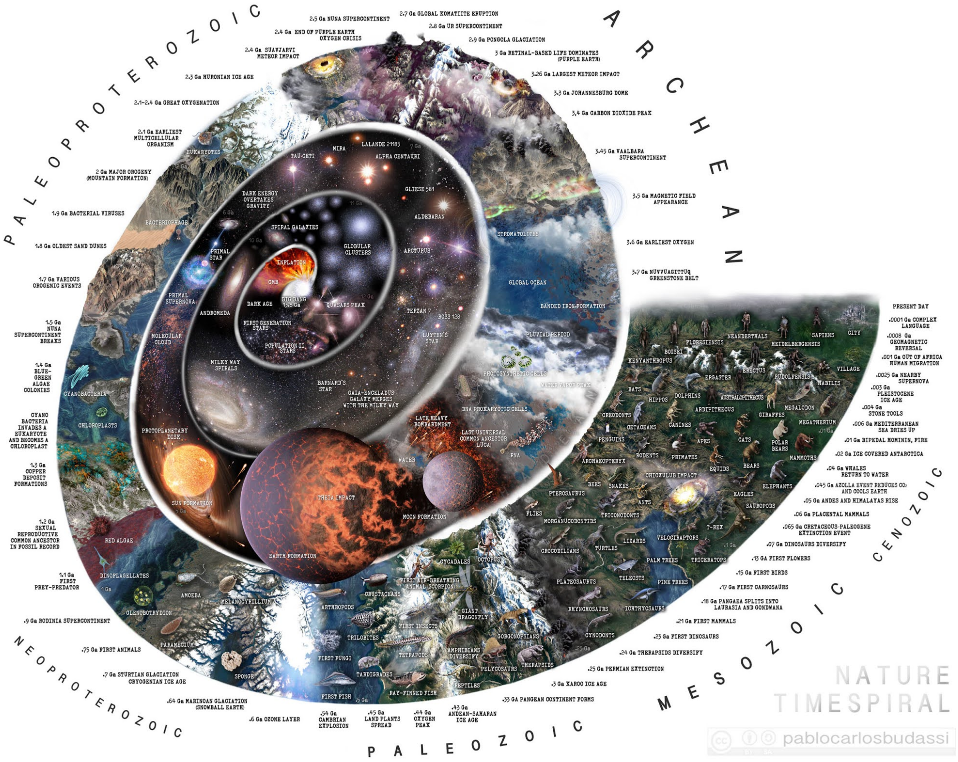

Figure 5.82: Nature Timespiral (author: Pablo Carlos Budassi)

By the way in 12025 (holocene calendar) scientists have found abundant ammonia and nitrogen-rich soluble organic matter in samples from asteroid (101955) Bennu (see [205]). This includes amino acids (including 14 of the 20 used in terrestrial biology), amines, formaldehyde, carboxylic acids, polycyclic aromatic hydrocarbons and N-heterocycles (including all five nucleobases found in DNA and RNA).

Remark

Another fallacy of bigots is that the probability of cellular life's arising from non-living matter (abiogenesis) as calculated by Fred Hoyle is about one-in-$10^{40,000}$. But there is no sources from Fred Hoyle with the detailed mathematical derivation that lead to this value. Another lie from religious people...! There is also the Junkyard tornado analogy used by bigots but as we have already proved it: all analogies are wrong equivalences!

> ❞ *I have your letter and the best thing I can do is refer to my published works, both scientific and popular. The creationist movement is lead by a dishonest bunch of operators and misquotation is the hall mark of their work. Responding to them is time wasting and a letter would not be adequate to put your questions to rest. There are some things best ignored and the stupidity of these so called religious fanatics continues to astonish me.* ❞
>
> Richard Leakey

quote 5.6:473.#44

Description	**Probability** (or estimated)
Probability of dying one day or another	100%
Probability of >7 Richter scale earthquake somewhere on Earth during your lifetime	100%
Probability of erupting volcano somewhere on Earth during your lifetime	100%
Six Sigma management probability to produce a defect-free product	99.99966%
Banking regulatory sector (Basel Committee 12022) Value at Risk (VaR) threshold	99%
Banking regulatory sector (Basel Committee 12022) Expected Shortfall (ES) threshold	97.5%
Prior statistical test typical power (type II error)	80%
Probability of flipping a coin and it landing on heads	50%
Probability of experiencing a pandemic in one's lifetime	$\sim$ 38%
The 100 prisoners problem optimal solution	$\sim$ 31.18%
Probability of massive star forming a black hole (unovae)	$\lesssim$ 10-30%
Probability of identical birthday in a group of 23 people	50%
Probability of dying from any given cancer during lifetime	$\sim$ 18%
Probability of rolling a six on a six-sided dice	$16.\bar{6}$%
Probability of miscarriage	$\sim$ 15.3%
Typical p-value threshold in social and medical science (type I error)	5%
Probability of a baby to born with a birth defect	$\sim$ 2.63%
Probability of winning roulette game in a casino	$\sim$ 2.6%
Probability of drawing an Ace of Spades from a deck of cards	$\sim$ 1.92%
Probability of having a stroke for people aged between 35-40	1.4-2.3%
Typical p-value threshold in engineering science (type I error)	1%
Probability of dying from a heart attack during lifetime	$\sim$ 0.99%
Probability of a newborn to have a genetic anomaly	$\sim$ 0.2%
Probability 10 km size asteroid colliding Earth during your lifetime	0.0000830%
Probability that you will die tomorrow as "average" human	0.000001%
Typical p-value threshold in particle physics (type I error)	$\sim$ 0.000001%
Probability of getting a royal flush in poker	0.00000154%
Probability of winning the Powerball jackpot	0.00000021%
Fatality probability for an average person using an average commercial flight	$\sim 3\cdot 10^{-8}$
Probability of two identical fingerprints according to Jackson Gold and Maria Cuellar	$\sim 7\cdot 10^{-8}$
Fatality probability for an average person crossing an average road	$\sim 4\cdot 10^{-9}$
Fatality probability for an average person using an average lift	$\sim 1\cdot 10^{-10}$
Probability of tunnel effect in polonium decay process	10^{-15}
Probability of alpha-globin formed completely by chance based on amino-acides on Earth like planets in the observable Universe	$\sim 10^{-4}$-10^{-10}
Probability of alpha-globin formed completely by chance based on amino-acides only on Earth	$\sim 10^{-25}$-10^{-31}
Probability of two identical fingerprints according to Francis Galton	2^{-36}
Probability of the actual entropy of our Universe according to Roger Penrose calculation	$\sim 10^{-123}$%
Probability of rolling fifty six-sided dices and get a given result	$\sim 10^{-300}$%
Probability a monkey rewrites *Hamlet* by chance	$\sim 10^{-182,856}$
Probability of being born	$\sim 10^{-2,685,000}$
Probability of human to cross a wall by tunnelling effect	$\sim 10^{-4.10^{30}}$
Probability of our universe to exist as it is	$\sim 10^{-272,000}$ -$10^{-10^{500}}$

Table 5.25: **Some famous probabilities (and estimations) values as known in the early 121st century**

> *Nature wants 5 of your 7 children dead. It wants you dead by 50. Everything better than that is brought to you by science and technology.*
>
> David Frum

quote 5.6:474.#45

5.6.2 Kolmogorov's Axioms

In Chapter 2 of *A First Course in Probability*, Sheldon Ross cautions us against "defining" probability as the limiting proportion of events over repeated samples/ trials/experiments: «*...it does not at all seem to be a priori evident that this [limiting frequency] need be the case. Also,..., how do we know that if the experiment is repeated..., we shall again obtain the same limiting proportion...? ...would it not be more reasonable to assume a set of simpler... axioms... and then attempt to prove [mathematically] that such a constant limiting frequency does in some sense exist... [using] the law of large numbers... This latter approach is the modern axiomatic approach to probability theory...*»

On the surface, this seems entirely appropriate; however, under this formalism, it appears we must treat probability, P, as an ethereal and ephemeral characteristic of an event A pertaining to any particular trial - i.e., an unfalsifiable causative propensity. Then, the strong law of large numbers (SLLN) is a theorem to be rigorously proven[28] mathematically stating that: the limiting proportion of events over repeated trials converges to this very same propensity. Ie:

$$\lim_{n\to+\infty}\sum_{i=1}^{n}\frac{X_i}{n}=\bar{X} \qquad (5.6.44)$$

From this perspective, the existence of a limiting proportion is a consequence resting on unfalsifiable axioms!

Remark

The weak law of large numbers states that for a specified large n, the average $\bar{X}_n$ is likely to be near μ (see page 920 for the detailed proof). Thus, it leaves open the possibility that $\left|\bar{X}_n-\mu\right|>\varepsilon$ happens an infinite number of times, although at infrequent intervals.

The strong law of large numbers shows that this almost surely will not occur. Note that it does not imply that with probability 1, we have that for any $\varepsilon>0$ the inequality $\left|\bar{X}_n-\mu\right|<\varepsilon$ holds for all large enough n, since the convergence is not necessarily uniform on the set where it holds.

The probability of an event is somehow responding to the notion of frequency of a random phenomena, in other words, at each event we will attach a real number in the interval $[0,1]$, which measure the probability (chance) of realization. The properties of frequencies we can highlight during various trials allow us to determine the properties of probabilities.

Let U be a universe.

Definition (#5.6.105): We say that we define a "probability" on the events of U if to any event A of U we associate a number or measure $P(A)$, named "a priori probability of event A" or "marginal probability of A" and also shortly named "credence of A" (strength of conviction, expressed as a percentage, of a rational agent, about a hypothesis as defined in [284], it is therefore not a belief as the latter is associated to irrational agents that are unable to quantify their hypothesis).

---

[28] The detailed proof of the strong law of large numbers is actually, due to its difficulty, out of the scope of this textbook. That's also the reason why the huge majority of engineers and postgraduate physicists, astrophysicts, cosmologists, biologists, chemists, etc. don't study it during their curriculum.

Here are the "Kolmogorov's axioms":

A1. For any event A:

$$\boxed{1 \geq P(A) \geq 0} \tag{5.6.45}$$

Thus, the probability of any event is a real number between 0 and 1 inclusive (this is common human sense...).

A2. The probability of the certain event or of the set (sum) of possible events is equal to 1:

$$\boxed{P(U) = 1} \tag{5.6.46}$$

A3. If $A \cap B = \varnothing$, i.e. the two events are incompatible (disjoint), then:

$$\boxed{P(A \cup B) = P(A) + P(B)} \tag{5.6.47}$$

the probability of the merge ("or") of two mutually incompatibles events (or mutually exclusive) is therefore equal to the sum of their probabilities (law of addition). We then speak of "disjoint probability".

We understand better that the third axiom requires $A \cap B = \varnothing$ otherwise the sum of all probabilities could be greater than 1 (imagine again the set diagram of the two events in your head!).

Remarks

R1. Probabilities are often communicated as percentages. So be very careful about typical biases of mass media (and not only!) when dealing with them. We have already warn you, with example, about this trap on page 234.

R2. You must also be very careful with random match probabilities! The most well known case is named the "prosecutor's fallacy". The underlying trap can be understand by considering a crime-scene DNA sample compared against a database of $20,000$ men. A match is found, an individual is then accused and at his trial, it is testified that the probability that two DNA profiles match by chance is only 1 in $10,000$ (prosecutor's argument!). This does not mean the probability that the suspect is innocent is 1 in $10,000$ (what jurors may wrongly understand...)! Since $20,000$ individuals were tested, there were $20,000$ opportunities to find a match by chance (to see the detailed calculation on how to get the probability of getting at least one match based on frequentist approach, see page 659 and page 496 for the bayesian approach).

Let A be an event, P be the probability measure. A has zero probability if $P(A) = 0$. A is impossible if $A = \varnothing$.

Impossibility implies zero probability, but the reverse is false! Consider the real line $\mathbb{R}$; if you randomly select a number x, the probability that $x = 0$ is 0, but this is not impossible. In fact, the probability that x belongs to some countable set, e.g $\mathbb{Q}$, is also 0.

What we mean is that $P(A) = 0$ does not imply $A = \varnothing$, i.e. knowing probability measure $= 0$ does not help you figure out if a set is empty or not!

✍**Example:**

Suppose the typewriter has 50 keys, and the word to be typed is *banana*. If the keys are pressed randomly and independently, it means that each key has an equal chance of being pressed. Then, the chance that the first letter typed is *b* is $1/50$, and the chance that the second letter typed is *a* is also $1/50$, and so on. Therefore, the chance of the first six letters spelling *banana* is:

$$\frac{1}{50}\cdot\frac{1}{50}\cdot\frac{1}{50}\cdot\frac{1}{50}\cdot\frac{1}{50}\cdot\frac{1}{50}=\left(\frac{1}{50}\right)^6=\frac{1}{15625000000} \tag{5.6.48}$$

less than one in 15 billion, but not zero, hence a possible outcome.

From the above, the chance of not typing banana in a given block of 6 letters is $1-(1/50)^6$. Because each block is typed independently, the chance X_n of not typing banana in any of the first n blocks of 6 letters is:

$$X_n=\left(1-\frac{1}{50^6}\right)^n \tag{5.6.49}$$

As n grows, X_n gets smaller. For an n of a million, X_n is roughly 0.9999, but for an n of 10 billion X_n is roughly 0.53 and for an n of 100 billion it is roughly 0.0017. As n approaches infinity, the probability X_n approaches zero; that is, by making n large enough, X_n can be made as small as is desired, and the chance of typing banana approaches 100%.

We will find an example of this kind of disjoint probability in the chapter of Industrial Engineering when studying F.M.E.A. (Failure Modes and Effects Analysis) for fault analysis systems with a complex structure.

In other words in a more general form if $(A_i)_{i\in\mathbb{N}}$ is a sequence of pairwise disjoint events (A_i and A_j can not occur at the same time though $i\neq j$) then:

$$\boxed{P\left(\bigcup_{i=1}^{n}A_i\right)=\sum_{i=1}^{n}P(A_i)} \tag{5.6.50}$$

We then speak of "σ-additivity" because if we look more closely at the three axioms above the measure P forms a σ-algebra (see section Measure Theory page 2483).

At the opposite, if the events are not incompatibles (they can overlap or in other words: they have a joint probability), we then have for probability that at most one of the two takes place:

$$P(A\cup B)=P(A)+P(B)-P(A\cap B) \tag{5.6.51}$$

This means that the probability that at most one of the events A or B occurs is equal to the sum of the probabilities for the realization of A or B occurred, minus the probability that A and B

occurred simultaneously (we will show later that this is simply equal to the probability that the two do not occur at the same time!).

✍**Examples:**

E1. Consider that in a given area, over 50 years, the probability of a major earthquake is 5% and on the same period the probability a major flood is 10%... We would like to know what is the probability that a nuclear plant meets at most one of two events during the same period if the are not incompatibles. We then calculate the probability from the above relation that gives 14.5%...

E2. If we throw a handful of two dices, the probability of getting a double is:

$$P=\frac{6}{36}=\frac{1}{6} \tag{5.6.52}$$

Why ? Because all the possible outcomes at launch give $6^2=36$ issues and the number of favourable cases of double 1, double 2, ... double 6 is 6 and so $P=\frac{6}{6^2}=\frac{6}{36}=\frac{1}{6}$.

And thus if they were incompatibles we would have then $A\cap B=\varnothing$ we find again the disjoint probability:

$$P(A\cup B)=P(A)+P(B) \tag{5.6.53}$$

If we generalize to $n=3$ events we get:

$$\begin{aligned}P(A\cup B\cup C)=&P(A)+P(B)+P(C)\\&-P(A\cap B)-P(A\cap C)-P(B\cap C)\\&+P(A\cap B\cap C)\end{aligned} \tag{5.6.54}$$

The general relation for n events, named the "inclusion-exclusion formula" is:

$$\boxed{\begin{aligned}P\left(\cup_{i=1}^n A_i\right)=&\sum_{i=1}^n P\left(A_i\right)-\sum_{i<j}P\left(A_i\cap A_j\right)+\sum_{i<j<k}P\left(A_i\cap A_j\cap A_k\right)\\&\ldots+(-1)^{n+1}P\left(A_1\cap\ldots\cap A_n\right)\end{aligned}} \tag{5.6.55}$$

In words, we take all possible intersections of one, two, ... n sets and the signs of the sums alternate.

Proof 5.37.2. A point that is in k sets is counted k times by the first sum, C_2^k by the second, C_3^k by the third and so on until it is counted 1 time by the kth term.The net result is:

$$C_1^k-C_2^k+C_3^k+\ldots+(-1)^{k+1}1 \tag{5.6.56}$$

To show that this adds up to 1, we recall the Binomial theorem (see section Calculus page 1364):

$$(a+b)^k=a^k+C_1^k a^{k-1}b+C_2^k a^{k-2}b^2+\ldots+b^k \tag{5.6.57}$$

Setting $a=1$ and $b=-1$ we have:

$$0=1-C_2^k+C_3^k\ldots-(-1)^{k+1}1 \tag{5.6.58}$$

which proves the desired result.

■ Q.E.D.

Remark

This lead us also naturally to "Boole's inequality", that the probability of one or more of events occurring is no greater than the sum of the probabilities of the individual events:

$$P\left(\bigcup_i A_i\right) \leq \sum_i P(A_i) \tag{5.6.59}$$

An immediate consequence of the axioms (A2) and (A3) is the relations between the probability of an event A and its complement, noted $\bar{A}$ (or more rarely in accordance with the notation used in the chapter of Proof Theory the complementary may be noted $\neg A$):

$$P(\bar{A}) = 1 - P(A) \tag{5.6.60}$$

Let U be a universe with a finite number of n possible outcomes:

$$U = \{i_1, i_2, \ldots, i_n\} \tag{5.6.61}$$

where the events:

$$I_1 = \{i_1\}, I_2 = \{i_2\}, I_3 = \{i_3\}, \ldots, I_n = \{i_n\} \tag{5.6.62}$$

are named "elementary events". When these events have the same probability, we say they are "equiprobables". In this case, it is very easy to calculate the probability. Indeed, these events being by definition incompatible with each other at this level of our discussion, we have under the third axiom (A3) of probabilities:

$$P(I_1 \cup I_2 \cup \ldots \cup I_n) = P(I_1) + P(I_2) + \ldots + P(I_n) \tag{5.6.63}$$

but since:

$$P(I_1 \cup I_2 \cup \ldots \cup I_n) = P(U) = 1 \tag{5.6.64}$$

and that the probability of the right hand are by hypothesis equiprobable, we have:

$$P(I_1) = P(I_2) = \ldots = P(I_n) = \frac{1}{n} \tag{5.6.65}$$

Definition (#5.6.106): If A and B are not mutually exclusive but independent, we know that by their (in)compatibility $A \cap B = \varnothing$, that (very important in statistics!):

$$P(A \cap B) = P(A) \cdot P(B) \tag{5.6.66}$$

the probability of the intersection ("and" operator) of two independent events is equal to the product of their probabilities (law of multiplication). We name it "joint probability" (this is the most common case).

✍**Example:**

Consider that in a given area, over 50 years, the probability of a major earthquake is 5% and on the same period the probability a major flood is 10%... Assume that these two events are not mutually exclusive. In other words that they are compatible. We will be interested to their independence. Thus, we would like to know what is the probability that a nuclear power plants meets the two events at the same time, at any time, during this same period. We then calculate the probability from the above equation that gives 0.05%...

Under a more general form, the events $A_1, A_2, \ldots, A_n$ are independent if the probability of the intersection is the product of the probabilities:

$$\boxed{P\left(\bigcap_{i=1}^{n} A_i\right)=\prod_{i=1}^{n} P(A_i)} \tag{5.6.67}$$

Remark

Be careful to not confuse "independent" and "incompatible" (i.e. mutually exclusive)!

So far to summarize a bit we have:

Type	Expression
2 incompatibles events (disjoints)	$P(A\cup B)=P(A)+P(B)$
2 not incompatibles events (joints) non-mutually exclusive events	$P(A\cup B)=P(A)+P(B)-P(A\cap B)$
2 not incompatibles but independents events	$P(A\cap B)=P(A)\cdot P(B)$

Table 5.26: **Classical cases of probabilities**

Thanks the above definition, we can show that the probability that either A or B is to take place (e.g. at least one of the two but not both at the same time), is simply equal to... the probability that the two do not does not occur at the same time:

$$\begin{aligned}P(A\cup B)&=P(A)+P(B)-P\left(A\cap B)\right)\\&=P(A)+P(B)-P(A)P(B)=1-P(\bar{A})P(\bar{B})\\&=1-P(1-A)P(1-B)\end{aligned} \tag{5.6.68}$$

We can also use this definition to determine the probability that only one of two events occurs:

$$\begin{aligned}P(A\oplus B)&=P(A)P(\bar{B})+P(B)P(\bar{A})\\&=P(A)(1-P(B))+P(B)(1-P(A))=P(A)+P(B)-2P(A)P(B)\\&=P(A)+P(B)-2P(A\cap B)\end{aligned} \tag{5.6.69}$$

✍**Example:**

Consider that in a given area, over 50 years, the probability of a major earthquake is 5% and on the same period the probability a major flood is 10%.... We would like to know what is the probability that a nuclear power plant exactly meets one of the both events during the same period, assuming they can not occur at the same time. We then calculate the probability from the above equation and that gives 14%...

There is a common (among others) and important area in the industry where the four following relations are frequently used:

$$\begin{aligned}\text{AND} &= P(A)\cdot P(B)\\ \text{OR COMPATIBLE} &= P(A)+P(B)-P(A\cap B)\\ \text{OR INCOMPATIBLE} &= P(A)+P(B)\\ \text{XOR} &= P(A)+P(B)-2P(A\cap B)\end{aligned} \tag{5.6.70}$$

Remark

Data scientists also use the some of the results above especially when working with proportions in surveys or classification problems (see section Numerical Methods page 6818).

This is the "tree analysis error" or "probabilistic tree analysis" which is used to analyze the possible reasons for failure of a system of any kind (industrial, administrative or other).

To close this part of the chapter consider the following figure displaying Venn diagrams (see section Set Theory page 378) for all 16 events (including the impossible event) that can be described in terms of two given events A and B. In each case, the event is represented by the red area:

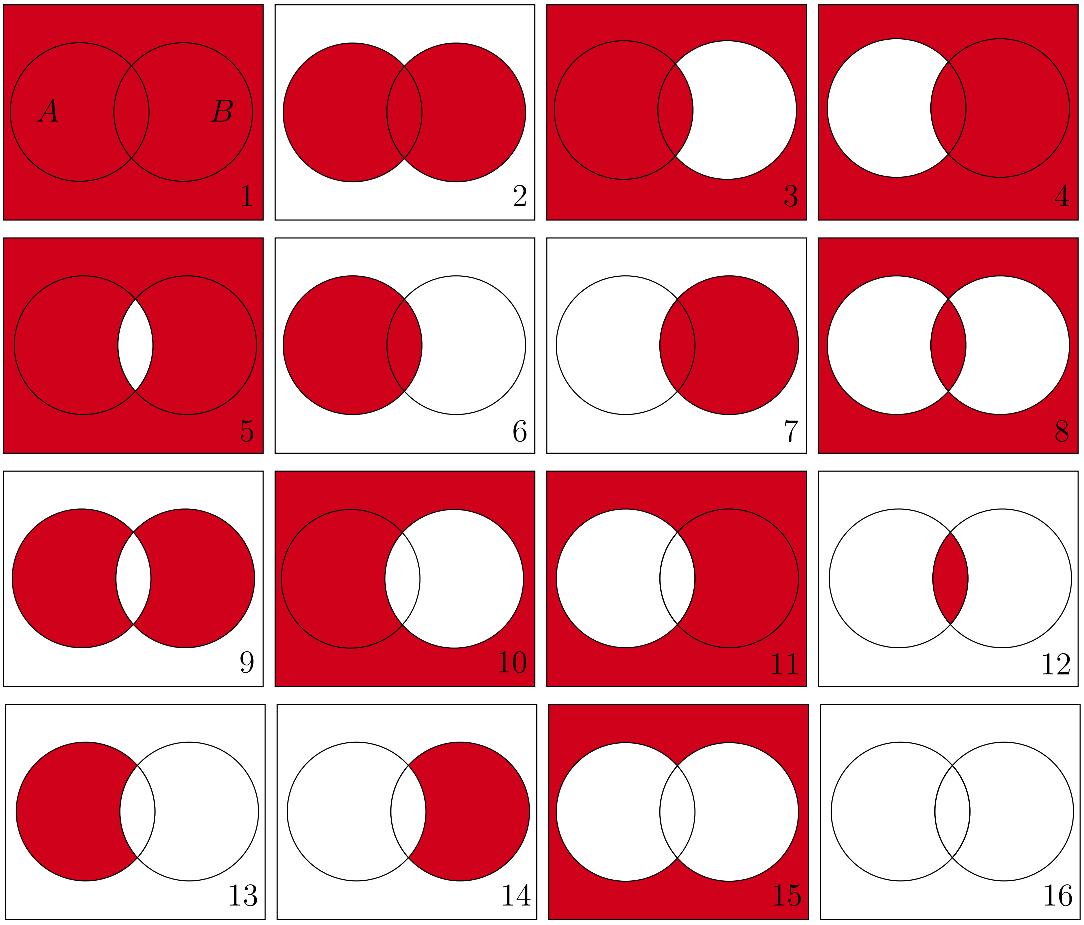

Figure 5.83: Possible Venn diagrams for two events

Consider the situation where A represents and earthquake and B represents a major flood and U the universe of all dramatics events for a nuclear power plant. We consider that the two events are independents. Then each of the 16 events can be described as follows, either mathematically or verbally:

1. An earthquake can occur or a flood or nothing or the both together or any other event (to summarize: any event can occur).
$$P(U)=1=100\% \tag{5.6.71}$$
2. $A\cup B$: Any event with an earthquake a flood or the both event together can occur.
$$P(A\cup B)=P(A)+P(B)-P(A\cap B)=P(A)+P(B)-P(A)P(B) \tag{5.6.72}$$
3. $A\cup B^c$: Any event with earthquake can occur with or without a flood excepted events with a flood not associated to an earthquake.
$$P(A\cup B^c)=P(U)-P(B)+P(A\cap B)=1-P(B)+P(A)P(B) \tag{5.6.73}$$
4. $A^c\cup B$: Any event with earthquake can occur with or without a flood excepted events with a flood not associated to an earthquake.
$$P(A^c\cup B)=P(U)-P(A)+P(A\cap B)=1-P(A)+P(A)P(B) \tag{5.6.74}$$

5. $A^c \cup B^c$: Any event can occur excepted those associated with an earthquake together with a flood.

$$P(A^c \cup B^c) = P(U) - P(A \cap B) = 1 - P(A)P(B) \tag{5.6.75}$$

6. A: Any event with an earthquake can occur (this include the events associating an earthquake and a flood).

$$P(A) = P(A) \tag{5.6.76}$$

7. B: Any event with a flood can occur (this include the events associating a flood and an earthquake).

$$P(B) = P(B) \tag{5.6.77}$$

8. $(A \cap B) \cup (A^c \cap B^c)$: Any event can occur excepted those including an earthquake without a flood or those including a flood without an earthquake.

$$\begin{aligned} P((A \cap B) \cup (A^c \cap B^c)) &= P(U) - P(A) - P(B) + 2P(A \cap B) \\ &= 1 - P(A) - P(B) + 2P(A)P(B) \end{aligned} \tag{5.6.78}$$

9. $(A \cap B^c) \cup (A^c \cup B)$: Any event including an earthquake without a flood or a flood without an earthquake can occur.

$$P((A \cap B^c) \cup (A^c \cup B)) = P(A) + P(B) + 2P(A \cap B) \tag{5.6.79}$$

10. B^c: Any event excepted those including a flood can occur.

$$P(B^c) = P(U) - P(B) = 1 - P(B) \tag{5.6.80}$$

11. A^c: Any event excepted those including an earthquake can occur.

$$P(A^c) = P(U) - P(A) = 1 - P(A) \tag{5.6.81}$$

12. $A \cap B$: Any events associating an earthquake and a flood together can occur.

$$P(A \cap B) = P(A)P(B) \tag{5.6.82}$$

13. $A \cap B^c$: Any event with an earthquake and without a flood can occur.

$$P(A \cap B^c) = P(A) - P(A)P(B) \tag{5.6.83}$$

14. $A^c \cap B$: Any event with a flood and without an earthquake can occur.

$$P(A^c \cap B) = P(B) - P(A)P(B) \tag{5.6.84}$$

15. $A^c \cap B^c$: Any event can occur excepted those including an earthquake and/or a flood.

$$P(A^c \cap B^c) = P(U) - P(A \cup B) = 1 - P(A) - P(B) - P(A)P(B) \tag{5.6.85}$$

16. $A \cap A^c$ or $B \cap B^c$: Impossible Event.

$$P(A \cap A^c) = P(B \cap B^c) = P(\varnothing) = 0 \tag{5.6.86}$$

5.6.3 Conditional Probabilities

What can we infer about the probability of an event B knowing that an event A has occurred, aware that there is a link between A and B? In other words, if there is a link between A and B, the completion of A has to change our understanding of B and we want to know if it is possible to define the conditional probability of an event (relatively) to another event.

This type of probability is named "conditional probability" or "a posterior probability" of B knowing A, and is denoted in the context of the study of conditional probabilities:

$$P(B/A) \tag{5.6.87}$$

and often in practice to avoid confusion with a possible division:

$$P(B \mid A) \tag{5.6.88}$$

and we sometimes find in U.S. books the notation:

$$P(B \wedge A) \tag{5.6.89}$$

or also:

$$P_B(A) \tag{5.6.90}$$

We also have the case:

$$P(A/B) \tag{5.6.91}$$

which is named "likelihood function of A" or "a priori probability of A given B".

Historically, the first mathematician to have used the correct notion of conditional probability was Thomas Bayes (1702-1761). This is why we often say "Bayes" or "Bayesian" probabilities as soon as conditional probabilities are involved: "Bayes formula", "Bayesian statistics", etc.

The notion of conditional probability that we will introduce is much less simple than it first appears and the conditionals problems are an inexhaustible source of errors of any kind (there are famous paradoxes on the subject and even expert requires peer review to minimize mistakes).

Let's start with a simple example: Suppose we have two dice. Now imagine that we only launched the first die. We want to know what is the probability that by throwing the second dice, the sum of the two numbers is equal to a given minimum value. Thus, the probability of obtaining the minimum value given the value of the first die is totally different from the probability of obtaining the same minimum value in throwing two dice at the same time. How to calculate this new probability?

Let us now formalize the process! After the launch of the first dice, we have:

$$A = \{\text{the result of the first throw is...}\} \tag{5.6.92}$$

Under the hypothesis that $B \subset A$, we feel that $P(B/A)$ must be proportional to $P(B)$, the proportionality constant being determined by the normalization:

$$P(A/A) = 1 \tag{5.6.93}$$

Now let $B\subset A^c$ (B is included in the complement of A so that the events are mutually exclusive). It is then relatively intuitive .... that under the previous hypothesis of incompatibility we have the conditional probability:

$$P(B/A)=0 \tag{5.6.94}$$

This leads us to the following definitions of respectively a posteriori and a priori probabilities:

$$\boxed{P(B/A)=\dfrac{P(A\cap B)}{P(A)}}\quad \text{and}\quad \boxed{P(A/B)=\dfrac{P(A\cap B)}{P(B)}} \tag{5.6.95}$$

Thus, the fact to know that A has occurred reduces all possible outcomes of the universe U of B. From there, only the events of type $A\cap B$ are important. The probability of A given B or vice versa (by symmetry) must be proportional to $P(A\cap B)$!

The coefficient of proportionality is the denominator and it ensures the certain event. Indeed, if two events A and B are independent (think the black cat and the scale for example), then we have:

$$P(A\cap B)=P(A)P(B) \tag{5.6.96}$$

and then we see that $P(B/A)$ is equal to $P(B)$ and therefore the event A adds no information to B and vice versa! So in other words, if A and B are independent, we have:

$$P(B/A)=P(B)\quad \text{and}\quad P(A/B)=P(A) \tag{5.6.97}$$

Another fairly intuitive way to see things is to represent the probability measure P as a measure of subsets areas (surface) of $\mathbb{R}^2$.

Indeed, if A and B are two subsets of respective areas $P(A)$ and $P(B)$ then the question of what is the probability that a point in the plane belongs to B knowing that it belongs to A it is quite obvious that the probability is given by answer:

$$\frac{\text{Surface}(A)\cap\text{Surface}(B)}{\text{Surface}(A)} \tag{5.6.98}$$

We would like to indicate that the definition of conditional probability is often used in the following way:

$$P(A\cap B)=P(A/B)P(B)=P(B/A)P(A) \tag{5.6.99}$$

named "formula of compound probabilities" or "product rule". It is written in many different ways (just a matter of notation convention):

$$P(A\cap B)=P(A/B)P(B)\qquad \text{or}\qquad P(A,B)=P(A|B)P(B) \tag{5.6.100}$$

Thus, the a posteriori probability of B knowing A can also be written as:

$$\boxed{P(B/A)=\frac{P(A/B)P(B)}{P(A)}} \tag{5.6.101}$$

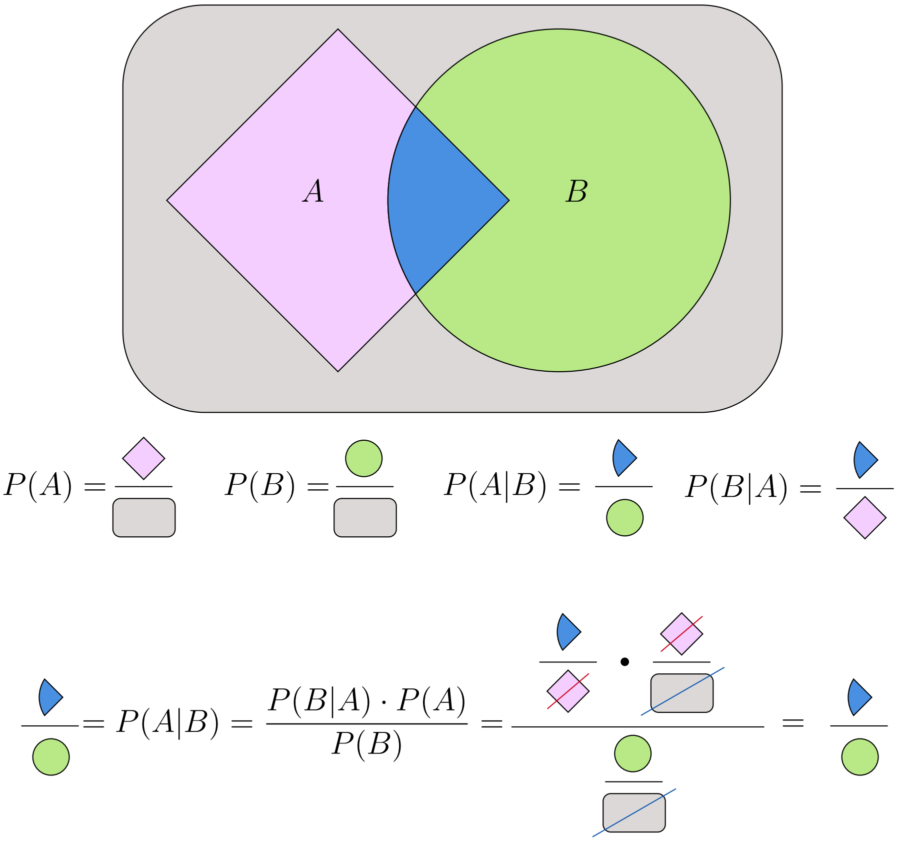

Figure 5.84: Bayes' theorem illustrated

Or in human words:

$$\text{Posterior probability} = \frac{\text{Likelihood} \cdot \text{prior probability}}{\text{expectedness}} \tag{5.6.102}$$

but also sometimes:

$$\text{Plausability} = \frac{\text{Likelihood} \cdot \text{Credence}}{\text{Partition function}} \tag{5.6.103}$$

The way that this formula gives an update of the probability hypothesis, B, in light of some body of data, A, is named the "diachronic interpretation". "Diachronic" meaning that something is happening over time, in this case the probability of the hypothesis changes, over time, as we see new data.

In this interpretation the different terms have a name:

- $P(B)$ is the probability of the hypothesis before we see the data, name as we already know, the "prior probability[29]", or just the "prior".
- $P(B/A)$ is what we want to compute, the probability of the hypothesis after we see the data, named as we already know, the "posterior".

---

[29] Where does the prior come from is the million dollar question... In principle the bayesian is supposed to choose a prior that represents their prior information. This will be challenging in high dimensional cases to say the least. Also, critics will say that someone's prior opinions should not be included in a data analysis because this is not scientific.

- $P(A/B)$ is the probability of the data under the hypothesis, named the "likelihood".
- $P(A)$ is the probability of the data under the hypothesis, named the "normalizing constant" or "expectedness".

✍Examples:

E1. Let us consider a disease like meningitis. The priori probability of having the meningitis will be denoted by $P(M) = 0.001$ (arbitrary value for the example) and the expectedness of having headache will be denoted $P(S) = 0.1$. We assume known that the likelihood of having a headache if we have meningitis is:

$$P(S/M) = 0.9 \tag{5.6.104}$$

So we will use the Bayes' theorem:

$$\underbrace{P(A/B)}_{\text{posterior probability}} = \frac{\overbrace{P(B/A)}^{\text{Likelihood}} \cdot \overbrace{P(A)}^{\text{prior probability}}}{\underbrace{P(B)}_{\text{expectedness}}} \tag{5.6.105}$$

The Bayes' theorem then gives the a posteriori probability of having meningitis if we have a headache:

$$P(M/S) = \frac{P(S/M)P(M)}{P(S)} = 0.09 \tag{5.6.106}$$

E2. In a quiz-show (this example is named the Monty Hall paradox), the candidate has to select one of three doors. Behind two doors there is a goat (an undesirable prize). Behind the one door there is a car. At the beginning the candidate tries to guess the door with the car. Afterwards the moderator Monty Hall opens one of the doors with a goat which is not the candidate's door. So two doors are left where one of them is the one, the candidate has chosen. Monty asks the candidate whether he would like to change his mind; he is free to select the other door.

In general, is it better to change the mind, stick to the first selection or doesn't it matter?

Assumption (one of three cases): The candidate selects door #1.

D_1	Car behind door #1
D_2	Car behind door #2
D_3	Car behind door #3

We define the corresponding probabilities:

$$P(D_1) = \frac{1}{3} \qquad P(D_2) = \frac{1}{3} \qquad P(D_3) = \frac{1}{3} \tag{5.6.107}$$

We somehow have to model the behaviour of the moderator. Therefore we introduce a hypothesis H that he opens door #3. The probability that he selects door #3 in favour of door #2 is $\frac{1}{2}$, because #1 is already taken by the candidate:

$$P(H) = \frac{1}{2} \tag{5.6.108}$$

Furthermore:

$$P(H/D_1)=\frac{1}{2} \qquad P(H/D_2)=1 \qquad P(H/D_3)=0 \tag{5.6.109}$$

So the probability that he opens door #3 under the condition that door #1 contains the car is $\frac{1}{2}$. The probability is 1 if the car is in door #2. And if the car is in door #3, the moderator will never show door #3.

The above scenario can be build easily with a software like @Risk of Palisade (the PrecisionTree module):

In the above figure we assume that the contester has already chooses door #1. If the car is behind door #1 Monty well flip a coin to open door #2 or #3 (hence the 50% and 50%). However if the car is behind door #2 Monty will surely open door #3 (hence the 100%). And finally if the car is behind door #3 Monty will surely open door #2 (hence the second 100%).

We can spot some asymmetry here. This point is evidently responsible why an intuition like *it does not matter* might be wrong.

So we will use the Bayes' Theorem:

$$\underbrace{P(A/B)}_{\text{posterior probability}} = \frac{\overbrace{P(B/A)}^{\text{Likelihood}} \cdot \overbrace{P(A)}^{\text{prior probability}}}{\underbrace{P(B)}_{\text{expectedness}}} \tag{5.6.110}$$

The important question is: Under the assumption that we have selected door #1 (our first assumption) and Monty opens door #3 (our hypothesis or expectedness), what is the probability that the car is behind door #1 compared to door #2?

$$P(D_1|H) = \frac{P(H|D_1) \cdot P(D_1)}{P(H)} = \frac{\frac{1}{2} \cdot \frac{1}{3}}{\frac{1}{2}} = \frac{1}{3} \tag{5.6.111}$$

$$P(D_2|H) = \frac{1 \cdot \frac{1}{3}}{\frac{1}{2}} = \frac{2}{3} \tag{5.6.112}$$

So apparently, the probability that door #2 contains the car is higher than for door #1. Or in other words: in this case the candidate should prefer to change his mind.

Now we have to evaluate this for other hypotheses (moderator opens door #2) and other candidate selections (door #2 and door #3). The approach is the same and not carried out here. But the conclusion keeps the same in all cases: Being open to change your mind will make you probabilistically win the car.

So here Bayes rule is necessary because the contester needs to flip the tree above. To get the nodes in the opposite order. The reason is that the contester will first see the door that Monty opens. At that point the contester need to know the posterior probability. In @Risk Palisade has a Bayes revision option that flips the tree and gives:

Now Monty action is on the left and the location is on the right. Can you see that the contester should switch no matter what Monty does? Monty won't certainly open door 1 because the contester has already chosen it. You can see on the left that the chance are 50/50 that Monty opens door #2 or door #3. If he opens door #2 the posterior probability that the car is behind door #3 is $2/3$ that is twice the probability which is twice the posterior probability that it is behind door #1. In the same way if he opens door #3, the posterior probability that the car is behind door #2 is $2/3$ that is twice the probability which is twice the posterior probability that it is behind door #1.

Some people think that this analysis is all smoke and mirrors. In fact some people continue to believe that Bayes rule is quite controversial. However everything here is based on mathematical ground and there is nothing controversial about it. The key about understanding the apparent paradox, that the contester can do better by switching, is that Monty has supplied some useful information by showing a door where the car is not located. This information together with Bayes rule allow the contester to improve his chances of winning the car by switching doors.

We also notice that:

$$\begin{aligned}P(A)&=P\left((B_1\cup B_2\cup\ldots\cup B_i)\cap A\right)\\&=P\left((B_1\cap A)\cup(B_2\cap A)\cup\ldots\cup(B_i\cap A)\right)\\&=P\left((B_1\cap A)+(B_2\cap A)+\ldots+(B_i\cap A)\right)\\&=P(A/B_1)P(B_1)+P(A/B_2)P(B_2)+\ldots+P(A/B_n)P(B_n)\\&=\sum_{i=1}^{n}P(A/B_i)P(B_i)\end{aligned}\tag{5.6.113}$$

So we can know the probability of the event A knowing the elementary probabilities $P(B_i)$ of its causes and the conditional probabilities of A for each B_i:

$$\boxed{P(A)=\sum_{i=1}^{n}P(A/B_i)P(B_i)}\tag{5.6.114}$$

which is named the "formula of total probabilities" or "total probabilities theorem" (relation that is also very useful when we don't know the value of $P(A)$ or can't estimate it directly easily). But also, for any j, we have the following corollary using the previous results that gives us following an event A, the probability that it is the cause B_i that produced it:

$$\boxed{P(B_j/A)=\frac{P(B_j\cap A)}{P(A)}=\frac{P(A/B_j)P(B_j)}{\displaystyle\sum_i P(A/B_i)P(B_i)}}\tag{5.6.115}$$

which is the general form of the "Bayes formula" or "Bayes' theorem" that we will use a little in the Statistical Mechanics chapter and through the study of the queueing theory (see section Quantitative Management page 8141). You should know that the implications of this theorem are, however, considerable in daily life, in medicine, in industry and in the field of Data Mining.

In fact, every valid form of hypothetico-deductive method (HDM) is described by Bayes' theorem. The hypothetico-deductive method consists of formulating a hypothesis H, deducing the observations that would be made if H were true and those that would be made if H were false, and making numerous observations until the probability of H far exceeds all known alternatives, or becomes implausible.

We often find in the literature many examples of applications of the previous relation with only two possible outcomes B with respect to the event A. Therefore we find the Bayes formula written in the following form for each issue:

$$\begin{aligned}P(B_1/A)&=\frac{P(A/B_1)P(B_1)}{P(A/B_1)P(B_1)+P(A/B_2)P(B_2)}=\frac{P(A/B_1)P(B_1)}{P(A/B_1)P(B_1)+P(A/\bar{B}_1)P(\bar{B}_1)}\\P(B_2/A)&=\frac{P(A/B_2)P(B_2)}{P(A/B_1)P(B_1)+P(A/B_2)P(B_2)}=\frac{P(A/B_2)P(B_2)}{P(A/\bar{B}_2)P(\bar{B}_2)+P(A/B_2)P(B_2)}\end{aligned}\tag{5.6.116}$$

and note that in this particular case (binary outcomes):

$$\begin{aligned}
P(B_1/A)+P(B_2/A) &= P(B_1/A)+P(\bar{B}_1/A)\\
&= \frac{P(A/B_1)P(B_1)}{P(A/B_1)P(B_1)+P(A/\bar{B})P(\bar{B})}+\frac{P(A/B_2)P(B_2)}{P(A/\bar{B}_2)P(\bar{B}_2)+P(A/B_2)P(B_2)}\\
&= \frac{P(A/B_1)P(B_1)}{P(A/B_1)P(B_1)+P(A/\bar{B})P(\bar{B})}+\frac{P(A/B_2)P(B_2)}{P(A/B_1)P(B_1)+P(A/\bar{B}_1)P(\bar{B}_1)}\\
&= \frac{P(A/B_1)P(B_1)+P(A/B_2)P(B_2)}{P(A/B_1)P(B_1)+P(A/\bar{B}_1)P(\bar{B}_1)}\\
&= \frac{P(A/B_1)P(B_1)+P(A/\bar{B}_1)P(\bar{B}_1)}{P(A/B_1)P(B_1)+P(A/\bar{B}_1)P(\bar{B}_1)}=1
\end{aligned} \tag{5.6.117}$$

is an intuitive result.

For binary events, we also have (returning to the theorem of total probabilities seen above):

$$\begin{aligned}
P(A) &= \sum_{i=1}^{n} P(A/B_i)P(B_i)\\
&= P(A/B_1)P(B_1)+P(A/B_2)P(B_2)\\
&= P(A/B_1)P(B_1)+P(A/\bar{B}_1)P(\bar{B}_1)
\end{aligned} \tag{5.6.118}$$

Or in the case of odds ratio:

$$\frac{P(A/B)}{P(\bar{A}/B)}=\frac{\dfrac{P(B/A)P(A)}{P(B)}}{\dfrac{P(B/\bar{A})P(\bar{A})}{P(B)}}=\frac{P(B/A)P(A)}{P(B/\bar{A})}\frac{P(A)}{P(\bar{A})} \tag{5.6.119}$$

✍**Examples:**

E1. A disease affects 10 people on $10,000$ ($0.1\% = 0.001$). A test has been developed which has a 5% false positives (people not having the disease but for which the test says they are affected) but still always detects the disease if a person has it. What is the probability that a random person for which the test gives a positive result really has this disease?

There is therefore $10,000$ people, 500 of which are false positives, and we know a posteriori that 10 people have really the disease. Then the probability that somebody who has a positive test result is really sick is:

$$\begin{aligned}P(M)&=0.001\\P(\bar{M})&=0.999\\P(T/M)&=1\\P(T/\bar{M})&=0.05\\P(T)&=P(T/M)P(M)+P(T/\bar{M})P(\bar{M})=0.05095\\P(M/T)&=\frac{P(T/M)P(M)}{P(T)}=\frac{1\cdot 0.001}{0.05095}=0.19627\end{aligned}\tag{5.6.120}$$

This is often a shocking and counter-intuitive result. It also highlights why diagnostic tests must be extremely reliable!

E2. Two machines M_1 and M_2 produce respectively 100 and 200 pieces. M_1 produces 5% defective pieces and M_2 produces 6% (posterior probabilities). What is the a priori probability that a defective piece was manufactured by the machine M_1?

We then have:

$$\begin{aligned}P(M_j/A)&=\frac{P(A/M_j)P(M_j)}{\sum\limits_i P(A/M_i)P(M_i)}=\frac{P(A/M_1)P(M_1)}{P(A/M_1)P(M_1)+P(A/M_2)P(M_2)}\\&=\frac{\dfrac{5}{100}\dfrac{300}{100}}{\dfrac{5}{100}\dfrac{100}{300}+\dfrac{6}{100}\dfrac{200}{300}}=\frac{5\%\dfrac{1}{3}}{5\%\dfrac{1}{3}+6\%\dfrac{2}{3}}\cong 39\%\end{aligned}\tag{5.6.121}$$

E3. From a batch of 10 pieces with 30% defective, we take a sample of size 3 without replacement. What is the probability that the second piece is correct (whatever the first is)?

We have (as the problem is binary, i.e. correct/not correct):

$$\begin{aligned}P(A)&=\sum_{i=1}^{n}P(A/B_i)P(B_i)=\sum_{i=1}^{2}P(A/B_i)P(B_i)\\&=P(A/B_1)P(B_1)+P(A/B_2)P(B_2)=\frac{7}{9}\frac{3}{10}+\frac{6}{9}\frac{7}{10}=70\%\end{aligned}\tag{5.6.122}$$

E4. Consider that two duelists (A and B) have a revolver with a rotatable magazine and they want to play the russian roulette game. The magazine contains 6 slots, and the duelists load it with one shot (S):

1. Duelist A rotates the magazine at random, points the revolver at his/her head and presses the trigger (we consider that the rotation of the magazine is completely fair).
2. If duelist A survives, he/she hands the revolver to duelist B who repeats step 1 above.

3. The duelists continue in this manner until one of them are dead.

What is the probability that duelist A dies as he/her starts the game ?

As it is a binary case so too as the previous example, we can write ($P\left(A/S\right)$ is the conditional probability of A dies given the first slot contains the shot and $P\left(A/\bar{S}\right)$ is interpreted that duelist B begins the game again as duelist A didn't get the kill shot):

$$\begin{aligned} P(A) &= \sum_{i=1}^{n} P(A/S_i)P(S_i) = P\left(A/S\right)P\left(S\right) + P\left(A/\bar{S}\right)P\left(\bar{S}\right) \\ &= 1\frac{1}{6} + P\left(A/\bar{S}\right)\frac{5}{6} \\ &= \frac{1}{6} + P(B)\cdot\frac{5}{6} = \frac{1}{6} + (1-P(A))\frac{5}{6} \end{aligned} \tag{5.6.123}$$

Therefore solving this last line (equation with one unknown):

$$P(A) = \frac{1}{6} + \frac{5}{6} - \frac{5}{6}P(A) \Rightarrow \frac{11}{6}P(A) = 1 \Rightarrow P(A) = \frac{6}{11} = 54.\overline{54}\% \tag{5.6.124}$$

Hence the duelist that starts the game is more likely to die than the first (that makes quite sense as this duelist will always have one shot more in advance).

E5. Consider that corporations assess employees knowledge with exams or assessments in the form of multiple choice questions (MCQs). If an employee responds to a question there are two issues: either he knows the answer or he try to guess it. Let p be the probability that the employee know the answer and therefore $1-p$ that he guess it. We admit that the employee who guesses will correctly answer with a probability of $1/m$ where m is the number of proposed answers. What is the a priori probability that an employee (really) knows the answer to a question with 5 choices if he answered correctly?

Let B and A be respectively the events "the employee knows the answer" and "the employee correctly answers the question". Then the a priori probability that an employee knows (really) the answer to a question that he answered correctly is:

$$P(B/A) = \frac{P(A/B)P(B)}{P(A/B)P(B) + P(A/\bar{B})P(\bar{B})} = \frac{1\cdot p}{1\cdot p + \dfrac{1}{m}(1-p)} = \frac{5}{6} \cong 83\% \tag{5.6.125}$$

E6. Suppose a doctor thinks the odds are $2/1$ that a patient has a certain disease. She orders two independents tests. Let H be the event the patient has the disease and E_1 and E_2 be the event the tests are positive. Suppose the first test has probability 0.1 of a false positive and probability 0.05 of a false negative. The second test has probabilities 0.05 and 0.08 of a false positive and false negative, respectively. If both tests are positive, what is the posterior probability the patient has the disease?

Assuming that E_1 and E_2 are conditionally independent of H and also of $\bar{H}$, we work first in terms of odds, then convert to probability:

$$\frac{P(H/E_1E_2)}{P(\bar{H}/E_1E_2)}=\frac{P(H)}{P(\bar{H})}\frac{P(E_1E_2/H)}{P(E_1E_2/\bar{H})}=\frac{P(H)}{P(\bar{H})}\frac{P(E_1/H)P(E_2/H)}{P(E_1/\bar{H})P(E_2/\bar{H})} \tag{5.6.126}$$

The data are:

$$\frac{P(H)}{P(\bar{H})}=2, P(E_1/H)=0.95, P(E_1/\bar{H})=0.1, P(E_2/H)=0.92, P(E_2/\bar{H})=0.05 \tag{5.6.127}$$

Substituting value, we get:

$$\frac{P(H/E_1E_2)}{P(\bar{H}/E_1E_2)}=2\cdot\frac{0.95\cdot 0.92}{0.10\cdot 0.05}=349.6 \tag{5.6.128}$$

Similarly we get:

$$P(H/E_1E_2)=99.71\% \tag{5.6.129}$$

E7. Let us come back again on prosecutor's fallacy with the DNA case (see earlier above page 477). Let us consider that DNA profiling of a suspect gives rise to a rare trait, X, such that:

$$P(X\text{occurs in general population})=\frac{1}{10000} \tag{5.6.130}$$

which is equivalent to:

$$P(\text{Match}/\text{Innocent})=P(\text{M}/\text{I})=\frac{1}{10000} \tag{5.6.131}$$

This is of no interest! We want (G is for "potential guilty"):

$$P(\text{I}/\text{M})=\frac{P(\text{M}/\text{I})P(\text{I})}{P(\text{M}/\text{I})P(\text{I})+P(\text{M}/\text{G})P(\text{G})}=\frac{\dfrac{1}{10000}\dfrac{19999}{20000}}{\dfrac{1}{10000}\dfrac{19999}{20000}+1\cdot\dfrac{1}{20000}}\cong 66.67\% \tag{5.6.132}$$

Caution! Be careful when reading books containing probabilities calculations especially when the authors are theists and even more when the probabilities involve Bayes' theorem. The believing physicist Stephen Unwin, as presented in his 12003 (holocene calendar) book, calculates the probability of his christian god to be 67%. He begins his calculation by assuming the prior probability of christian god's existence, before any evidence is considered, to be 50%... How does he know that when we know that there are thousands of very different gods existing on Earth? If we compare Unwin's calculation with the unpublished one of the non-believing physicist Larry Ford. Ford used all the same equations as Unwin, differing only in the numbers inserted in the calculation. He argued the prior probability of Unwin's christian god must be compared with other unobserved entities such as Big Foot or the Loch Ness Monster, which he took to be one in a million (10^{-6}). With his set of numbers, Ford's conclusion was that the probability christian god exists is one in a hundred thousand trillion (10^{-17}).

Bayesian analysis provides also a powerful tool to formalize reasoning under uncertainty and the examples we have shown above illustrate how this tool can be difficult to use.

Finally, for a future use in the section of Theoretical Computing, for the Data Mining technique named "binomial naive Bayes classification" we will need a last result!

Let us recall the product rule seen just earlier above:

$$P(A\cap B)=P(A/B)P(B) \tag{5.6.133}$$

We can extend this for three variables. Indeed, let us consider:

$$P(A\cap D)=P(A/D)P(D) \tag{5.6.134}$$

and let us put $D=B\cap C$ then:

$$P(A\cap (B\cap C))=P(A/(B\cap C))P(B\cap C) \tag{5.6.135}$$

But as the product rule gives us also:

$$P(B\cap C)=P(B/C)P(C) \tag{5.6.136}$$

Then:

$$P(A\cap (B\cap C))=P(A/(B\cap C))P(B/C)P(C) \tag{5.6.137}$$

also sometimes denoted:

$$P(A,B,C)=P(A|B,C)P(B|C)P(C) \tag{5.6.138}$$

and in general for n variables:

$$\boxed{P(A_1,A_2,\ldots,A_n)=P(A_1|A_2,\ldots,A_n)P(A_2|A_3,\ldots,A_n)P(A_{n-1}|A_n)P(A_n)} \tag{5.6.139}$$

In general we refer to this as the "chain rule" or to avoid any confusion with the same term in the field of Differential and Integral Calculus we refer to this as the "Bayes' chain rule".

This formula is especially significant for Bayesian Belief Nets. It provides a means of calculating the full joint probability distribution ; in BBNs many of the variables A_i will be conditionally independent.

Now the reader must keep something in mind: Any probability result that is true for unconditional probability remains true if everything is conditioned on some event!

We know that by definition:

$$P(A/B)=\frac{P(A\cap B)}{P(B)} \tag{5.6.140}$$

and so if we condition everything on C having occurred, we get that:

$$P(A/(B\cap C))=\frac{P((A\cap B)/C)}{P(B/C)} \tag{5.6.141}$$

Hence:

$$P((A\cap B)/C)=P(A/(B\cap C))P(B\cap C) \tag{5.6.142}$$

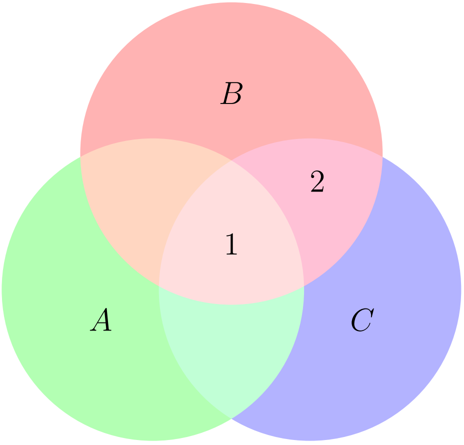
also sometimes (badly) denoted:

$$P(A,B/C)=P(A/B,C)P(B/C) \tag{5.6.143}$$

or:

$$P(A,B|C)=P(A|B,C)P(B|C) \tag{5.6.144}$$

Intuitively to get this result it can help to draw the corresponding Venn diagram (almost as always):



We then have:

$$P(A\cap B/C)=\frac{\text{"1"}}{\text{"C"}},\quad P(B/C)=\frac{\text{"1"}+\text{"2"}}{\text{"C"}},\quad P(A/B\cap C)=\frac{\text{"1"}}{\text{"1"}+\text{"2"}} \tag{5.6.145}$$

and then just do the multiplications to see that everything is fine.

5.6.3.1 Conditional Expectation and Variance

Now, we will see the continuous version of the conditional probability by introducing the subject directly with a particular example (the general theory being indigestible) infinitely important in the field of social statistics and quantitative finance. However, this choice (the study of a particular case) implies that the reader has read the first chapter of Statistics to study the functions of continuous distributions and especially that of the Pareto law.

So here's the scenario: Often, in social sciences or economics, we find in the literature dealing with the laws of Pareto statements like the following (but almost never with a detailed proof): whatever your income, the average income of those who have an income above yours is in a constant ratio, greater than 1, to your income if it follows a Pareto random variable. Then we say that the law is isomorphic to any truncated part itself.

Let's see what it is exactly!

Let X be a random variable equal to the income and following a Pareto with the density (see section Statistics page 746):

$$f(x)=k\frac{x_m^k}{x^{k+1}} \tag{5.6.146}$$

with $k>1,x_m>0,x\geq x_m$ and that has for distribution function (see also the Statistics chapter for the detailed proof):

$$P(X\leq x)=1-\left(\frac{x_m}{x}\right)^k \tag{5.6.147}$$

The sentence begins with «*whatever your income* ...», then select any income $x_0\geq x_m$.

Now we need to compute «*the average income of those with income higher than* x_0». It is therefore asked to calculate the expected (average income) of a new random variable Y that is equal to X, but restricted to the population of people with an income above x_0:

$$Y=X|_{\{X\geq x_0\}} \tag{5.6.148}$$

The distribution function of Y is given by:

$$P(Y\leq x)=P\left(X\leq x \mid X\geq x_0\right) \tag{5.6.149}$$

This expression is of course equal to zero if $x\leq x_0$. Well, so far we have only do vocabulary. First recall the following conditional probability relation already seen before:

$$P(B/A)=\frac{P(A\cap B)}{P(A)} \tag{5.6.150}$$

for $x\geq x_0$ we have for the conditional law:

$$\boxed{P\left(X\leq x \mid X\geq x_0\right)=\frac{P(x_0\leq X\leq x)}{P(X\geq x_0)}} \tag{5.6.151}$$

Before going further, you should be aware that the numerator and denominator are independent but that the whole must be considered, however, as the realization of a single random variable which we denote Y. Furthermore, only the numerator is a dependent variable. The denominator can it be considered as a normalization constant.

So we see that the density of Y is given by the function:

$$f_Y(y)=\begin{cases} 0 & y<x_0 \\ \dfrac{f(y)}{P(X\geq x_0)} & y\geq x_0 \end{cases}$$

Now we can calculate the expected mean (see section Statistics page 634) of Y (assuming $X\geq x_0$):

$$\begin{aligned}\mathrm{E}(Y)=\mathrm{E}(Y|X\geq x_0)&=\int yf_Y(y)\mathrm{d}y=\int\limits_{x_0}^{+\infty}\frac{f(y)}{P(X\geq x_0)}\mathrm{d}y=\frac{1}{P(X\geq x_0)}\int\limits_{x_0}^{+\infty}yf(y)\mathrm{d}y\\ &=\frac{1}{P(X\geq x_0)}\int\limits_{x_0}^{+\infty}y\frac{x_m^k}{y^{k+1}}\mathrm{d}y=\frac{kx_m^k}{P(X\geq x_0)}\int\limits_{x_0}^{+\infty}\frac{1}{y^k}\mathrm{d}y\\ &=\frac{kx_m^k}{P(X\geq x_0)}\frac{1}{(k-1)y^{k-1}}\Bigg|_{x_0}^{+\infty}=\frac{1}{P(X\geq x_0)}\frac{kx_m^k}{(k-1)x_0^{k-1}}\end{aligned}\tag{5.6.152}$$

Knowing that (see section Statistics page 750):

$$P(X\geq x_0)=\int\limits_{x_0}^{+\infty}k\frac{x_m^k}{x^{k+1}}\mathrm{d}x=\frac{x_m^k}{x_0^k}=\left(\frac{x_m}{x_0}\right)^k\tag{5.6.153}$$

We finally have:

$$\mathrm{E}(Y)=\frac{k}{k-1}x_0\tag{5.6.154}$$

$\mathrm{E}(Y)$ represents also the average income of those with a income above x_0 and as can be seen from the above equality it is in a constant ratio, greater than 1, to your income x_0.

We can check this result by doing a Monte Carlo simulation in a spreadsheet software (it is interesting to mention it to generalize to situations not computable by hand). You just need to simulate the inverse of the distribution function:

$$X=\left(\frac{x_m^k}{1-P(X\leq x)}\right)^{1/k}\tag{5.6.155}$$

in Microsoft® Excel® 11.8346:

```
=($B$7^$B$6/(1-RANDBETWEEN(1,10000)/10000))^(1/$B$6)
```

and then take the average of the values obtained above or equal to a given X (which corresponds to x_0) and ensure that we get the good results as proved above!

Therefore, generally for a discrete variable, the "conditional mean" or "conditional expectation" is commonly defined by:

$$\mathrm{E}(X|Y)(y) \equiv \mathrm{E}(X|Y=y) \equiv \sum_x x \cdot P(X=x|Y=y) \tag{5.6.156}$$

But this is only the case when we take an equality with the prior variable! If we generalize it to any other order relation, then a better definition would be:

$$\boxed{\mathrm{E}(X|Y\mathcal{R}y) \equiv \sum_x x \cdot P(X=x|Y\mathcal{R}y)} \tag{5.6.157}$$

Obviously, we could also calculate the conditional variance (verbatim the conditional standard deviation) as we will see it further below!

Theorem 5.38. Let us prove now a property that will be useful to us especially during our study of financial time series. It is based on the fact that sometimes we have to calculate such relations:

$$\boxed{\mathrm{E}\left(\mathrm{E}(X|Y)(y)\right) = \mathrm{E}(X)} \tag{5.6.158}$$

that are named "iterated conditional mean" or "law of total expectation" (and even sometimes named the "tower rule"...) also sometimes denoted $\mathrm{E}\left(\mathrm{E}(X|Y=y)\right)$ or $\mathrm{E}\left(\mathrm{E}(X|\pi)\right)$.

Proof 5.38.1.

$$\begin{aligned}\mathrm{E}\left(\mathrm{E}(X|Y)\right) &= \sum_y \mathrm{E}(X|Y=y)\cdot P(Y=y)\\ &= \sum_y\left(\sum_x x\cdot P(X=x|Y=y)\right)\cdot P(Y=y)\\ &= \sum_y\sum_x x\cdot P(X=x|Y=y)\cdot P(Y=y)\\ &= \sum_y\sum_x x\cdot P(Y=y|X=x)\cdot P(X=x)\\ &= \sum_x x\cdot P(X=x)\cdot\left(\sum_y P(Y=y|X=x)\right)\\ &= \sum_x x\cdot P(X=x)\\ &= \mathrm{E}(X)\end{aligned} \tag{5.6.159}$$

■ Q.E.D.

Let us do the same for the variance (see section Statistics page 634)! First let us recall the definition of the variance (or "unconditional variance"). If Y is a random variable, and we denote:

$$Z = (Y - \mathrm{E}(Y))^2 \tag{5.6.160}$$

then the unconditional variance of Y is obviously defined as:

$$\mathrm{V}(Y)=\mathrm{E}(Z) \tag{5.6.161}$$

Now let us now consider two random variables X, Y and we want to calculate the conditional variance of Y given X that we will denote $\mathrm{V}(Y|X)$. Similarly as the unconditional variance we can put:

$$Z=(Y-\mathrm{E}(Y|X))^2 \tag{5.6.162}$$

The conditional variance will be defined as:

$$\mathrm{V}(Y|X)=\mathrm{E}(Z|X) \tag{5.6.163}$$

Keep in mind that the unconditional variance is a scalar, when the conditional variance remains a random variable itself! So to get a scalar for the conditional variance, we have to estimate that latter for a given value of x, what we will denote by $\mathrm{V}(Y|X=x)$.

Thus:

$$\begin{aligned}\mathrm{V}(Y|X=x)&=\mathrm{E}\left((Y-\mathrm{E}(Y|X=x))^2|X\right)=\mathrm{E}\left(Y^2-2Y\mathrm{E}(Y|X=x)+(\mathrm{E}(Y|X=x)^2)|X\right)\\&=\mathrm{E}\left(Y^2|X=x\right)-2\mathrm{E}\left(Y\mathrm{E}(Y|X=x)|X=x\right)+\mathrm{E}\left(\mathrm{E}(Y|X=x)^2|X=x\right)\end{aligned} \tag{5.6.164}$$

As the terms $\mathrm{E}(Y|X=x)$ are scalars, we can take them out:

$$\begin{aligned}\mathrm{V}(Y|X=x)&=\mathrm{E}\left(Y^2|X=x\right)-2\mathrm{E}(Y|X=x)\mathrm{E}\left(Y|X=x\right)+\mathrm{E}(Y|X=x)^2\mathrm{E}\left(1|X=x\right)\\&=\mathrm{E}\left(Y^2|X=x\right)-2\left(\mathrm{E}(Y|X=x)\right)^2+\mathrm{E}(Y|X=x)^2\mathrm{E}\left(1|X=x\right)\end{aligned} \tag{5.6.165}$$

The expected conditional value of a constant is always equal to that constant, i.e.:

$$\mathrm{E}(1|X=x)=1 \tag{5.6.166}$$

Therefore:

$$\begin{aligned}\mathrm{V}(Y|X=x)&=\mathrm{E}\left(Y^2|X=x\right)-2\left(\mathrm{E}(Y|X=x)\right)^2+\mathrm{E}(Y|X=x)^2\\&=\mathrm{E}\left(Y^2|X=x\right)-\left(\mathrm{E}(Y|X=x)\right)^2\end{aligned} \tag{5.6.167}$$

We recognize in the last equality above, the Huygens relation (see page 593) of the unconditional mean. Therefore the conditional variance is defined as:

$$\boxed{\mathrm{V}(Y|X=x)=\mathrm{E}\left(Y^2|X=x\right)-\left(\mathrm{E}(Y|X=x)\right)^2} \tag{5.6.168}$$

Explicitly this will be written for continuous variables:

$$\mathrm{V}(Y|X=x)=\int\limits_y y^2f_{y|x}(y|x)\mathrm{d}y-\left(\int\limits_y yf_{y|x}(y|x)\mathrm{d}y\right)^2 \tag{5.6.169}$$

Theorem 5.39. Now let us prove the law of "iterated conditional variance", also named the "law of total variance":

$$\boxed{\mathrm{V}(Y)=\mathrm{E}(\mathrm{V}(Y|X=x))+\mathrm{V}(\mathrm{E}(Y|X=x))} \tag{5.6.170}$$

Proof 5.39.1. First we start form Huygens relation (see page 593):

$$\mathrm{V}(Y)=\mathrm{E}(Y^2)-\mathrm{E}(Y)^2 \tag{5.6.171}$$

The law of iterated means give us:

$$\mathrm{E}(Y^2)=\mathrm{E}\left(\mathrm{E}(Y^2|X=x)\right) \tag{5.6.172}$$

Injecting it in the previous relation, we get:

$$\mathrm{V}(Y)=\mathrm{E}\left(\mathrm{E}(Y^2|X=x)\right)-\mathrm{E}(Y)^2 \tag{5.6.173}$$

Using the result we have get earlier above:

$$\mathrm{V}(Y|X=x)=\mathrm{E}\left(Y^2|X=x\right)-(\mathrm{E}(Y|X=x))^2 \Leftrightarrow \mathrm{E}\left(Y^2|X=x\right)=\mathrm{V}(Y|X=x)+(\mathrm{E}(Y|X=x))^2 \tag{5.6.174}$$

and injecting that in the previous relation, we get:

$$\begin{aligned}\mathrm{V}(Y)&=\mathrm{E}\left[\mathrm{V}(Y|X=x)+(\mathrm{E}(Y|X=x))^2\right]-\mathrm{E}(Y)^2\\&=\mathrm{E}\left(\mathrm{V}(Y|X=x)\right)+\mathrm{E}\left((\mathrm{E}(Y|X=x))^2\right)-\mathrm{E}(Y)^2\end{aligned} \tag{5.6.175}$$

Now we use again the law of iterated means that we square:

$$(\mathrm{E}(Y))^2=(\mathrm{E}(\mathrm{E}(Y|X=x)))^2 \tag{5.6.176}$$

And we inject it in the previous relation to get:

$$\mathrm{V}(Y)=\mathrm{E}\left(\mathrm{V}(Y|X=x)\right)+\mathrm{E}\left((\mathrm{E}(Y|X=x))^2\right)-(\mathrm{E}(\mathrm{E}(Y|X=x)))^2 \tag{5.6.177}$$

We recognize in that latter equality the Huygens relation (see page 593)! Indeed:

$$\mathrm{V}(Y)=\mathrm{E}\left(\mathrm{V}(Y|X=x)\right)+\underbrace{\mathrm{E}\left((\mathrm{E}(Y|X=x))^2\right)-(\mathrm{E}(\mathrm{E}(Y|X=x)))^2}_{\mathrm{V}(\mathrm{E}(Y|X=x))} \tag{5.6.178}$$

So finally:

$$\mathrm{V}(Y)=\mathrm{E}(\mathrm{V}(Y|X=x))+\mathrm{V}(\mathrm{E}(Y|X=x)) \tag{5.6.179}$$

■ Q.E.D.

5.6.3.2 Bayesian Networks

"Bayesian networks", also named "Bayesian Belief Nets" abbreviated BNNs, or "Causal Bayesian networks, are simply a graphical representation of a problem of conditional probabilities to better visualize the interaction between the different variables when they begin to be in large numbers.

This is a technique increasingly used in decision aided software (Data Mining), artificial intelligence (A.I.) and also in the analysis and risk management (ISO 31010 norm).

Bayesian networks are by definition directed acyclic graphs (see section Graphs Theory page 3017), so that an event can not (even indirectly) influence its own probability, with quantitative description of dependencies between events.

These graphs are used for both knowledge representation models and calculating conditional probabilities machines. They are mainly used for diagnosis (medical and industrial), risk analysis (diagnostics failures, faults or accidents), spam detection (Bayesian filter), voice text and image opinions analysis, fraud detection or bad payers as well as data mining (M.K.M.: Mining and Knowledge Management) in general.

Remark

Many systems and software based on drawings or on information in existing databases exists to build and analyse Bayesian networks. Paid solutions: SQL Server, Oracle, Hugin. Free solutions (at this date): Tanagra, Microsoft Belief Network MSBNX 1.4.2, RapidMiner, `R` (`bnlearn` package). Personally for pedagogical reasons, I prefer the simplicity of the small software MSBNX from Microsoft. For information, in 15 years of professional experience as a consultant I have met so far only one company on more than 800 multinationals which used Bayesian networks... (in the field of transportation).

Use a Bayesian network is assimilated to do "Bayesian inference" or "Causal inference". Based on observed information (causal probabilities), we calculate the probability of possible known data but not observed.

For a given domain (e.g. medical), we describe the causal relations between variables of interest by a graph (we do not need again to specify that it is acyclic). In this graph, the causal relations between variables are not deterministic, but probabilistic. Thus, the observation of a cause or multiple causes does not always implies the effect or effects that depend on it, but only changes the probability of observing them.

The particular interest of Bayesian networks is to consider simultaneously a priori knowledge of experts (in the graph) and experience contained in the data.

Example of five variables with their relations (directed acyclic graph) and numbering of states/variables:

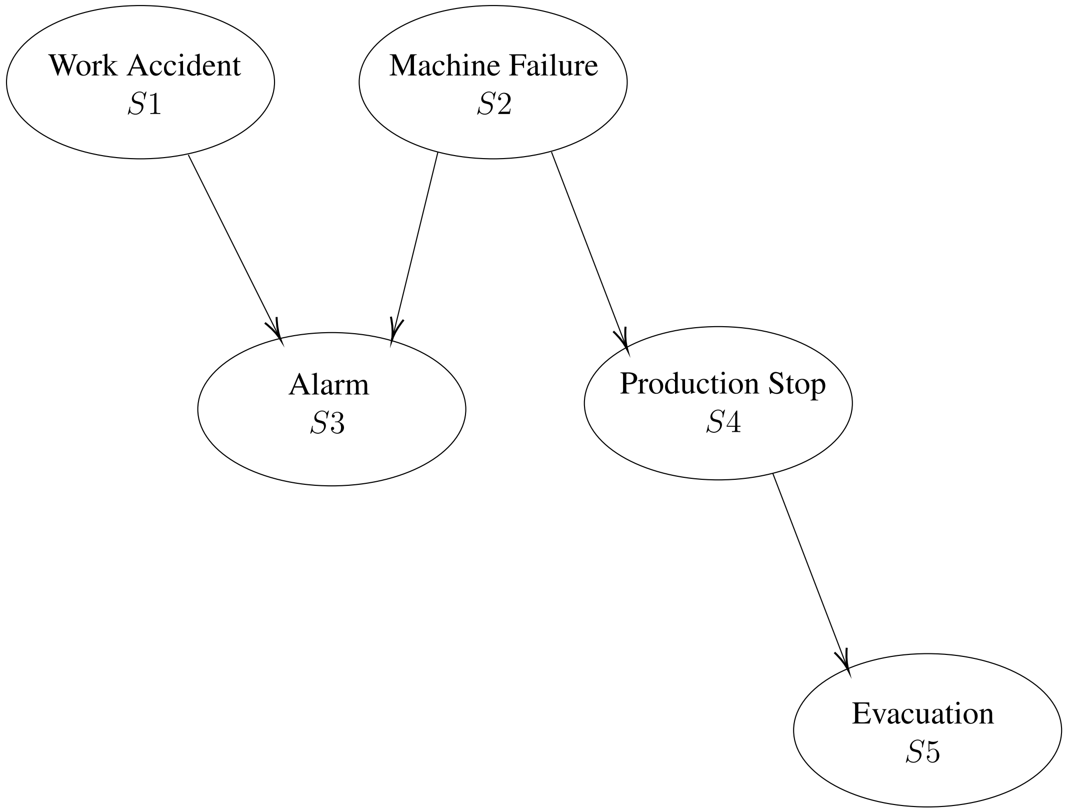


Figure 5.85: **Example of Bayesian network (acyclic oriented) with 5 states**

Obviously, the construction of the causal graph is based primarily on return of experience (REX) and sometimes results on standards or reports of expert committees. In computing science, the causal graph automatically change depending on the content of databases (think at the Amazon book store in real time target advertisements based on your past purchases or at the Genius Apple service). But we can rarely think to all possibilities and there will sometimes hidden states between two known states that have been forgotten and that would have allowed to better modelize the situations.

Suppose in the example above that with the help of a corporate database, we know that in about $100,000$ man-days, we had in the company $1,000$ accidents (i.e.. 1% of total) and 100 machines failures (i.e.. $0.01\%$of total). Then we represent it in the traditional form as follows:

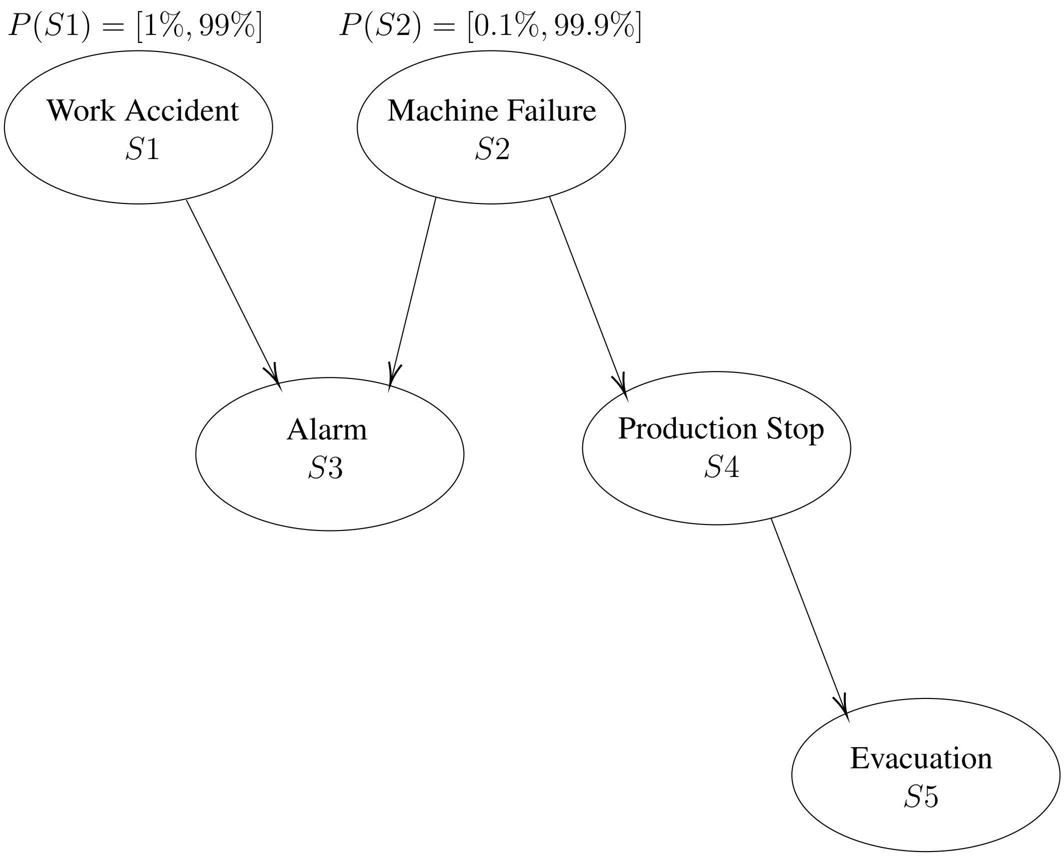

Figure 5.86: **Directed acyclic Bayesian network with probability of departure**

where we have the subset $S2, S4, S5$ which is what experts name a "serial or linear connection", the triplet $S3, S2, S4$ is a named a "divergent relation" (if the arrows were reversed for the triplet, we would have a "converging relation").

Before going further with our example we will make some observations in relation to these three types of relations:

For clarity, we distinguish first "conditional independence" and "conditional dependence".

We say that events A and C are "conditionally independent" if given an event B the following equality holds:

$$P(A/B) = P(A/B, C) \tag{5.6.180}$$

So the term "conditional" implies the presence of B and the fact that C does not influence the probability of the event A.

About "conditional dependence", this time we can distinguish three types of relations.

1. The conditional dependence of the following type is named a "serial or linear connection" (already mentioned above):

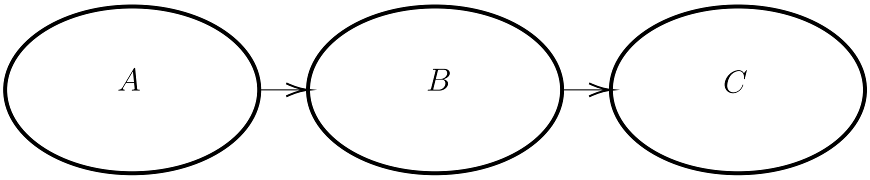

Figure 5.87: **Serial/linear Bayesian network**

where A, B and C are dependent (in this particular example there are 3 dependent nodes A, B and C, but in general this dependence relates to all nodes if there were more than 3)

In addition, A and C are conditionally dependent to B. But if the variable B is known, A no longer provides any useful information about C (the path of uncertainty is somehow broken) and therefore A and C become conditionally independent. We then have the conditional probability that simplify as follows:

$$P(C/B,A)=P(C/B) \tag{5.6.181}$$

2. The conditional dependence of the following type is named a "divergent connection" (as already mentioned above):

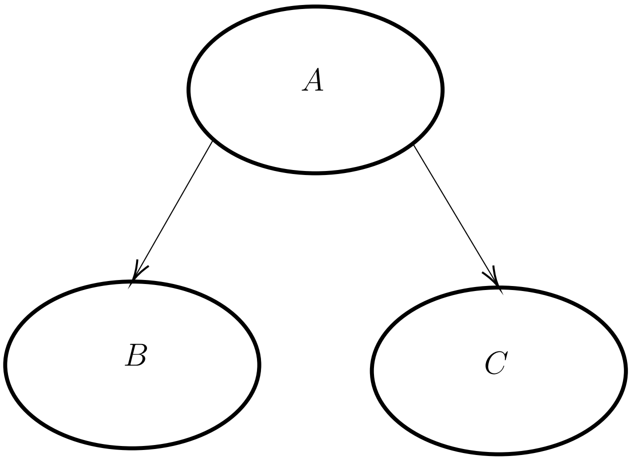

Figure 5.88: **Divergent Bayesian network**

In addition, B and C are conditionally dependent on A. But if A is known, B does not provide any more information on C (again the path of uncertainty is somehow broken) and therefore B and C become independent. We then have for example if A is known:

$$P(C/A,B)=P(C/A) \tag{5.6.182}$$

3. The conditional dependence of the following type is named a "convergence connection" or "V-Structure" (as already mentioned above):

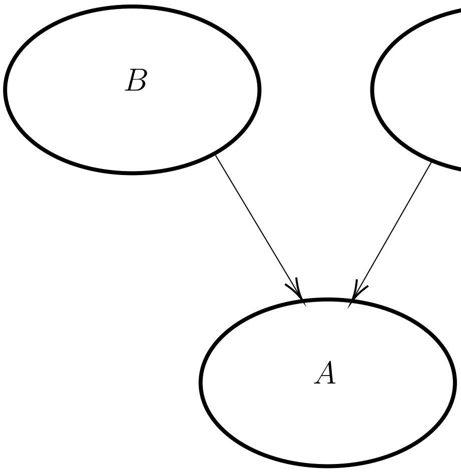

Figure 5.89: **Convergent Bayesian network**

where this time the parents are independent.

So B and C are independent but become conditionally dependent on A. If A is known, then we have:

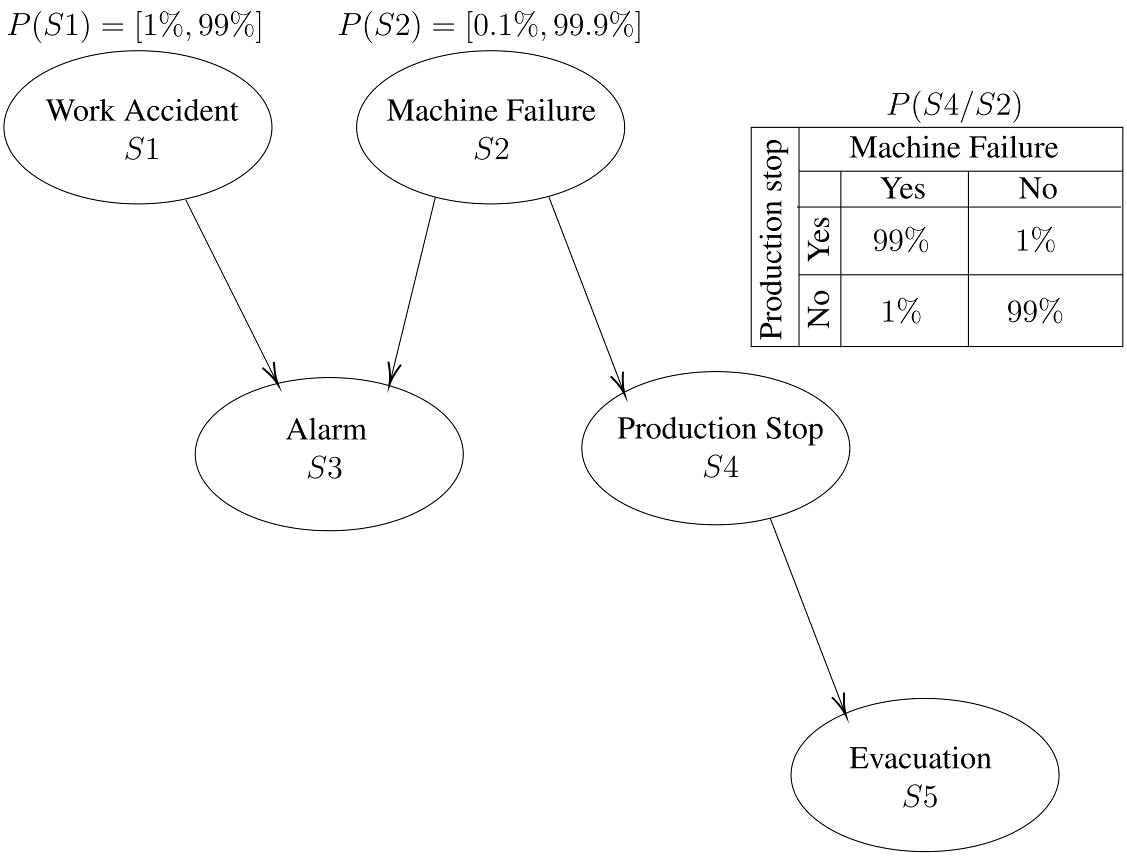
$$P(A/B,C)=P(A/B) \tag{5.6.183}$$

The dependence between parents therefore requires the observation of their common child.

Now to make a concrete example, let us first recall the Bayes' theorem:

$$\underbrace{P(A/B)}_{\text{posterior probability}}=\frac{\overbrace{P(B/A)}^{\text{Likelihood}}\cdot\overbrace{P(A)}^{\text{priori probability}}}{\underbrace{P(B)}_{\text{expectedness}}} \tag{5.6.184}$$

and now suppose that we have a knowledge database that gives us (thanks to quality managers who always inputs the quality issues) that when a machine failure occurred, 99 times out of 100 (99%) there has been a total production stop (i.e. 1% of time there was no production stop) and on all stop production 1% was not due to a machine failure. What we traditionally represent as follows:



$P(S1) = [1\%, 99\%]$
$P(S2) = [0.1\%, 99.9\%]$
Work Accident $S1$
Machine Failure $S2$
Alarm $S3$
Production Stop $S4$
Evacuation $S5$

$P(S4/S2)$

		Machine Failure	
		Yes	No
Production stop	Yes	99%	1%
	No	1%	99%

Figure 5.90: Directed acyclic Bayesian network with probability of departure

So the "implicit probability" (expectedness) that there is a production stop is given by:

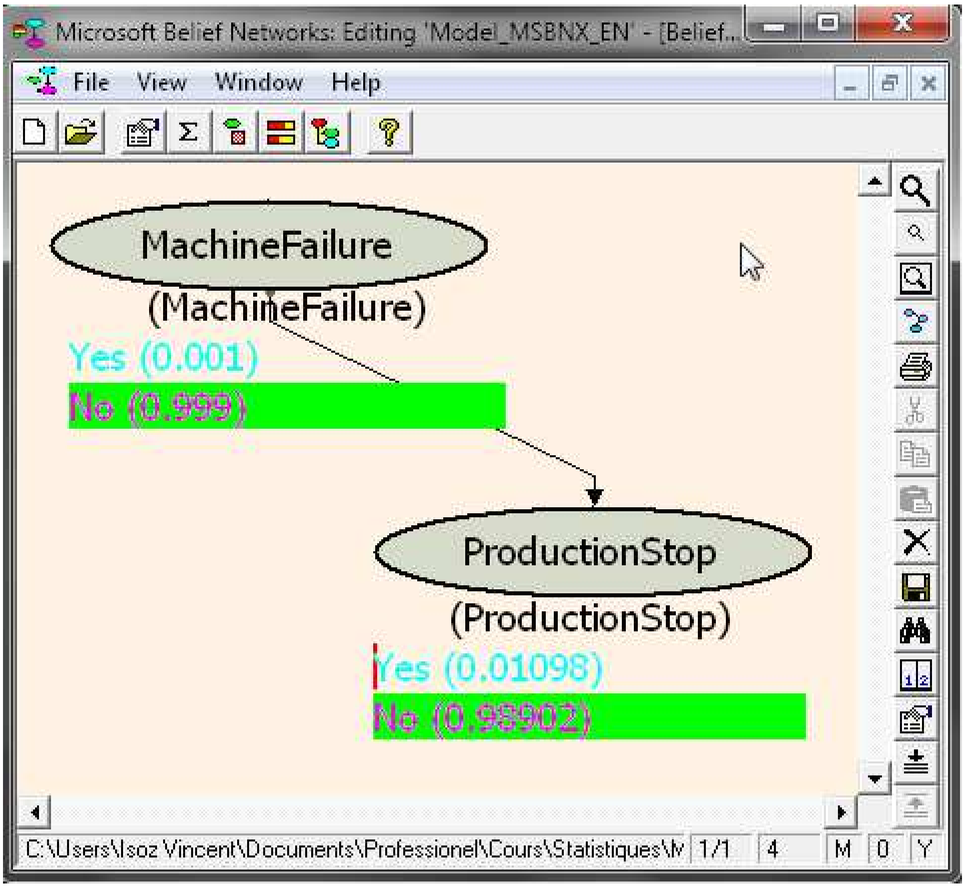
$$P(S4) = P(S4/S2)P(S2) + P(S4/\overline{S2})P(\overline{S2}) = 99\% \cdot 0.1\% + 1\% \cdot 99.9\% \cong 1.098\% \quad (5.6.185)$$

This value represents the implicit proportion of productions stop from the $100,000$ man-days (so we can give a proportion of rows in the database that represents a production stop regardless of the cause and even without knowing the details of the database).

It then follows immediately that the implicit probability (expectedness) that there is no production stop is given by:

$$P(S4) = 1 - P(\overline{S4}) \cong 98.902\% \quad (5.6.186)$$

This is consistent with what gives us the freeware MSBNX 1.4.2:



Microsoft Belief Networks: Editing 'Model_MSBNX_EN' - [Belief...
File View Window Help

C:\Users\Isoz Vincent\Documents\Professionel\Cours\Statistiques\M 1/1 4 M 0 Y

Figure 5.91: **Beginning of the Bayesian network with MSBNX 1.4.2**

Now suppose we observed a production stop. What is the a posteriori probability that it is due to a machine failure? We then have:

$$P(S2/S4)=\frac{P(S4/S2)P(S2)}{P(S4)}=\frac{99\%\cdot 0.1\%}{1.098\%}\cong 9.02\% \tag{5.6.187}$$

We can also check this with the software MSBNX 1.4.2:

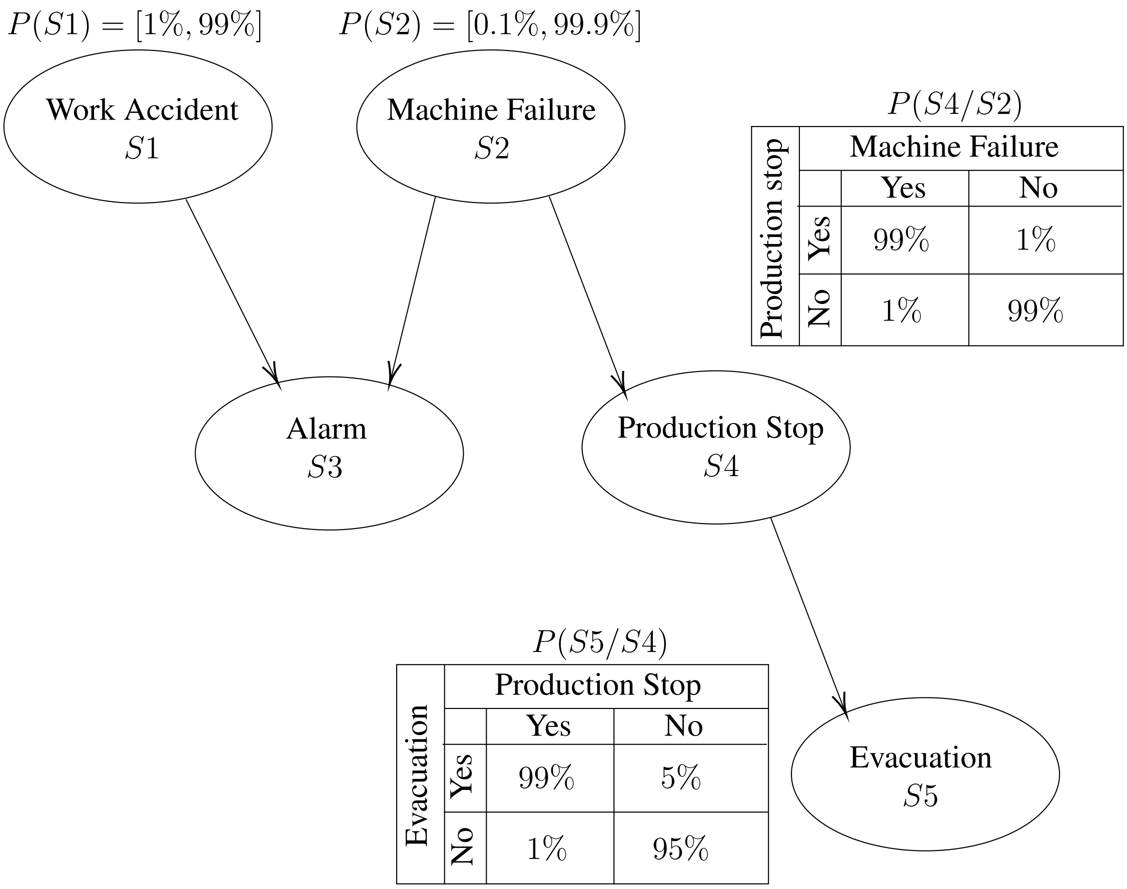
Node Name	State 0	State 1
Machine Failure	Yes	No
	0.0902	0.9098
Production Stop	Yes	No
	1.0000	0.0000

Figure 5.92: **A Posteriori probability of a production stop due to a machine failure in MSBNX 1.4.2**

Now, imagine that our database gives us (always thanks to quality managers who ensured to input quality issues) that 99 times out of 100 (99%) when there was a production stop, there was an evacuation. However 5% of evacuations were identified as having nothing to do with a production stop (i.e. 95% of evacuations are due to fire exercises OR other events):



$P(S4/S2)$

Production stop	Machine Failure: Yes	Machine Failure: No
Yes	99%	1%
No	1%	99%

$P(S5/S4)$

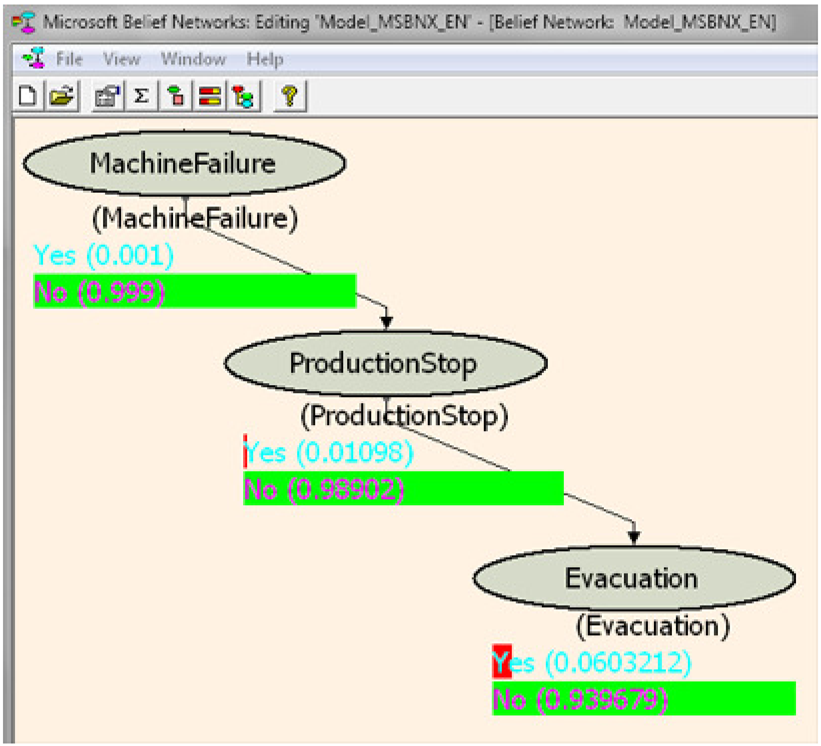
Evacuation	Production Stop: Yes	Production Stop: No
Yes	99%	5%
No	1%	95%

Figure 5.93: **2nd level Bayesian network**

Now to calculate the implicit probability (expectedness) of evacuations compared to machines failures, we saw that when we had a conditional dependence series, the conditional probability depends only on the direct parent. Thus, we get the following expectedness:

$$P(S5)=P(S5/S4)P(S4)+P(S5/\overline{S4})P(\overline{S4})=99\%\cdot 1.089\%+5\%\cdot 98.092\%\cong 6.03\% \tag{5.6.188}$$

We can also check that this result is compliant with the on given by the software MSBNX 1.4.2:



Microsoft Belief Networks: Editing 'Model_MSBNX_EN' - [Belief Network: Model_MSBNX_EN]
File View Window Help
MachineFailure
(MachineFailure)
Yes (0.001)

Evacuation
(Evacuation)
Yes (0.0603212)
No (0.939679)

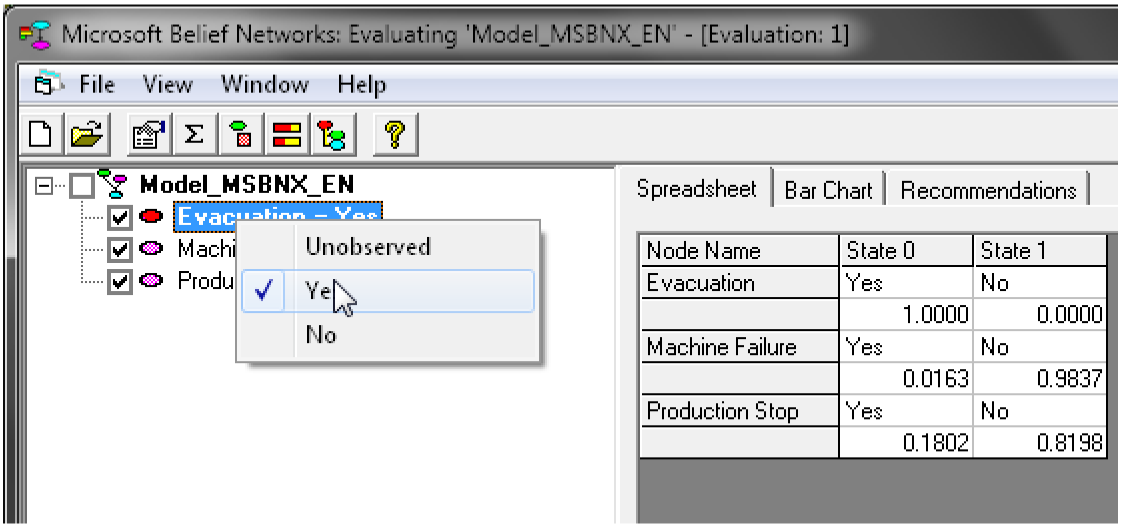
Figure 5.94: Implicit probability of an evacuation in MSBNX 1.4.2

So the implicit probability (expectedness) of evacuation does not actually depend on machine failures.

Now suppose we have observed an evacuation. We want to know what is the a posteriori probability that it is due to a machine failure! Then we have:

$$P(S4/S5)=\frac{P(S5/S4)P(S4)}{P(S5)}=\frac{99\%\cdot 1.098\%}{6.03\%}\cong 18.02\% \qquad (5.6.189)$$

We can also check this with the software MSBNX 1.4.2:



Microsoft Belief Networks: Evaluating 'Model_MSBNX_EN' - [Evaluation: 1]
File View Window Help
Model_MSBNX_EN
Evacuation = Yes

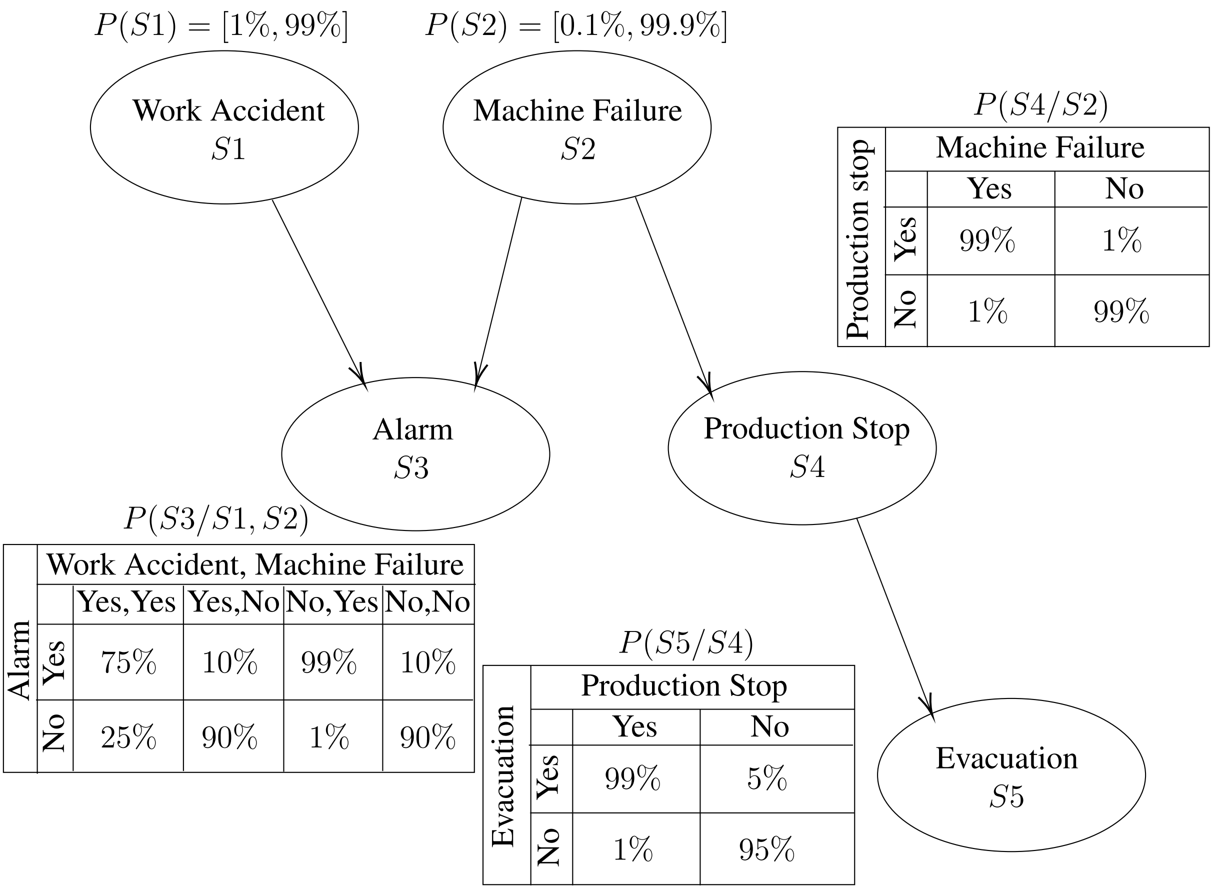
Production Stop	Yes	No
	0.1802	0.8198

Figure 5.95: A Posteriori probability of an evacuation due to a machine failure in MSBNX 1.4.2

Now we study the case with the alarm and again a database allows us to build a table with different probabilities:



$P(S4/S2)$

		Machine Failure	
		Yes	No
Production stop	Yes	99%	1%
	No	1%	99%

$P(S3/S1,S2)$

		Work Accident, Machine Failure			
		Yes,Yes	Yes,No	No,Yes	No,No
Alarm	Yes	75%	10%	99%	10%
	No	25%	90%	1%	90%

$P(S5/S4)$

		Production Stop	
		Yes	No
Evacuation	Yes	99%	5%
	No	1%	95%

Figure 5.96: **2nd level Bayesian network with second branch**

Now to calculate the implicit probability (expectedness) that there is an alarm, we will have to consider the four possible situations. We then use again the theorem of total probability:

$$\begin{aligned}P(S3)=&P(S3/S1,S2)P(S1)P(S2)+P(S3/\overline{S1},S2)P(\overline{S1})P(S2)\\&+P(S3/S1,\overline{S2})P(S1)P(\overline{S2})+P(S3/\overline{S1},\overline{S2})P(\overline{S1})P(\overline{S2})\end{aligned}\tag{5.6.190}$$

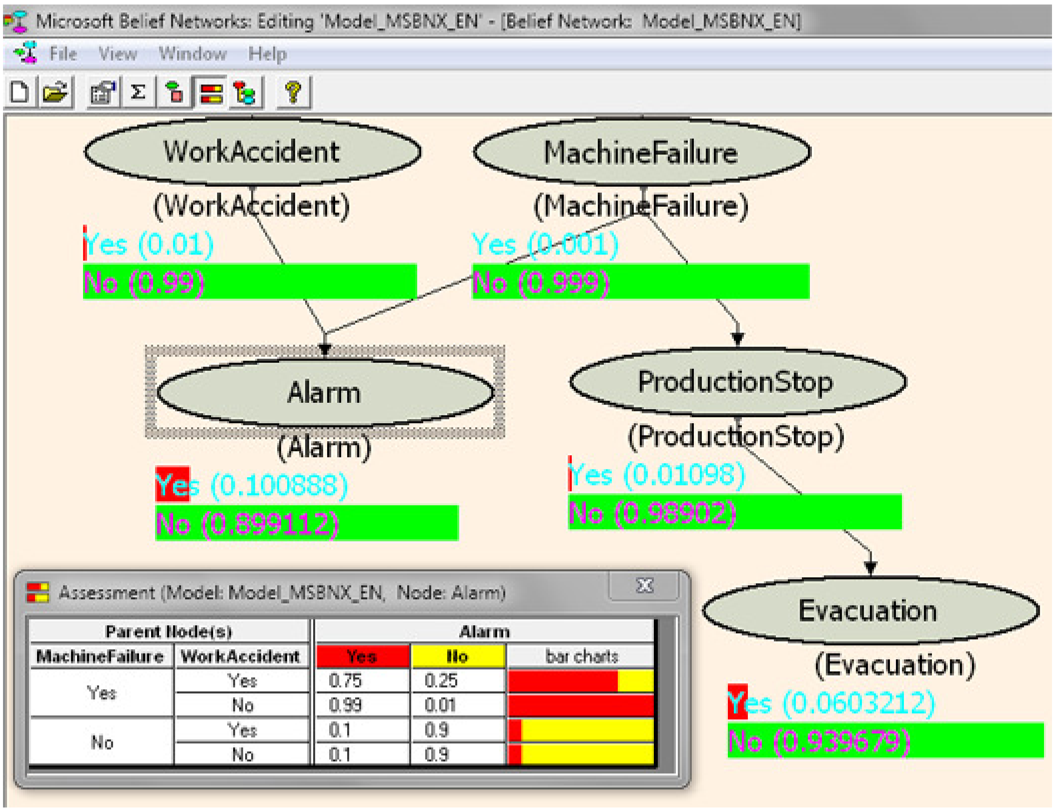
What a little more rigorously should be written:

$$\begin{aligned}P(S3)=&P(S3/S1\wedge S2)P(S1)P(S2)+P(S3/\overline{S1}\wedge S2)P(\overline{S1})P(S2)\\&+P(S3/S1\wedge\overline{S2})P(S1)P(\overline{S2})+P(S3/\overline{S1}\wedge\overline{S2})P(\overline{S1})P(\overline{S2})\end{aligned}\tag{5.6.191}$$

The numerical application therefore provides for the implied probability (expectedness) of an alarm:

$$\begin{aligned}P(S3)=&75\%\cdot 1\%\cdot 0.1\%+99\%\cdot 99\%\cdot 0.1\%+10\%\cdot 1\%\cdot 99.9\%\\&+10\%\cdot 99\%\cdot 99.9\%\cong 10.089\%\end{aligned}\tag{5.6.192}$$

What can be built and check as follows with MSBNX 1.4.2:



Microsoft Belief Networks: Editing 'Model_MSBNX_EN' - [Belief Network: Model_MSBNX_EN]

No	Yes	0.1	0.9	
	No	0.1	0.9	

Figure 5.97: **Implicit probability in MSBNX 1.4.2**

It may be useful to the reader to know that he can sometimes found in the literature the following notations:

$$P(S3/S1=\text{Yes},S2=\text{Yes})=P(S3/S1,S2)=P(S3/S1\wedge S2) \tag{5.6.193}$$

or:

$$P(S3|S1=\text{Yes},S2=\text{Yes})=P(S3|S1,S2)=P(S3|S1\wedge S2) \tag{5.6.194}$$

Remark

In the particular example studied above all event have only two states. But in practice they can have 3, 4 and more states. Therefore probabilities cross-tables quickly become enormous.

As in the previous case, suppose we know that there was a working accident. We wish then calculate the a posteriori probability of an alarm. We then have (observe that the probability depends actually only to the state $S2$ state since the state $S1$ is completely known!):

$$\begin{aligned}P(S3/S1)&=P(S3/S1,S2)P(S2)+P(S3/S1,\overline{S2})P(\overline{S2})\\&=75\%\cdot 0.1\%+10\%\cdot 99.9\%=10.065\%\end{aligned} \tag{5.6.195}$$

We can also check this with the software MSBNX 1.4.2:

Figure 5.98: **Implicit probability of an alarm in MSBNX 1.4.2**

To complete this example, we would calculate the a posteriori probabilities $P(S2/S3)$ and $P(S1/S3)$. To do this, we must first calculate the a priori probabilities $P(S3/S2)$ and $P(S3/S1)$ (this last one has been calculated just before).

We have for the missing value (which can be easily checked as before with MSBNX 1.4.2 software):

$$\begin{aligned} P(S3/S2) &= P(S3/S2,S1)P(S1) + P(S3/S2,\overline{S1})P(\overline{S1}) \\ &= 75\% \cdot 1\% + 99\% \cdot 99\% \cong 98.76\% \end{aligned} \tag{5.6.196}$$

We then have:

$$\begin{aligned} P(S3/S1) &= 10.065\% \\ P(S3/S2) &= 98.76\% \end{aligned} \tag{5.6.197}$$

We now have everything we need to calculate the a posteriori probability of $P(S2/S3)$ and $P(S1/S3)$:

$$\begin{aligned} P(S2/S3) &= \frac{P(S3/S2)P(S2)}{P(S3)} = \frac{98.76\% \cdot 0.1\%}{10.089\%} = 0.9789\% \\ P(S1/S3) &= \frac{P(S3/S1)P(S1)}{P(S3)} = \frac{10.065\% \cdot 1\%}{10.089\%} = 0.9976\% \end{aligned} \tag{5.6.198}$$

So the a posteriori probability that there is a machine breakdown when we know that there is an alarm is 0.979% (i.e. 0.021% that the trigger of the alarm is not a priori due to a machine failure). Respectively there is, a posteriori, 0.998% probability that there is a work accident when we know there is an alarm (and then 0.002% that it is not a priori due to a work accident).

From the critical point of view, when there is finally an alarm we can not say a lot of things.... This is because, in this case, to the fact that the events of significant interest both have low probability to occur (work accident and machine failure) and that the employees respond quite well at the start of the alarm (otherwise if the a priori probabilities were high it would mean that the behaviour of the employees is not good because we can guess - with exasperation - in advance which problem occurs with a good confidence).

Remark

We did not find how to check these last calculations with MSBNX 1.4.2. If someone finds how to do, it would be great to give us the details of the process.

To conclude, the reader will have noticed that the calculations can quickly become annoying when the graph becomes complex and this explains the use of computer software. Furthermore, in the banking sector that uses for example Bayesian networks for credit risk, the a priori probability can be more complex. For example we might want to know the a priori probability that there is a machine failure knowing that we have an alarm and an accident:

$$P(S2/S3,S1)=P(S2/S3=\text{Yes},S1=\text{Yes}) \tag{5.6.199}$$

For people wishing to go deeper into the subject, with practical cases on `R` software and the use of Bayesian Gaussian networks, we strongly recommend reading [486]!

Remark

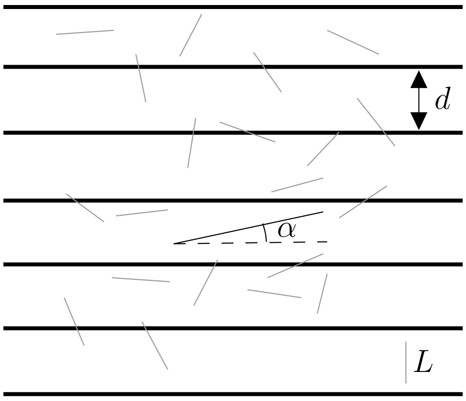
The Bayesian causal networks we have looked at so far do not show the passage of time. Yet time is essential to causality, insofar as effects must not precede their causes. Fortunately, it is easy to incorporate time into BNs by using successive time periods, named "time slices", to distinguish between the values of the same variables at different times or in different time periods. This creates a "dynamic Bayesian network" (DBN) that shows dependencies among the values of different random variables over time.

5.6.4 Geometric Probabilities

In mathematics, Buffon's needle problem is a question first posed in the 118th century (holocene calendar) by Georges-Louis Leclerc, Comte de Buffon. Buffon's needle is very interesting because it is known as the earliest problem in "geometric probability" to be solved using integral geometry. Furthermore there are many similar cases of calculations in particle physics and astrophysics.

The problem is stated as following: Suppose that you drop a short needle on ruled paper what is then the probability that the needle comes to lie in a position where it crosses one of the lines?

The probability depends on the distance d between the lines of the ruled paper, and it depends on the length L of the needle that we drop - or rather it depends only on the ratio L/d. A short needle for our purpose is one of length $L\leq d$. In other words, a short needle is one that cannot cross two lines at the same time (and will come to touch two lines only with probability zero).



The trick to get a solution is to consider the slope of the needle; let's say it drops to lie with an angle of α away from horizontal, where α will be in the range $0 \leq \alpha \leq \frac{\pi}{2}$ (we will ignore the case where the needle comes to lie with negative slope, since that case is symmetric to the case of positive slope, and produces the same probability). A needle that lies with angle α has height $L\sin(\alpha)$, and the probability that such a needle crosses one of the horizontal lines of distance d is:

$$\frac{L\sin(\alpha)}{d} \tag{5.6.200}$$

Thus we get the probability by averaging over the possible angles α, as:

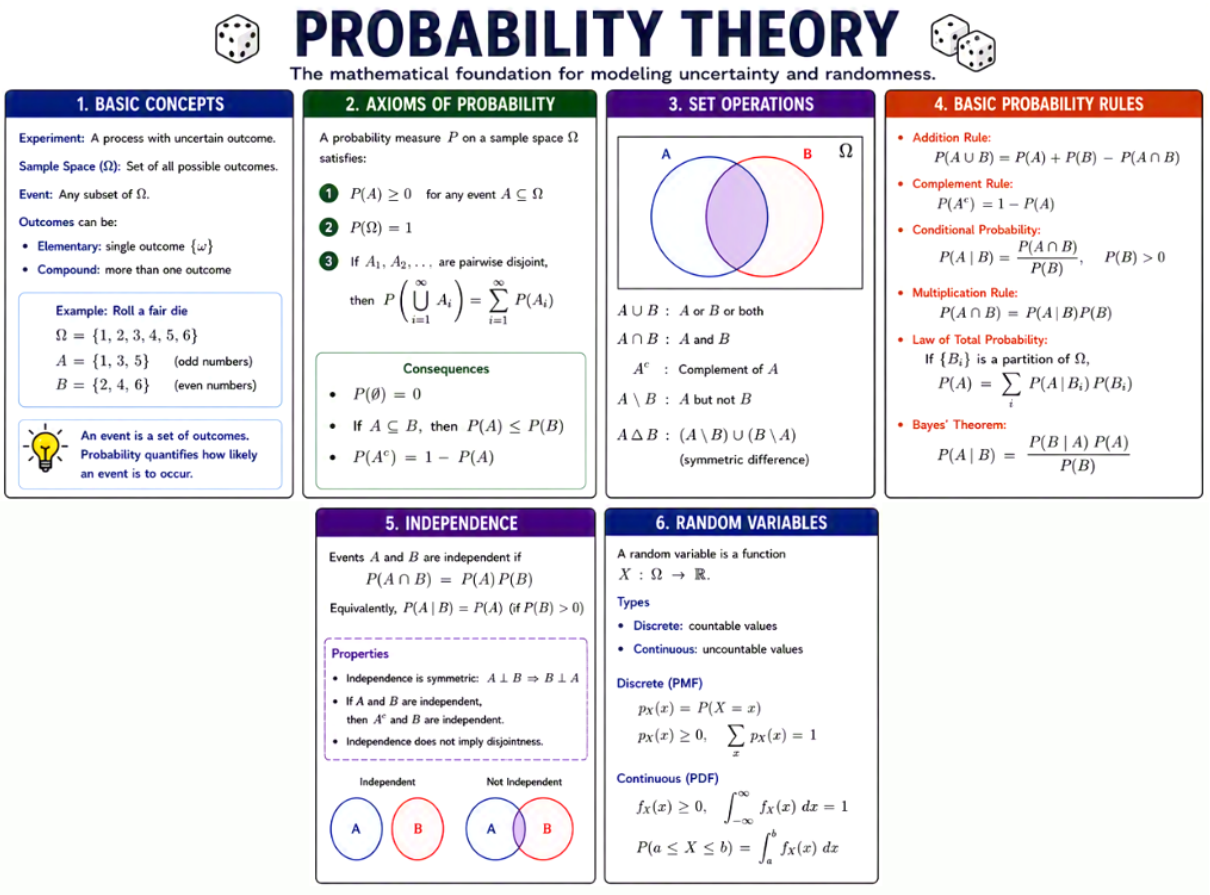
$$P = \frac{1}{\pi/2}\int\limits_0^{\pi/2}\frac{L\sin(\alpha)}{d}\mathrm{d}\alpha = \frac{2}{\pi}\frac{L}{d}\int\limits_0^{\pi/2}\sin(\alpha)\mathrm{d}\alpha = \frac{2}{\pi}\frac{L}{d}\left[-\cos(x)\right]_0^{\pi/2} = \frac{2}{\pi}\frac{L}{d} \tag{5.6.201}$$

For a long needle, we get the same probability $\frac{L\sin(\alpha)}{d}$ as long as $L\sin(\alpha) \leq d$ that is, in the range $0 \leq \alpha \leq \arcsin(d/L)$. However, for larger angles c the needle must cross a line, so the probability is 1. Hence we compute:

$$\begin{aligned} P &= \frac{2}{\pi}\left(\int\limits_0^{\arcsin(d/L)}\frac{L\sin(\alpha)}{d}\mathrm{d}\alpha + \int\limits_{\arcsin(d/L)}^{\pi/2} 1 d\mathrm{d}\alpha\right) \\ &= \frac{2}{\pi}\left[\frac{L}{d}[-\cos\alpha]_0^{\arcsin(d/L)} + \left(\frac{\pi}{2} - \arcsin\left(\frac{d}{L}\right)\right)\right] \\ &= 1 + \frac{2}{\pi}\left[\frac{L}{d}\left(1 - \sqrt{1 - \frac{d^2}{L^2}}\right) - \arcsin\left(\frac{d}{L}\right)\right] \end{aligned} \tag{5.6.202}$$

for $L \leq d$.

This last relation yields obviously $2/\pi$ for $L = d$. And it tends to 1 for $L \to +\infty$.



A
B

PROBABILITY THEORY

The mathematical foundation for modeling uncertainty and randomness.

1. BASIC CONCEPTS

Experiment: A process with uncertain outcome.

Sample Space (Ω): Set of all possible outcomes.

Event: Any subset of Ω.

Outcomes can be:

- **Elementary:** single outcome $\{\omega\}$
- **Compound:** more than one outcome

Example: Roll a fair die

$\Omega = \{1, 2, 3, 4, 5, 6\}$

$A = \{1, 3, 5\}$ (odd numbers)

$B = \{2, 4, 6\}$ (even numbers)

An event is a set of outcomes. Probability quantifies how likely an event is to occur.

2. AXIOMS OF PROBABILITY

A probability measure P on a sample space Ω satisfies:

① $P(A) \geq 0$ for any event $A \subseteq \Omega$

② $P(\Omega) = 1$

③ If $A_1, A_2, \ldots$ are pairwise disjoint, then $P\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} P(A_i)$

Consequences

- $P(\emptyset) = 0$
- If $A \subseteq B$, then $P(A) \leq P(B)$
- $P(A^c) = 1 - P(A)$

3. SET OPERATIONS

$A \cup B$: A or B or both

$A \cap B$: A and B

A^c : Complement of A

$A \setminus B$: A but not B

$A \Delta B$: $(A \setminus B) \cup (B \setminus A)$ (symmetric difference)

4. BASIC PROBABILITY RULES

- **Addition Rule:** $P(A \cup B) = P(A) + P(B) - P(A \cap B)$
- **Complement Rule:** $P(A^c) = 1 - P(A)$
- **Conditional Probability:** $P(A \mid B) = \dfrac{P(A \cap B)}{P(B)}, \quad P(B) > 0$
- **Multiplication Rule:** $P(A \cap B) = P(A \mid B)P(B)$
- **Law of Total Probability:** If $\{B_i\}$ is a partition of Ω, $P(A) = \sum_i P(A \mid B_i)\, P(B_i)$
- **Bayes' Theorem:** $P(A \mid B) = \dfrac{P(B \mid A)\, P(A)}{P(B)}$

5. INDEPENDENCE

Events A and B are independent if

$$P(A \cap B) = P(A)\, P(B)$$

Equivalently, $P(A \mid B) = P(A)$ (if $P(B) > 0$)

Properties

- Independence is symmetric: $A \perp B \Rightarrow B \perp A$
- If A and B are independent, then A^c and B are independent.
- Independence does not imply disjointness.

6. RANDOM VARIABLES

A random variable is a function $X : \Omega \rightarrow \mathbb{R}$.

Types

- **Discrete:** countable values
- **Continuous:** uncountable values

Discrete (PMF)

$$p_X(x) = P(X = x)$$

$$p_X(x) \geq 0, \quad \sum_x p_X(x) = 1$$

Continuous (PDF)

$$f_X(x) \geq 0, \quad \int_{-\infty}^{\infty} f_X(x)\, dx = 1$$

$$P(a \leq X \leq b) = \int_a^b f_X(x)\, dx$$

5.6.5 Martingales

A martingale in probabilities (there is another one in stochastic processes) is a technique to increase the chances of winning in gambling while respecting the rules of the game. The principle is completely dependent on the type of game we are focusing, but this term is accompanied by an aura of mystery that some players would know efficient secret techniques to cheat with chance. For example, many players (or candidates to play) search THE martingale that will beat the bank in the most common games in casinos (institutions whose profitability relies almost entirely on the difference - however small - between the chances of winning and losing as we will see in details further below).

Many martingales are the dream of their author, some are actually inapplicable, some could actually give the possibility to cheat a little. Gambling in general are unfair: whatever the shot played, the probability of winning of the casino (or of the State in the case of a lottery) is greater than this of the player. In this type of game, it is not possible to inverse the chances, just to minimize the probability of gambler's ruin.

The most common example is the roulette wheels martingale. It consists to play a single chance to the roulette wheels (red or black, odd or even) to win, for example, a unit in a series of moves by doubling his bet if we lose, and that until we earn. Example: the player bets 1 unit on red, if red comes out, it stops playing and won 1 unit (2 units less gain setting unit), if black comes out, he doubles his betting by 2 units on red and so on until he wins.

Figure 5.99: **Casino roulette wheel**

Having a chance on two to win, he may think he will eventually win, and when he wins, he is necessarily paid for everything he has played more one unit of his initial bet.

This martingale appears to be safe in practice. Note that in theory, to be sure of winning, we should have the opportunity to play an unlimited number of times.... This has major drawbacks:

This martingale is in fact limited by the bets that the player can do because you have to double the bet every time you lose: 2 times the initial bet, then 4, 8, 16 .... if he loses 10 times, he must be able to bet 1024 times its initial investment for the 11th party! Therefore a lot of money for little gain!

The roulette wheels also have a "0" which is neither red nor black. The risk of losing at every shot is then larger than $1/2$...

In addition, to paralyse this strategy, casinos offer table games per set: from 1 to 100.-, from 2 to 200.-, from 5 to 500.-, ... Therefore it is impossible to use this method on a large number of shots, which increases the risk of losing it all.

Blackjack is a game that has winning strategies: several playing techniques, which usually require to memorize the cards, can overturn the chances in favour of the player. The mathematician Edward Thorp has published in 11962 (holocene calendar) a book that was at the time a real best-seller. But all these methods require long training weeks and are easily detectable by the croupier (sudden changes in the amounts of bets are typical). The casino has then the opportunity to banish from its establishment the players using this playing martingale.

It should be noted that there are enough advanced methods. One of them is based on the less played combinations. In games where the gain depends on the number of winning players (Lotto...), playing the least played combinations maximize gains. This is how some people sell combinations that would be statistically very rarely used by other players.

Based on this reasoning, we can still conclude that a player who would have been able to determine statistically the least played combinations, to maximize its expected payoff, will in fact certainly not be the only player to have achieved this by the analysis of these famous combinations! This means that in theory the numbers the least played are actually overplayed combinations, the best might be to achieve a mix of played numbers and overplayed numbers to play for the ideal combinations. Another conclusion to all this is maybe that the best is to play random combinations which ultimately are less likely to be chosen by the players who incorporate a human and harmonious factor in the choice of their numbers.

5.6.5.1 Gambling

At its core the business of casino gaming is pretty simple. Casinos make money on their games because of the mathematics behind the games. As Nico Zographos, dealer-extraordinaire for the 'Greek Syndicate' in Deauville, Cannes, and Monte Carlo in the 11920s (holocene calendar) observed about casino gaming: «*There is no such thing as luck. It is all mathematics.*»

With a few notable exceptions, the house always wins in the long run[30] because of the mathematical advantage the casino enjoys over the player.

A common question about gampling is: How does house always win in gambling, even if the chances are $50/50$?

The answer relies in the fact that when a player lose the hand, they take his bet. If you win the hand, they only give you back your bet plus 95% of his bet. In order to calculate winnings we need to understand the concept of expected value.

In short, expected value is the expected payout from a particular probabilistic event. In simple case, we can calculate it by summing all the possible probabilities p_i multiplied by their payouts Pay-out$_i$. In this example if the player bets \$$1$ every game, he will gain \$$0.95$ when he wins and lost \$$1$ when he lose. Ignoring the possibility of a tie this comes out to!

The expected payout value is therefore:

$$\text{E(Pay-out)} = \sum_i p_i \text{Pay-out}_i = 0.5 \cdot (-1) + 0.5 \cdot (0.95) = -0.025 \qquad (5.6.203)$$

This means that on any given hand, the player will expect to lose about 2 or 3 cents. Really, he is actually gaining \$$0.95$ or losing \$$1$ but on average if he plays forever, it will come out to \$$-0.025$ per hand and he will slowly lose money. Even though the chances of winning any given hand are $50/50$.

In other words, by the law of large numbers (see further below page 920) says that as the number of bets placed goes to infinity, the average profit or loss realized by a player per bet will converge to the expected value. Since the expected value is negative, that means that the infinitely busy gambler will lose infinitely much money (or more realistically, go bankrupt). Or from the another point of view, the house always wins because the casino makes a LARGE number of bets.

---

[30] Without this underlined term, the sentence makes no sense. The devil is in the details!

The house advantage - the all-important percentage that explains how casinos make money - is also named the "house edge", the "theoretical win percentage", and "expected win percentage". In double-zero roulette, this figure is 5.3%. In the long run the house will retain 5.3% of the money wagered. In the short term, of course, the actual win percentage will differ from the theoretical win percentage (the magnitude of this deviation can be predicted from statistical theory). The actual win percentage is just the (actual) win divided by the handle. Because of the law of large numbers - or as some prefer to name it, the "law of averages" - as the number of trials gets larger, the actual win percentage should get closer to the theoretical win percentage.

Remark

In an effort to entice players and increase business, casinos occasionally offer novel wagers, side bets, increased payoffs, or rule variations. These promotions have the effect of lowering the house advantage and the effective price of the game for the player. This is sound reasoning from a marketing standpoint, but can be disastrous for the casino if care is not taken to ensure the math behind the promotion is sound (the are some famous examples of such disasters with a Illinois riverboat Casino, also an Indian Casino in California and some Casinos in Las Vegas, etc.).

The two tables below show the house advantages for many of the popular casino games:

Popular Casino Games (under optimal strategies)	**House Advantage**
Roulette (double-zero)	5.3%
Craps (pass/come)	1.4%
Craps (pass/come with double odds)	0.6%
Blackjack - average player	2.0%
Blackjack - 6 decks, basic strategy	0.5%
Blackjack - single deck, basic strategy	0.0%
Baccarat (no tie bets)	1.2%
Caribbean Stud	5.2%
Let It Ride	3.5%
Three Card Poker	3.4%
Pai Gow Poker (ante/play)	2.5%
Slots	$5-10\%$
Video Poker	$0.5-3\%$
Keno (average)	27%

Let us prove for example where the value 5.3% for the Roulette above comes from!

The house edge is the percentage of each bet that the casino expects to win over the long run. The easiest way to calculate this number is to assume that someone is playing for \$100 a bet, and determining how much he'll lose on average over the long run, then divide that into the number of bets.

I'll use roulette as an example again, because it's illustrative.

You place 38 bets on a single number at the roulette table. If you had a mathematically perfect set of spins (which is what you want to assume when you're calculating the house edge), you'll win once and lose 37 times.

The winning bet pays off at 35 to 1, so you'll win \$$3500$ on it. But you'll lose \$$3700$ on the 37 losing spins. Your net loss is \$$3700-$ \$$3500$, or \$$200$.

If you divide \$$200$ by 38, you get \$$5.26$ per spin, which is your average loss per spin.

That is the house edge for the game -5.26%.

Caution!!!!!!!!! It's important to remember that the house edge is a long term mathematical expectation. In the short term, anything can (and often will) happen.

We will stop here about the subject of gambling because it's not the most ethical business and there are already plenty of graduate level textbooks dedicated to that topic.

5.6.6 Combinatorial Analysis

"Combinatorial analysis" (counting techniques) is the field of mathematics that deals with the study of all the issues, events or facts (distinguishable or indistinguishable) with their arrangements (combinations) ordered or not according to some given constraints.

Definitions (#5.6.107):

D1. A sequence of objects (events, issues, objects, ...) is said "ordered" if each suite with a particular order of objects is recognized as a particular configuration.

D2. A sequel is "unordered" if and only if we are interested in the frequency of appearance of objects regardless of their order.

D3. The objects (of a sequence) are said "distincts" if their characteristics can not to be confused with the other objects.

Remark

We chose to put combinatorial analysis in this chapter because when we calculate probabilities, we also often need to know what is the probability of finding a combination or arrangement of given events under given constraints. Also we have decided (as always!) to focus on combinatorial mathematics that have important practical applications in others sections of this textbook!

Students often have difficulty remembering the difference between a permutation, an arrangement and a combination. Here is a little summary of what we'll see:

- Permutation: We take all the objects.
- Arrangement: We choose objects from the original set and the order intervenes.
- Combination: Same as for the arrangement, but the order does not intervenes.

You must not forget that for each result, the reverse will give the probability of falling respectively on a given permutation/arrangement/combination!

We will present and demonstrate below the 6 most common cases from which we can find (usually) all others:

5.6.6.1 Simple Arrangements with Repetitions

Definition (#5.6.108): A "simple arrangement with repetition" or equivalently a "random sampling with replacement"" (RSWR) is an ordered sequence of length m of n distinct objects not necessarily all different in the sequence (either: with possible repetitions!).

Let A and B be two finite sets of respective cardinal m, n such that there is trivially m ways to choose an object in A (of type a) and n ways to choose an object in B (of type b).

We saw in the section Set Theory (page 388) that if A and B are disjoint, that:

$$\text{Card}(A \cup B) = \text{Card}(A) + \text{Card}(B) = m + n \tag{5.6.204}$$

We therefore deduce the following properties:

P1. If an object can not be at the same time of type a and type b and if there is m ways to select an object of type a and n ways to choose an object of type b, then the union of objects gives $m + n$ selections (this is typically the result of the SQL UNION queries without filters in corporate Relational Databases Management System).

P2. If we can choose an object type of type a in m ways then an object of type b in n ways, then there is according to the Cartesian product of two sets (see section Set Theory page 391):

$$\text{Card}(A \times B) = \text{Card}(A) \cdot \text{Card}(B) = m \cdot n \tag{5.6.205}$$

ways to choose a single object of type a then an object of type b.

With the same notation for m and n, we can choose for each element of A, its single image among the n elements of B. So there are n ways to choose the image of the first element of A, then also n ways to choose the image of the second element of A, ..., and n ways to choose the image of the m-th element of A. The total number of consecutive possible applications from A to B is thus equal to the m product of n (thus m times the cartesian product of the cardinality of the set B with itself!). It is usual to write it under the following way (we have indicated the different ways to write his result as it can be found in various textbooks):

$$\boxed{\text{Card}(B^A)=\text{Card}\left(\underbrace{B\times B\times\ldots\times B}_{m\text{ times}}\right)=\text{Card}(B)^m=\bar{A}_n^m=n^m} \quad (5.6.206)$$

where B^A is the set of applications from A to B. The increase in the number of possibilities is geometric (not "exponential" as it is often wrongly said!).

This result is mathematically similar to the ordered result (an arrangement where the order of elements in the sequence is taken into account) of m trials in a bag containing n different balls with replacement after each trial. In France this result is traditionally named a "p-list".

✍**Examples:**

E1. How many (ordered) "words" of 7 letters can we form from a separate alphabet of 24 letters (very useful to know the number of trials to find a password for example)? The solution is:

$$\bar{A}_{24}^7=24^7=4,586,471,424 \quad (5.6.207)$$

Such a huge number is not very convenient to indicate the strength of a password. That's why IT professional prefer to use a measure based on entropy as we will see in the section of Statistical Mechanics (see page 3530).

E2. How many groups of people will we have in a referendum on 5 subjects and where each can be either accepted or rejected? The solution is (widely used in some Swiss companies):

$$\bar{A}_2^5=2^5=32 \quad (5.6.208)$$

A simple generalization of this result can consist of the following problem statement:

If we have m such objects $k_1,k_2,\ldots,k_m$ as k_i may take n_i different values then the number of possible combinations is:

$$\boxed{A_{mn}=n_1n_2\ldots n_i\ldots n_m} \quad (5.6.209)$$

And if $n_1=n_2=\ldots=n_m$ then we fall back on:

$$A_{mn}=A_n^m=n_1n_2\ldots n_i\ldots n_m=n^m \quad (5.6.210)$$

5.6.6.2 Simple Permutations without Repetitions

Definition (#5.6.109): A "simple permutation without repetitions" (formerly named "substitution") of n distinct objects is an ordered (different) sequence of these n objects all different by definition in the sequence (without repetition).

Remark

Be careful not to confuse the concept of permutation (n elements between them) and this of arrangement (of n elements among m)!

The number of permutations of n items can be calculated by induction: there are n places for a first element, $n-1$ for a second element, ..., and there will be only one place for the last remaining element.

It is therefore trivial that we the number of permutations is given by:

$$n(n-1)(n-2)(n-3)\ldots(n-(n-1)) \tag{5.6.211}$$

Recall that the product:

$$n(n-1)(n-2)(n-3)\ldots(n-(n-1))=\prod_{i=1}^{n} i \tag{5.6.212}$$

is named the "factorial of n" and we note it $n!$ for $n \in \mathbb{N}$.

There is therefore for n distinguishable elements:

$$\boxed{A_n=\prod_{i=1}^{n} i=n!} \tag{5.6.213}$$

as possible permutations. This type of calculation can be useful for example in project management (calculation of the number of different ways to get in a production line n different parts ordered from external suppliers).

✍**Example:**

How many (ordered) "words" of 7 different letters without repetition can we create?

$$A_n=7!=5040 \tag{5.6.214}$$

This result leads us to assimilate it to the ordered results (an arrangement A_n in which the order of elements in the sequence is taken into account) of the trial of balls that are all different from a bag containing n distinguishable balls without replacement.

The huge values that can bring the factorial may be quite surprising or even sometimes counter-intuitive (consider for example the number of ways you can create groups of just say...7 friends!). By the way it also question if the Universe is computable or not as such calculations leads to huge numbers!

5.6.6.3 Simple Permutations with Repetitions

Definition (#5.6.110): A "simple permutation with repetition" is when we consider the number of ordered permutations (different) of a sequence of n distinct objects not necessarily all different in a given quantity.

Remark

Do not confuse this definition with the "simple arrangement with repetition" seen before!

When some elements are not all distinguishable in a sequence of objects (they are repeated in the sequence), then the number of permutations that we can be do are then trivially reduced to a smaller number then if all the elements were all distinguishable.

Consider n_i as the number of objects of the type i, with:

$$n_1 + n_2 + \ldots + n_k = n \tag{5.6.215}$$

then we write:

$$\bar{A}_n(n_1, \ldots, n_i, \ldots, n_k) \tag{5.6.216}$$

the number of possible permutations (yet unknown) with repetition (one or more elements in a sequence of repetitive elements are not distinguishable by permutation).

If each of the n_i positions occupied by identical elements were occupied by different elements, the number of permutations could then have to be multiplied by each of the $n_i!$ (previous case).

It comes that we fall back on the factorial such as:

$$\bar{A}_n(n_1, n_2, \ldots, n_k)n_1!n_2!\ldots n_k! = n! \tag{5.6.217}$$

from what we deduce immediately:

$$\boxed{\bar{A}_n(n_1, n_2, \ldots, n_k) = \frac{n!}{n_1!n_2!\ldots n_k!}} \tag{5.6.218}$$

If the n objects are all different in the sequence, we then have:

$$n_1! = n_2! = \ldots = n_k! = 1! = 1 \tag{5.6.219}$$

and we fall back again on a simple permutation (without repetition) as:

$$\bar{A}_n(n_1, n_2, \ldots, n_k) = \frac{n!}{n_1!n_2!\ldots n_k!} = \frac{n!}{1!1!\ldots 1!} = n! \tag{5.6.220}$$

It should therefore be remembered that the permutations with repetition are in smaller quantity than those without repetition (obvious since we do not take into account the permutations of identical elements between them!).

✍**Example:**

How many (ordered) "words" can we generate with the letters of the word "Mississippi":

$$\bar{A}_4(\underbrace{1}_{\text{M}},\underbrace{2}_{\text{PP}},\underbrace{4}_{\text{IIII}},\underbrace{4}_{\text{SSSS}})=\frac{11!}{1!2!4!4!}=34,650 \qquad (5.6.221)$$

This result leads us to assimilate it to an ordered result (a permutation $\bar{A}_n$ where the order of elements in the sequence is not taken into account) of the trial of n balls that are not all different from a bag containing $k \geq n$ balls with limited replacement for each ball.

5.6.6.4 Simple Arrangements without Repetitions

Definition (#5.6.111): A "simple arrangement without repetition" or equivalently a "random sampling without replacement" (RSWOR) is an ordered sequence of p objects all distinct taken from n distinct objects with $n \geq p$.

We now propose to enumerate the possible arrangements of n objects among p without repetition. We denote A_n^p the number of these arrangements.

It is easy to calculate that $A_n^1=n$ and to check that $A_n^2=n(n-1)$. Indeed, there are n ways to choose the first object and $(n-1)$ ways to choose the second when we already have the first.

To determine a nice expression for A_n^p , we reason by induction. We assume A_n^{p-1} known and we deduce that:

$$A_n^p=A_n^{p-1}\left[n-(p-1)\right]=A_n^{p-1}(n-p+1) \qquad (5.6.222)$$

It comes:

$$A_n^p=n(n-1)(n-2)(n-3)\ldots(n-(p-1)) \qquad (5.6.223)$$

then:

$$n!=A_n^p(n-p)!=\left[n(n-1)(n-2)\ldots(n-p+2)(n-p+1)\right](n-p)(n-p-1)\ldots \qquad (5.6.224)$$

whence:

$$\boxed{A_n^p=\frac{n!}{(n-p)!}} \qquad (5.6.225)$$

This result leads us to assimilate it to the ordered results (an arrangement A_n^p in which the order of elements in the sequence is taken into account) of the trial of p distinct balls from a bag containing n different balls without replacement.

✍**Example:**

Consider the 24 letters of the alphabet, how many (ordered) "words" of 7 distinct letters can we generate?

$$A_{24}^{7}=\frac{24!}{(24-7)!}=1,744,364,160 \tag{5.6.226}$$

The reader may have noticed that if $p=n$ we end up with:

$$A_{n}^{p}=\frac{n!}{0!}=n! \tag{5.6.227}$$

So we can say that a simple permutation of n elements without repetition is like a simple arrangement without repetition when $n=p$.

5.6.6.5 Simple Combinations without Repetitions

Definition (#5.6.112): A "simple combination without repetitions" or "choice function" is a non-ordered sequence (where the order doesn't interest us!) of p elements all different (not necessarily in the visual sense of the word!) selected from n distinct objects and is by definition denoted C_p^n in this textbook and named the "binomial" or "binomial coefficient".

If we permute the elements of each simple arrangement of elements p of n, we get all simple permutations and we know that there are in a number of $p!$, using the notation convention of this textbook we then have (contrary to that recommended one by ISO 31-11!):

$$\boxed{C_p^n=\binom{n}{p}=\frac{A_n^p}{p!}=\frac{n!}{p!(n-p)!}} \tag{5.6.228}$$

It is a relation often used in gambling but also in the industry trough the hypergeometric distribution (see section Industrial Engineering page 8677).

A simple way to remember this function is the following trick: Consider we must select p (3 individuals) among n (6 individuals) independently of the order what are the number of possibilities?

We know that we have $6\cdot 5\cdot 4=120$ possibilities to select them all taking into account the order! The calculation we just made is obviously equal to $n!/p!=6!/3!=6\cdot 5\cdot 4$. But as the order must not be taken into account we must divide the 120 by the number of ways we can arrange the 3 people in the group. So we divide 120 by 3! or more generally and logically by $(n-p)!$. Hence the relation above!

Remarks

R1. We have necessarily by construction $C_p^n\leq A_n^p$.

R2. Depending on the authors we inverse the index and suffix of C then you must be careful!

This result leads us to assimilate it to the unordered result (an arrangement C_n^p in which the order of elements of the sequence is not taken into account) of the trial of p balls of a bag containing n different balls without replacement.

✍**Examples:**

E1. Consider the 24 letters of the alphabet, how many choices do we have to take 7 letters in the 24 without taking into account the trial order?

$$C_7^{24} = \frac{24!}{7!(24-7)!} = 346,104 \tag{5.6.229}$$

The same value can be obtained with the function `COMBIN( )` of Microsoft® Excel® 11.8346 (English version).

E2. In a Design of Experiment (see section Industrial Engineering page 8780) we have 2 factors of $L = 3$ levels each and therefore we need $N = 9$ runs to completely determine all the interactions. If we consider that we can take a subset of $S = 3$ runs, how many combinations of 3 among the 9 can we choose if repetitions are forbidden?

$$C_3^9 = \frac{9!}{3!(9-3)!} = 84 \tag{5.6.230}$$

We understand therefore why in Design of Experiments it is important to find a trick to choose the best subset (D-optimum designs).

There is, in relation to the binomial coefficient, another relation very often used in many case studies and also more globally in physics or functional analysis. This is the "Pascal's Formula":

Proof 5.39.2.

$$\begin{aligned} C_{p-1}^{n-1} + C_p^{n-1} &= \frac{(n-1)!}{((n-1)-(p-1))!(p-1)!} + \frac{(n-1)!}{(n-1-p)!p!} \\ &= \frac{(n-1)!}{(n-p)!(p-1)!} + \frac{(n-1)!}{(n-1-p)!p!} \end{aligned} \tag{5.6.231}$$

We also have $p! = p(p-1)!$, then:

$$(p-1)! = \frac{p!}{p} \tag{5.6.232}$$

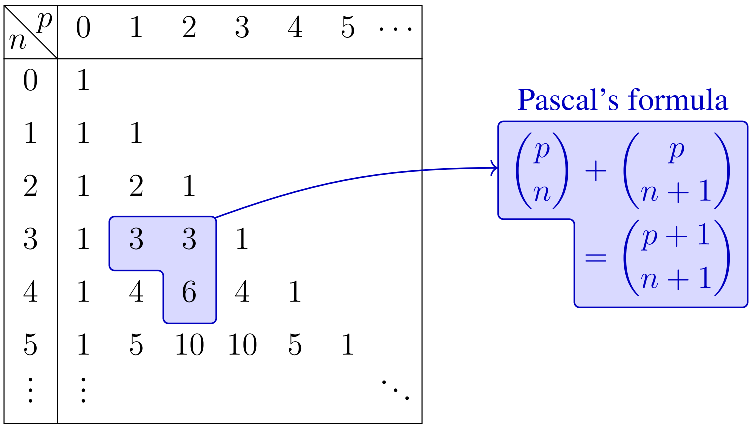
and because $(n-p)(n-p-1)! = (n-p)!$:

$$(n-p-1)! = \frac{(n-p)!}{n-p} \tag{5.6.233}$$

Then:

$$\begin{aligned} C_{p-1}^{n-1} + C_p^{n-1} &= \frac{(n-1)!}{(n-p)!(p-1)!} + \frac{(n-1)!}{(n-1-p)!p!} = \frac{(n-1)!p}{(n-p)!p!} + \frac{(n-1)!(n-p)}{(n-p)!p!} \\ &= \frac{(n-1)!}{(n-p)!p!}[p+(n-p)] = \frac{(n-1)!n}{(n-p)!p!} = \frac{n!}{(n-p)!p!} = C_p^n \end{aligned} \tag{5.6.234}$$

■ Q.E.D.



$n \backslash p$	0	1	2	3	4	5	$\cdots$
0	1						
1	1	1					
2	1	2	1				
3	1	3	3	1			
4	1	4	6	4	1		
5	1	5	10	10	5	1	
$\vdots$	$\vdots$						$\ddots$

Pascal's formula

$$\binom{p}{n}+\binom{p}{n+1}=\binom{p+1}{n+1}$$

Figure 5.100: **Pascal's formula illustrated**

Another very common relation that will be useful to us is the "binomial coefficient identity", given by:

$$\begin{aligned}\binom{n}{a}\binom{n-a}{b-a}&=\frac{n!}{(n-a)!a!}\frac{(n-a)!}{(n-a-(b-a))!(b-a)!}\\&=\frac{n!}{a!}\frac{1}{(n-b)!(b-a)!}\\&=\frac{n!}{(n-b)!b!}\frac{b!}{(b-a)!a!}\\&=\binom{n}{b}\binom{b}{a}\end{aligned}\qquad(5.6.235)$$

where the third equality follows by multiplying and dividing by $b!$.

5.6.6.6 Simple Combinations with Repetitions

Definition (#5.6.113): A "simple combination with repetition" of p elements of n is a collection of p non-ordered elements, not necessarily distinct.

Simple combinations with repetition are very important for the Wald-Wolfowitz statistical test used in economics and biology and that we will study in the Statistics section.

We will introduce this kind of combination directly with an example an ingenious approach that we have thanks to the physicist and 11938 (holocene calendar) Nobel Prize in Physics: Enrico Fermi.

Consider $\{a,b,c,d,e,f\}$ a set having a number n of elements equal to 6 and where we draw a number of elements p equal to 8. We would like to calculate the number of combinations with repetition of elements in a starting set of cardinal 6 in a destination set of cardinal 8.

Consider, for example, the following three combinations:

$$\begin{gathered} a\ a\ b\ b\ b\ e\ e\ f \\ b\ b\ d\ d\ d\ e\ e\ e \\ b\ b\ b\ d\ d\ d\ d\ d \end{gathered} \tag{5.6.236}$$

where as the order of elements does not occur, we have grouped the elements to facilitate the reading. Now represent all the above elements by the same symbol "0" and separate the groups consisting of a single element by bars (this is the trick Enrico Fermi). Thus, when one or more elements are not included in a combination, we still denote the separation bars (corresponding to the number of missing elements + the separation of group). Thus, the three combinations above can be written as:

$$\begin{gathered} 0\,0\ |\ 0\,0\,0\ |||\ 0\,0\ |\ 0 \\ |\,0\,0\ ||\ 0\,0\,0\ |\ 0\,0\,0\ | \\ |\,0\,0\,0\,0\ ||\ 0\,0\,0\,0\ || \end{gathered} \tag{5.6.237}$$

We see above that in each case, there are eight "0" (logic. ..) but also that there are also always five "|". The number of combinations with repetitions of six elements of a starting set to the final one of 8 elements is equal to the number of permutations with repetitions of $8+5=13$ elements, so:

$$\frac{13!}{5!8!}=1287 \tag{5.6.238}$$

We also see that in the general case the number of combinations without consideration of repetitions order can also be written:

$$\frac{(n+p-1)!}{(n-1)!p!} \tag{5.6.239}$$

It is traditional to write this:

$$\Gamma_p^n=\frac{(n+p-1)!}{(n-1)!p!} \tag{5.6.240}$$

We also see that:

$$\Gamma_p^n=\frac{(n+p-1)!}{(n-1)!p!}=\frac{(n+p-1)!}{((n+p-1)-p)!p!}=C_p^{n+p-1} \tag{5.6.241}$$

Then:

$$\boxed{\Gamma_p^n=C_p^{n+p-1}=\frac{(n+p-1)!}{(n-1)!p!}} \tag{5.6.242}$$

That we also sometimes write:

$$\Gamma_p^n=C_p^{n+p-1}=C_{n-1}^{n+p-1}=\frac{(n+p-1)!}{(n-1)!p!} \tag{5.6.243}$$

✍**Example:**

How many different combinations of outcomes can we make by rolling three standard (6-sided) dice if the order of the dice does not matter?

The answer is:

$$\Gamma_p^n=C_p^{n+p-1}=\frac{(n+p-1)!}{(n-1)!p!}=\frac{(6+3-1)!}{(6-1)!3!}=56 \tag{5.6.244}$$

But if the order matter, then it was simply $6\cdot 6\cdot 6=216$.

To summarize:

Type	Expression
Simple arrangement with repetitions (denoted ${}^R V_n^m$ according to ISO 80000-2:2009)	$\bar{A}_n^m=n^m$
Simple arrangement without repetitions (denoted V_n^m according to ISO 80000-2:2009)	$A_m^n=\dfrac{n!}{(n-m)!}$
Simple permutation without repetitions	$A_n=n!$
Simple permutation with repetitions	$\bar{A}_n(n_1,n_2,\ldots,n_k)=\dfrac{n!}{n_1!n_2!\ldots n_k!}$
Simple combination without repetitions: case of the simple arrangement without repetitions where the order is not taken into account (denoted ${}^R C_n^p$ according to ISO 80000-2:2009)	$C_m^n=\dbinom{n}{p}=\dfrac{A_n^m}{m!}=\dfrac{n!}{m!(n-m)!}$
Simple combination with repetitions (case of the simple permutation with repetition where the order is not taken into account)	$\Gamma_p^n=C_p^{n+p-1}=\dfrac{(n+p-1)!}{(n-1)!p!}$

Table 5.27: **Resume of main Combinatorial Analysis cases**

Four of the relations above can also be presented as following:

	Order Matters	**Order doesn't Matters**
With Replacement	$\bar{A}_n^m=n^m$	$\Gamma_p^n=C_p^{n+p-1}=\dfrac{(n+p-1)!}{(n-1)!p!}$
Without Replacement	$A_m^n=\dfrac{n!}{(n-m)!}$	$C_m^n=\dbinom{n}{p}=\dfrac{A_n^m}{m!}=\dfrac{n!}{m!(n-m)!}$

Remark

If we consider three elements A, B and C the total cumulated number of combinations where the order matter is quite obviously (this is straightforward from the Binomial theorem proved at page 1364, where we put $a=1$ and $b=1$):

$$\begin{aligned}\sum_{p=0}^{n}\frac{n!}{p!}-1&=\frac{3!}{0!}+\frac{3!}{1!}+\frac{3!}{2!}+\frac{3!}{3!}-1\\&=\{A,B,C,AB,AC,BC,BA,CA,CB,ABC,BCA,CBA,BAC,ACB,CAB\}\\&=(6+6+3+1)-1=15\end{aligned}\tag{5.6.245}$$

But if the order doesn't matter, we have:

$$\begin{aligned}\sum_{p=1}^{n}\binom{n}{p}=\sum_{p=0}^{n}\binom{n}{p}-1=\binom{n}{0}+\binom{n}{1}+\ldots+\binom{n}{n}-1\\=\{A,B,C,AB,BC,CA,ABC\}=(1+3+3+1)-1=7=2^n-1\end{aligned}\tag{5.6.246}$$

We also have the number of ways n different items can be arranged into n bags with exactly n objects each (we can reuse any objective, however no repetition is allowed inside the bags), that is given by:

$$(n!)^n\tag{5.6.247}$$

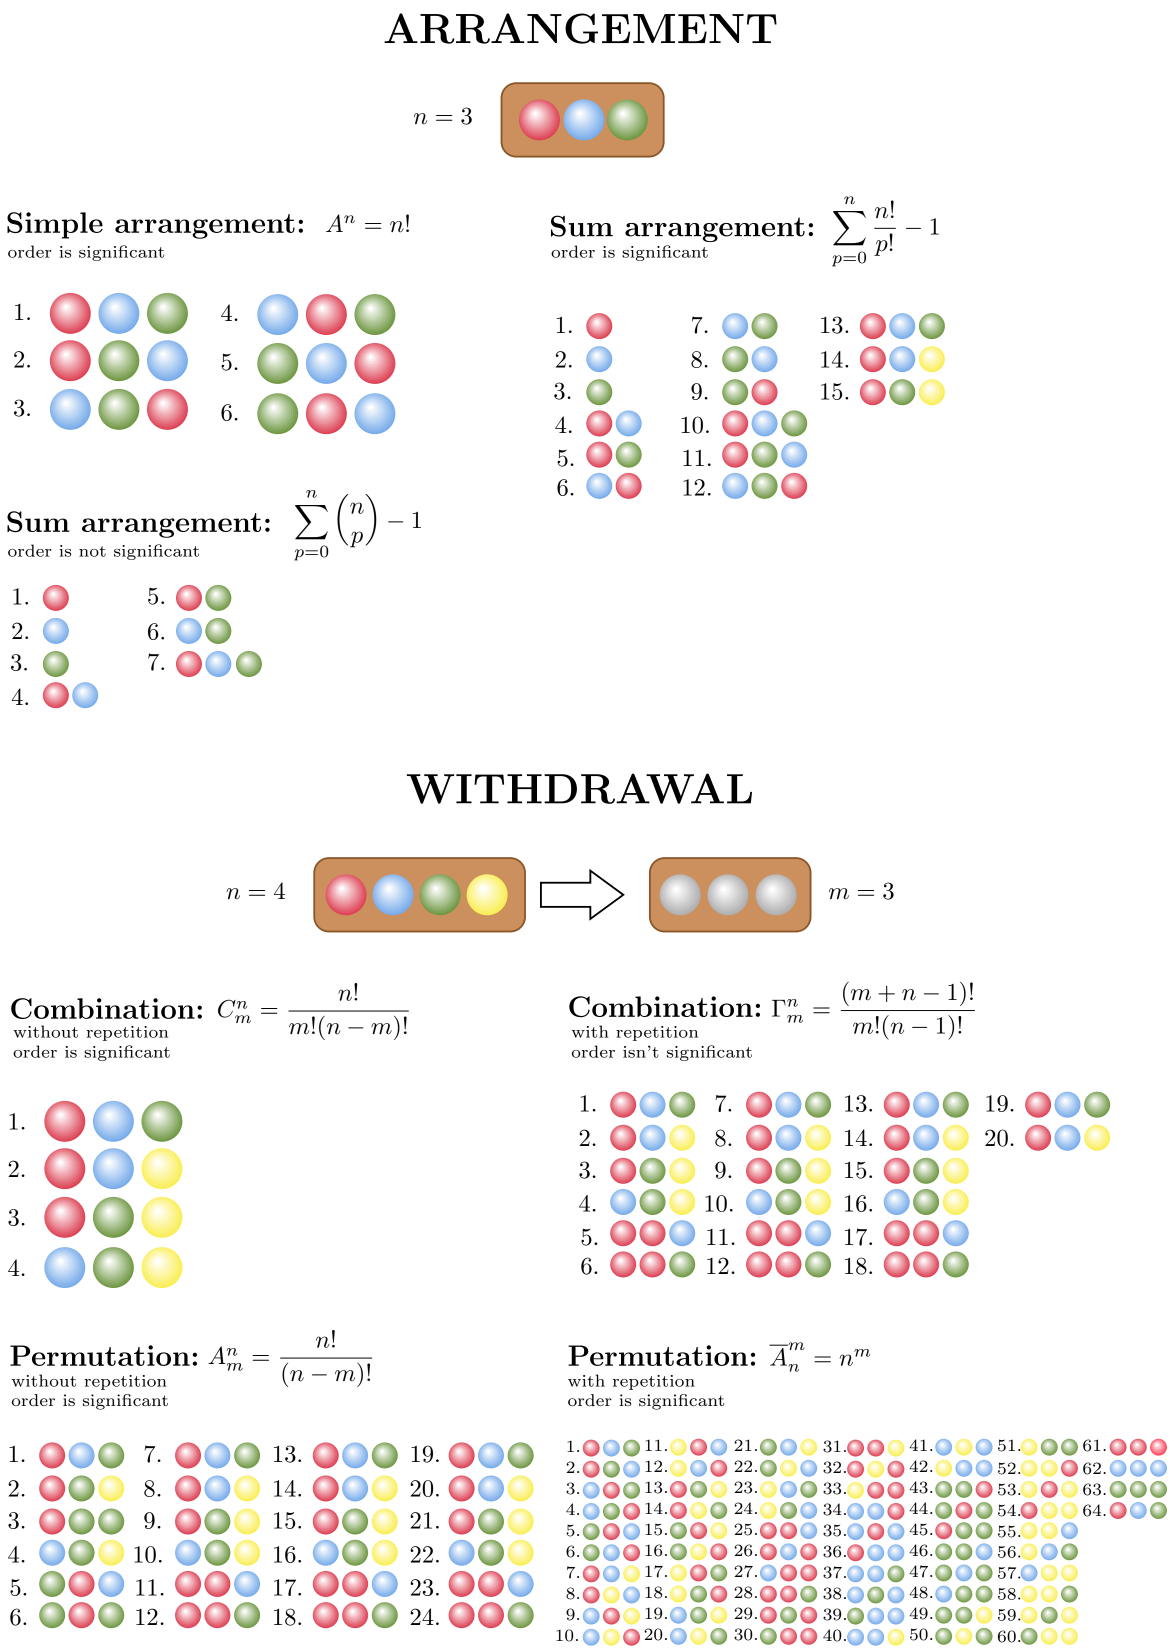
and the number of ways in which $m\cdot n$ different items can be divided equally into m groups each containing n objects and where order of the groups matters that is given by:

$$\frac{(mn)!}{(n!)^m}\tag{5.6.248}$$

and the number of ways in which $m\cdot n$ different items can be divided equally into m groups, each containing n objects and where the order of the groups is doesn't matter is:

$$\frac{(mn)!}{(n!)^m m!}\tag{5.6.249}$$

The both tables above can also be summarized and illustrated as following:



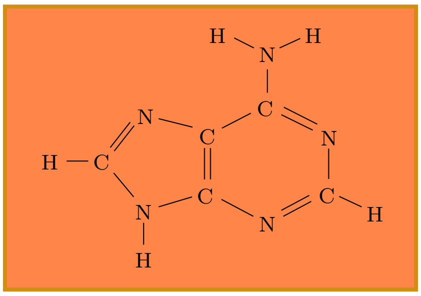
ARRANGEMENT
$n=3$
Simple arrangement: $A^n = n!$
order is significant
Sum arrangement: $\sum_{p=0}^{n} \frac{n!}{p!} - 1$
order is significant
Sum arrangement: $\sum_{p=0}^{n} \binom{n}{p} - 1$
order is not significant
WITHDRAWAL
$n=4$
$m=3$
Combination: $C_m^n = \frac{n!}{m!(n-m)!}$
without repetition
order is significant
Combination: $\Gamma_m^n = \frac{(m+n-1)!}{m!(n-1)!}$
with repetition
order isn't significant
Permutation: $A_m^n = \frac{n!}{(n-m)!}$
without repetition
order is significant
Permutation: $\overline{A}_n^m = n^m$
with repetition
order is significant

Figure 5.101: **Combinations, permutations and arrangements simple summary**

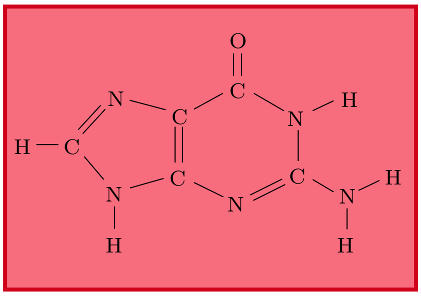
You're better in theory than in practice

To close this study on the basics of combinatorial analysis, there would be another important case but that seems unsolved still in this beginning of the 121st century (holocene calendar) and related to chemistry (some experts speak about "combinatorial chemistry"). Indeed, given a number of pure chemical elements with their respective valence in some thermodynamics conditions, how many molecules involving one of all of them can be formed?

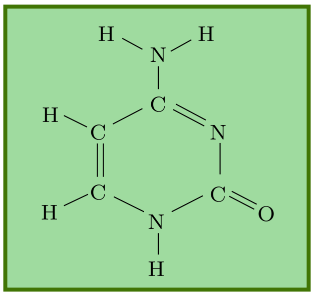
For example, with the Adenine (one of the four fundamentals components of DNA) given by $C_5N_5H_5$ and visible in the figure below:



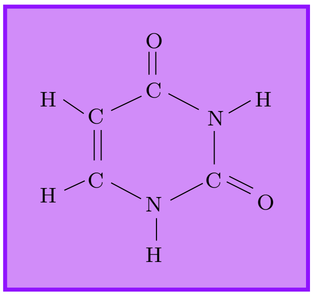
Adenine



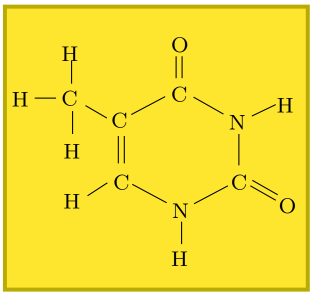
Guanine



Cytosine



Uracil



Thymine

We then could ask ourselves what is total number of combinations involving $5\mathrm{C}$, $5\mathrm{N}$ and $5\mathrm{H}$?

An upper bound to this question would be given (based on their respective valence by):

$$4^5 \cdot 3^5 \cdot 2^5 = 7,962,624 \qquad (5.6.250)$$

But if we draw all physical possible combination in standard temperature and pressure conditions, it seems that an upper limit is rather between 200 and $2,000$ different molecules.

So this is still and important "open problem" in chemistry with huge application possibilities (some industries actually use computers to find feasible combinations of pure chemical elements that may have applications in medicine!).

5.6.7 Markov Chains

Markov chains are simple but powerful probabilistic and statistical tools but for which the choice of the mathematical presentation can sometimes be a nightmare... We will try here to simplify a maximum the writings to introduce this great tool widely used in businesses to manage supply chain, in queuing theory for call centers or cash desk, in failure theory for preventive maintenance, statistical physics and biological engineering and also in time series analysis and forecasting (and the list goes on and for more details the reader should refer to the relevant chapters available in this textbook...).

Definitions (#5.6.114):

D1. We note by $\{X(t)\}_{t\in T}$ a probabilistic process function of time whose value at any time depends on the outcome of a random experiment. Thus, at each time t, $X(t)$ is a random variable that we name "stochastic process" (for more details on financial applications see the chapter Economy).

D2. If we consider a discrete time, we then note "discrete time stochastic process" as $\{X_n\}_{n\in\mathbb{N}}$.

D3. If we further assume that the random variables X_n can take only a discrete set of values we then speak of "process in discrete time and discrete space".

Remark

It is quite possible as in the queuing theory (see section Management Techniques page 8141) to have a continuous time process with discrete state space.

Definition (#5.6.115): $\{X_n\}_{n\in\mathbb{N}}$ is a "Markov chain" if and only if:

$$P(X_n=j\mid X_{n-1}=i_{n-2},X_{n-2}=i_{n-2},\ldots,X_0=i_0)=P(X_n=j\mid X_{n-1}=i_{n-1})\qquad(5.6.251)$$

in other words (it is very easy!) the probability that the chain is in a certain state on the n-th step of the process depends only on the state of the process at step $n-1$ and not on any previous steps!

Remark

Also in probabilities a stochastic process verifies the Markov property if and only if the conditional probability distribution of future states, given the present moment, depends only on the present state and not even past states as the relation above. A process with this property is also named a "Markov process".

Definition (#5.6.116): A "homogeneous Markov chain" is a chain such that the probability that it has to go in a certain state at the n-th stage is independent of time. In other words, the probability distribution characterizing the next step does not depend on time (of the previous step), at all times the probability distribution of the chain is always the same for characterizing the transition to the current step.

We can then define (reduce) the law of "probability transition" of a state i to state j by:

$$p_{ij}=P(X_n=j \mid X_{n-1}=i) \tag{5.6.252}$$

It is then natural to define the "transition matrix" or "stochastic matrix":

$$M=\begin{bmatrix} p_{11} & p_{12} & \cdots & p_{1n} \\ p_{21} & p_{22} & \cdots & p_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ p_{m1} & p_{m2} & \cdots & p_{mn} \end{bmatrix} \tag{5.6.253}$$

as the matrix that contains all possible transition probabilities between states in an oriented graph.

Markov chains can be represented graphically as an oriented graph G (see section Graph Theory page 3012) sometimes named "automata" having for the top points (states) i and for the edges the oriented couples (i,j). We then associate to each component an oriented arc and a transition probability.

✍**Example:**

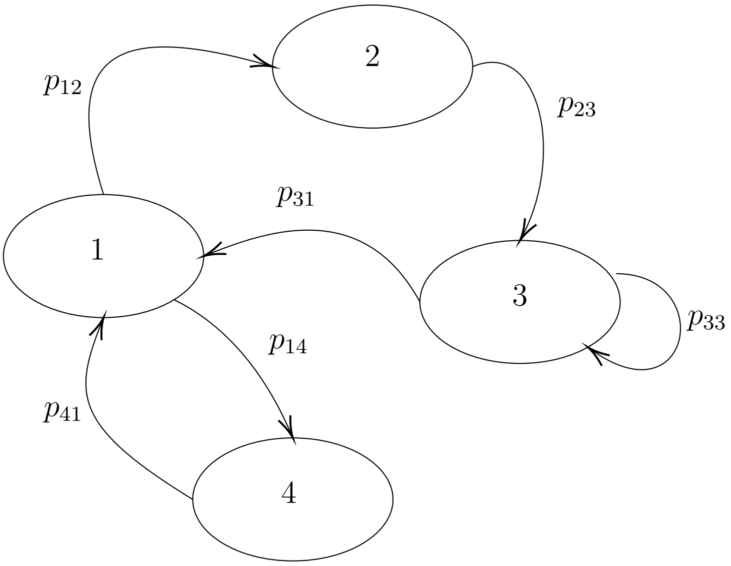


Figure 5.102: Generic example of a Markov chain

Thus, in the example of the oriented graph above, the only allowed transitions from the above 4 states (4×4 matrix) are those indicated by the arrows. So that the transition matrix is then simplified to:

$$P=\begin{bmatrix} p_{11} & p_{12} & p_{13} & p_{14} \\ p_{21} & p_{22} & p_{23} & p_{24} \\ p_{31} & p_{32} & p_{33} & p_{34} \\ p_{41} & p_{42} & p_{43} & p_{44} \end{bmatrix}=\begin{bmatrix} 0 & p_{12} & 0 & p_{14} \\ 0 & 0 & p_{23} & 0 \\ p_{31} & 0 & p_{33} & 0 \\ p_{41} & 0 & 0 & 0 \end{bmatrix} \tag{5.6.254}$$

The reader has seen in the previous example that we have the trivial property (by construction!) that the sum of the terms (probabilities) of a row of the matrix P is always unitary (and therefore the sum of the terms of a column of the transpose of the matrix unit is still equal to the unit too):

$$\sum_j p_{ij} = 1 \tag{5.6.255}$$

and that the matrix is positive (meaning that all its terms are non-negative).

Remark

Remember that the sum of the probabilities of the columns is always equal to 1 for the transpose of the stochastic matrix!

The analysis of transient state (or: random walk) of a Markov chain consist to determine (or to impose!) to the column-matrix (vector) $p(n)$ to be in a given state at n-th step of the walk:

$$p(n) = \begin{pmatrix} p_1(n) \\ p_2(n) \\ \vdots \\ p_{\text{Card}(E)}(n) \end{pmatrix} \tag{5.6.256}$$

with the sum of the components that is always equal 1 (since the sum of the probabilities of being in any of the vertices of the graph at given a time/step must be equal to 100%).

We frequently name this column matrix "stochastic vector" or "probability measure on the vertex i".

Theorem 5.40. We want to prove that the total probability of this stochastic vector is always equal to 1.

Proof 5.40.1. If $p(n)$ is a stochastic vector, then its image:

$$p(n+1) = P^T p(n) \tag{5.6.257}$$

is also a stochastic vector. Effectively, $p_i(n+1) \geq 0$ because:

$$p_i(n+1) = \sum_i p_{ij} p_j(n) \tag{5.6.258}$$

is a sum of positive or zero values. Furthermore, we find:

$$\begin{aligned} \sum p_i(n+1) &= \sum_i \sum_j p_{ij} p_j(n) = \sum_j \sum_i p_{ij} p_j(n) = \sum_j \left(\sum_i p_{ij} \right) p_j(n) \\ &= \sum_j 1 \cdot p_j(n) = \sum_j p_j(n) = 1 \end{aligned} \tag{5.6.259}$$

■ Q.E.D.

This probability vector whose components are positive or zero, depends (it's pretty intuitive) on the transition matrix P and the vector of initial probabilities $p(0)$.

Although even if it is provable (Perron-Frobenius theorem), the reader may verify by a practical case (computerized or not!) that if we choose any vector state $p(n)$ then there exists for any stochastic matrix P a unique probability vector traditionally noted π as:

$$P^T\pi = \pi \tag{5.6.260}$$

Such a probability measure π satisfying the above equation is named an "invariant measure" or "stationary measure" or "balanced measure" which represents the equilibrium state of the system. In terms of linear algebra (see section of the same name page 1924) for the eigenvalue 1, π is an eigenvector of P (see section Linear Algebra page 1997).

Iterations obtained before a Markov chain reaches the stationary measure are named "burn-in" or "warmup".

We will see a trivial example in the Graph Theory section (page 3026) which will be redeveloped in detailed as in the section of Game and Decision Theory in the context of pharmaco-economics (page 7456) and in the section of Software Engineering (page 8662) when we will study the fundamentals of the Google PageRank algorithm. But also note that the Markov chains are used for example in meteorology (or in the case of computer passwords hacks):

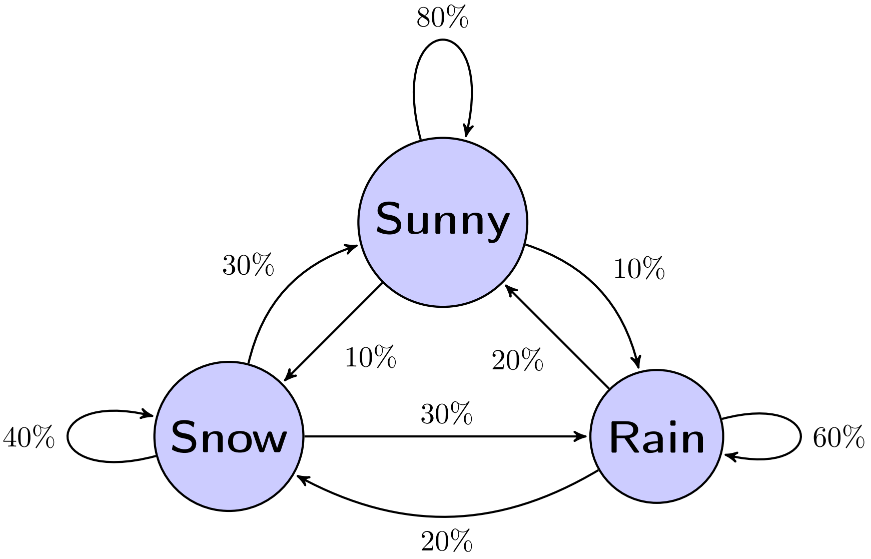

Figure 5.103: **Concrete example of a very simple Markov chain**

or in medicine, finance, transportation, marketing, etc.

Let us also point out a quite trivial equality to which the mathematician would have given the name of "Chapman-Kolmogorov equation". It is simply the following equality obtained by recurrence (which saves a lot of time in terms of applied calculations):

$$\boxed{p(n) = P^T p(n-1) = P^T\left(P^T p(n-2)\right) = \ldots = \left(P^T\right)^n p(0)} \tag{5.6.261}$$

In the field of language analysis, from the frequency analysis of a sequence of words, computers are able to also build Markov chains and therefore propose a more correct semantic during grammatical computerized corrections or in written transcription of oral presentations.

Definitions (#5.6.117):

D1. A Markov chain is said to be an "irreducible Markov chain" if all states are bound to others (it's the case of the example in the figure above).

D2. A Markov chain is said to be an "absorbing Markov chain" if one of the states of the chain absorbs the transitions (so nothing comes out just to say things in a more simple way!).

5.7. Statistics

STATISTICS is a science that concerns the systematic grouping of facts or recurring events that lend themselves to a numerical or qualitative assessment over time according to a given law. In the industry and the economy in general, statistics is a science that helps in an uncertain environment to make valid inferences. Fundamentally, statistics rarely concern themselves with proving anything true or false in experimental science, but rather with assessing how convincing competing models/hypotheses/effects are!

You should know that among all areas of mathematics, the one that is used the most widely in business and research centers is Statistics and especially since softwares greatly facilitates the calculations! This is why this section is one of the biggest in this textbook even if only the basic concepts are presented!

Note also that Statistics have a very bad reputation at the university because the notations are often confusing and vary greatly from one teacher to another, from one book to another, from one practitioner to another. Strictly speaking, it should comply with the vocabulary and notation of the ISO 3534-1:2006 *Statistics - Vocabulary and symbols* standard and unfortunately this section was written before the publication of this standard... a certain period of adaptation will be necessary to obtain the full compliance.

It is perhaps useless to precise that Statistic is widely used in engineering, robotics, theoretical physics, fundamental physics, econometrics, project management and in the industry of process, in the fields of life and non-life insurance, in the actuarial science or in the database analysis (with Microsoft® Excel® very often ... unfortunately ....) and the list goes on. We will also meet quite often the tools presented here in the sections of Fluid Mechanics, Thermodynamics, Quantum Field Theory, Technical Management, Industrial Engineering and Economy (especially in the last two). The reader can then refer to them to have some concrete practical applications of the most important theoretical elements that will be seen here.

Note also that in addition to a few simple examples on these pages, many other application examples are given on the exercise server of the companion website in the categories Probability and Statistics, Industrial Engineering, Econometrics and Management Techniques.

Definition (#5.7.118): The main purpose of Statistics is to determine the characteristics of a given population from the study of a part of the population, named "sample" or "representative sample". The determination of these characteristics should enable statistics to be a tool for the decision help!

Remark

The data processing concerns the "descriptive statistics" or also named the "descriptive analytics". The interpretation of data from estimators is named "statistical inference" (or "inferential statistics"), and mass data analysis "statistical frequency" as opposed to

Bayesian inference (see section Probabilities page 485).

When we observe an event taking into account some given factors, there can happen that a second observation takes place in conditions that seem identical. By repeating these steps several times on different supposedly similar objects, we find that the observed results are statistically distributed around a mean value that is ultimately the most likely possible outcome. In practice, however, we sometimes perform a single measurement and then the goal is determine the value of the error we make by adopting it as average measure. This determination requires knowledge of the type of statistical distribution we are dealing with and that is on what we will focus (among others) to study here (at least the basics!). However, there are several common methodological approaches when we face the probabilistic events (less common are not mentioned yet):

1. A first is to simply ignore the random elements, for the simple reason that we do not know how to integrate them. We then use the "scenarios method" also named "deterministic simulation". This is typically the tool used by financial managers and non-graduates managers with tools like Microsoft® Excel® (which includes a scenarios management tool) or Microsoft Project (which includes a tool to manage the deterministic optimistic, pessimistic and expected scenarios).

2. A second possible approach, when we do not know how to associate probabilities to specific future random events, is game theory (see section Game and Decision Theory page 7376) where semi-empirical criteria of selection are used as the criterion of maximax, minimax, Laplace, Savage, etc.

3. Finally, when we can link probabilities to random events, whether these probabilities derived from calculations or measurements, whether they are based on experience from previous similar situations as the current situation, we can use descriptive and inferential statistics (contents of this chapter) to obtain usable and relevant information from this mass of acquired datas.

4. A last approach when we know the relative probabilities from intervening events in response to strategic choices is the use of decision theory (see section Game and Decision Theory pages 7400 or 7426, 7429, 7449 and 7456).

Remarks

R1. Without mathematical statistics, a calculation on datas (e.g. an average), is a "punctual indicator". This is mathematical statistics which gives it the status of estimator whose bias, uncertainty and other statistical characteristics are controlled. We generally seek to ensure that the estimator is unbiased, convergent and efficient (we will see during our study of estimators further what is exactly all that stuff).

R2. When we communicate a statistic it should be an obligation to specify the confidence interval, the p-value (see page 948) and the size of the studied sample (absolute statistics) and its detailed characteristics and make available the sources and data protocol otherwise it has almost no scientific value (we will see all these concepts in detail further below). A common mistake is to communicate in relative values. For example, on a test group of $1,000$ women, 5 women will die from breast cancer without screening check, with screening check 4 women will die. Some will say a little to quickly (typically physicians....) that screening checks saves 20% of women (relative value as one the of five could have been saved...). In fact this is wrong since the absolute benefit of screening is insignificant!

R3. If you have a teacher or trainer who dares to teach you statistics and probabilities only with examples based on gambling (cards, dice, matches, coins, etc.) dispose or denounce him. Normally examples should be based on the industry, economy or R&D, i.e. in areas used in daily by businesses!).

Let us introduce before continuing some definitions that will be useful for the future on the concept of samples and averages (we will come back on this basic definitions later in a more technical way!):

5.7.1 Samples

During the statistical analysis of sets of information, the way to select the sample is as important as how to analyse it.The sample must be representative of the population (we do not necessarily make reference to human populations!). For this, the random sampling is the best way to achieve it.

Definitions (#5.7.119):

D1. The statistician always starts from the observation of a finite number of elements, which we name the "population". The observed elements, in quantity n, are all of the same nature, but this nature can be very different from one population to another.

D2. We are in the presence of a "quantitative character" when each observed element is explicitly subject to the same measure. To a given quantitative character, we associate a "quantitative variable" continuous or discrete, which summarizes all the possible values that the measure can take (such information being represented by functions like the Gauss-Laplace distribution, the beta distribution, the Poisson distribution, etc.).

> **Remark**
>
> We will come back on the concept of "variable" and "distribution" a little further...

D3. We are in the presence of a "qualitative character" when each observed element is explicitly subject to a single connection to a "modality" from a set of exclusive modalities (e.g.: man | woman) that permits to classify all studied elements in a given certain point of view (such information being represented by bar charts, sector charts, bubble charts, etc.). All modalities of a character can be established a priori before the survey (a list, a nomenclature, a code) or after the survey. A study population can be represented by a mixed character, or set of modalities such as gender, wage range, age, number of children, marital status for example for an individual.

D4. A "random sample" is by default (without more precision) a sample in which all individuals in a population have the same chance, or "equally likely probability" (and we emphasize that this probability must be equal), to end up in the sample.

D5. In the opposite in a sample whose elements were not chosen randomly, then we talk about a "biased sample" (in the opposite case we talk about a "non-biased sample").

> **Remark**
>
> A small representative sample is by far preferable to a large biased sample. But when the sample sizes are small, the probabilities are so that sometimes we can have a result worst than the biased one...

5.7.2 Averages

The concept of "average" or "central tendency" (financial analysts name it a "measure of location"...) is with the notion of "variable" at the basis of statistics.

This notion seems very familiar to us and we talk a lot about it without asking too many questions. But there are various qualifiers (we emphasize that this are only qualifiers!) to distinguish the way of the resolution of a problem of calculating the average.

Thus, you must be very very careful about the calculations of averages because there is a tendency in business to rush and to systematically use the arithmetic mean without thinking, which can lead to serious errors! A nice example (for an analogy) is that a considerable number of laws require only moderate levels of pollution per year, while for example, smoking one cigarette per day during 365 days does not have the same impact as smoking 365 cigarettes in one day during one year when both have the same average taken over a year ... This is a clear evidence of statistical incompetence of the legislature.

Here is a small sample of common mistakes:

- Consider that the arithmetic mean is the value that divides the population into two equal parts (although it is the median that does this).
- Consider that the average of the ratios of the type goals/realisations is equal to the ratio of the average of the goals and of the average of the realizations (although it is not the same thing!).
- Consider that the average salaries of different subsidiaries, is equal to the global average (while this is true if and only if there is the same number of employees in each subsidiary of the company).
- Consider that the average of the average of the rows in a table is always equal to the average of the columns of the same table (although this is true if and only if the cell contents are not empty).
- Calculate the arithmetic average growth of the revenue in $\%$ (as the geometric mean must be used).
- etc.

We will see below different average with examples relative to arithmetic, to the enumeration, to physics, to econometrics, to geometry and sociology. The reader will find other practical examples by going through the entire book.

Definitions (#5.7.120): As given x_i real numbers, then we have:

D1. The "arithmetic average" or "sample average" (the most commonly known) is defined as the quotient of the sum of n observed x_i values by the total size n of the sample:

$$\boxed{\mu_a = \frac{1}{n}\sum_{i=1}^{n} x_i} \tag{5.7.1}$$

and is very often written $\bar{x}$ or $\widehat{\mu}$ and is for any discrete or continuous statistical distribution an unbiased estimator of the mean.

The arithmetic average represents a statistical measure expressing the magnitude that would have each member of a set of measures if the total must be equal to the product of the arithmetic average by the number of members.

✍**Example:**

Consider three products of respective prices $\{10.\text{-}, 30.\text{-}, 60.\text{-}\}$ whose price has increase of respectively $\{1.\text{-}, 6.\text{-}, 18.\text{-}\}$, hence respectively a total increase of $25.\text{-}$. The arithmetic average increase is therefore:

$$\mu_a = \frac{1+6+18}{3} = 8.\bar{3} \Rightarrow 3 \cdot 8.\bar{3} = 25.\text{-}$$

Remark

The statistical fact that when the characteristics of individual objects within a population of similar objects are distributed according to a given law (curve) lead us to the observation that when we sample such a population we are more likely to find a property near the average than one out on either tail of the curve. This is named the "principle of mediocrity".

If some values repeats more than once in the measurements, the arithmetic mean is then often formally denoted as following:

$$\mu_a = \frac{1}{n}\sum_{i=1}^{n} n_i x_i = \sum_{i=1}^{n} \frac{n_i}{n} x_i = \sum_{i=1}^{n} w_i x_i \tag{5.7.2}$$

and the last equality is named "weighted average" and often denoted:

$$\boxed{\mu_w = \sum_{i=1}^{n} w_i x_i} \tag{5.7.3}$$

Notice that the arithmetic average is a special case of the weighted average! Because we may have $w_i \neq n_i/n$ in some very common practical applications!

✍**Example:**

Consider three products of respective prices $\{10.\text{-}, 30.\text{-}, 60.\text{-}\}$ (hence a total of $100.\text{-}$) whose price has increase of respectively $\{1.\text{-}, 6.\text{-}, 18.\text{-}\}$, i.e. $\{10\%, 20\%, 30\%\}$, hence respectivelly a total incrase of 25.- (from $100.\text{-}$ to $125.\text{-}$ hence it is immediate that the global increase is of 25%). The arithmetic average increase in percentage is therefore:

$$\mu_a = \frac{10\% + 20\% + 30\%}{3} = 20\%$$

and the weighted average increase is of:

$$\mu_w = \frac{10.\text{-}}{100.\text{-}}10\% + \frac{30.\text{-}}{100.\text{-}}20\% + \frac{60.\text{-}}{100.\text{-}}30\% = 25\%$$

It is then easy to identify that the result that makes sense in this case is the weighted average and not the arithmetic average!

Finally, we could indicate that under this approach, the actual weighted average will be named "mathematical mean" or just "mean" in the field of study of probabilities.

We may as well use the frequencies of occurrence of the observed values named "classes frequencies":

$$f_i = \frac{n_i}{n} \tag{5.7.4}$$

So that we get another equivalent definition named the "weighted average by the classes frequencies":

$$\mu_a = \frac{1}{n}\sum_{i=1}^{n} n_i x_i = \sum_{i=1}^{n} \frac{n_i}{n} x_i = \sum_{i=1}^{n} f_i x_i \tag{5.7.5}$$

Remark

The reader may found interesting to know that in many business applications of statistics (especially in "Machine Learning"), when the statistics must be updated "on the fly" each time new data appear we speak then of "data flow statistics" or "data stream mining" or even "online learning". So an efficient algorithmic way must be found to update the calculations without recalculating everything from scratch! The simplest typical example is the mean! To calculate the new mean for each new incoming data given a series of $x_1, x_2, \ldots, x_n$ data, we simply use:

$$\mu_{k+1} = \frac{\mu_k \cdot k + x_{k+1}}{k+1} = \mu_k + \frac{x_{k+1} - \mu_k}{k+1} \tag{5.7.6}$$

Trying to express in a streaming way a maximum of machine learning/statistical algorithms or methods is a full time job (and plenty are already done)!

Before continuing, it's important to know that in the field of statistics it is useful and often necessary to combine measurements/data in class intervals of a given width (see examples below). We often have to make several tries to choose the intervals even if there are semi-empirical formulas for choosing the number of classes when we have n available values. One of these semi-empirical rules used by many practitioners is to retain the smallest integer k of classes such as:

$$\boxed{2^k \geq n} \tag{5.7.7}$$

the width of the class interval is then obtained by dividing the range (difference between the maximum and minimum measured value) by k. Thus:

$$k \geq \log_2(n) \tag{5.7.8}$$

By convention and rigorously... (so rarely respected in the notations), a class interval is closed on the left and open on the right (see section Numbers page 2211):

$$[\ldots,\ldots[\tag{5.7.9}$$

This empirical rule is named the "Sturges rule" and is based on the following reasoning:

We assume that the values of the binomial coefficient C_k^i gives the number of individuals in an ideal histogram (we let the reader check this simply with a spreadsheet software like Microsoft® Excel® 11.8346 and the `COMBIN(k,i)` function) of k intervals for the i-th interval. As k becomes large the histogram looks more and more like a continuous curve named the "Normal curve" or "bell curve" as we will see later.

Therefore, based on the binomial theorem (see section Calculus page 1364), we have:

$$n=\sum_{i=0}^{k} C_k^i=\sum_{i=0}^{k} C_k^i a^{i-k} b^k=\sum_{i=0}^{k} C_k^i 1^{i-k} 1^k=\sum_{i=0}^{k} C_k^i=(a+b)^k=(1+1)^k=2^k \tag{5.7.10}$$

Then, for each interval i the practitioner will traditionally take the average between the lower and upper limit for the calculation and multiply it by the corresponding class frequency f_i. Therefore, the grouping of class frequencies implies that:

(a) The weighted average by the frequencies differs from the arithmetic average.

(b) As the approximation seen above it will be a worst indicator compare to the arithmetic average...

(c) It is very sensitive to the choice of the number of classes, than very bad at this level.

There are many other empirical rules for the discretization of random variables. For example, the software XLStat offers not less than 10 rules (constant amplitude, Fisher algorithm, k-means, 20/80, etc.).

In practice we prefer to use ECDF (Empirical Cumulated Distribution Function) or QQ-plots because those latter do not rely on bin-size!

Later, we will see two very important properties of the arithmetic average and of the mean that you will have to understand absolutely (the weighted average of deviations from the average and the average deviations from the average).

Remark

The "mode", denoted Mod or simply M_0, is defined as the value that appears most often in a set of data. In Microsoft® Excel® 11.8346, it is important to know that the `MODE( )` function returns the first value in the order of values having the largest number of occurrences therefore assuming a unimodal distribution.

D2. The "median", also named the "middle value", denoted M_e (or more simply denoted M when any confusion with something else is avoided...) of a set of numbers is the value separating the higher half from the lower half of a data sample, a population, or a probability distribution into two equal parts. In the case of a continuous statistical distribution $f(x)$ of a random variable X, it is the value that represents the value that has 50% of cumulative probability to occur (we will see further in details the concept of statistical distribution):

$$P(X \leq M_e) = P(X \geq M_e) = \int\limits_{-\infty}^{M_e} f(x)\mathrm{d}x = \int\limits_{M_e}^{+\infty} f(x)\mathrm{d}x = 0.5 = F(X) \tag{5.7.11}$$

In the case of a series of ordered values $x_1, x_2, \ldots, x_i, \ldots, x_n$, the median is therefore by definition the value such that we have the same number of values that are greater than or equal to it than the number of values that are less or equal to it.

Remarks

R1. The median is mainly used for skewed distributions, because it represent them better than the arithmetic average.

R2. The median is in practice often not a single value (at least in the case where n is even). Indeed, between the values corresponding to ranges $\dfrac{n}{2}$ and $\dfrac{n}{2}+1$ there is an infinite number of values to choose which cut the population in half. This is why for some people the median is not intuitive and especially when there are a lot of duplicates values. That's why in the case of duplicates, using in a spreadsheet software a formula like `=COUNTIF(range of cells,"<=Median)/COUNT(range of cells)` to calculate the proportion of cells having a value less than the median (or more than the median) and expecting a result of 50% is obviously wrong!

R3. Some corporations remove the duplicate values before calculating the Median. That's scientifically wrong but may be arguable in context of internal governance of the board committee (typically if evidence has shown that this lead to better decisions!).

More rigorously:

- If the number of terms is odd, i.e. of the form $2n+1$, the median of the series is the term of order $n+1$ (that the terms are all distinct or not!).
- If the number of terms is even, i.e. of the form $2n$, the median of the series is half-sum (arithmetic average) of the values of the terms of rank n and $n+1$ (that the terms are all distinct or not!).

$$\text{median}(x) = \begin{cases} x_{(n+1)/2}, & \text{if } n \text{ is odd} \\ \frac{1}{2}\left(x_{n/2} + x_{n/2+1}\right) & \text{if } n \text{ is even} \end{cases} \tag{5.7.12}$$

In any case, by this definition, it follows that there are at least 50% of the terms of the series that are smaller than or equal to the median, and at least 50% of the terms of the series that are greater than or equal to the median.

For example, consider the table of wages below:

Employee N°	Wage	Cumulated Employees	%Cumulated Employees
1	1,200	1	6%
2	1,220	2	12%
3	1,250	3	18%
4	1,300	4	24%
5	1,350	5	29%
6	1,450	6	35%
7	1,450	7	41%
8	1,560	8	47%
9	1,600	9	53%
10	1,800	10	59%
11	1,900	11	65%
12	2,150	12	71%
13	2,310	13	76%
14	2,610	14	82%
15	3,000	15	88%
16	3,400	16	94%
17	4,800	17	100%

Table 5.28: **Identification of the median**

There is in the table an odd number $2n + 1$ of values. So the median of the series is the term of rank $n + 1$. This is $1,600$.- (result that give any spreadsheet software). The arithmetic average is in this case about $2,020$.-.

As in so many cases, the simple explanation for the median from school is simple, but not actually true. The defitinion of a median is clear for odd vector lengths, but there are different options for even vector length. That's why the `R` software implements 9 of them and the default one, named "sample median" isn't at the days we write these lines compliant with results given by SAS, SPSS not even with its own `quantile()` function.

Indeed, the usual mathematical definition given first above is based on the inverse of the CDF, which gives the "left median", the lower end of the median interval. This also has the valuable property that the median is one of the observed data values - in the rare cases where you aren't interested in the median as an estimator, but just as a summary of all the data, it should certainly be a data value.

The problem with the left median is symmetry. Why not the right median? The inverse CDF gives you the left median because CDFs are right-continuous, but they could have been left-continuous; mathematicians just picked one possibility. So, the right median is another possibility. Or, you might want some compromise between the two, and that's one way to get the school median. But we've now got at least two answers and possibly three (if you count the right median).

In direct relation with the median it is important to define the following concept to understand the underlying mechanism:

D3. Be given a statistical series $x_1, x_2, \ldots, x_i, \ldots, x_n$, we name "dispersion of absolute differences" around x the number $\varepsilon'(x)$ defined by:

$$\varepsilon'(x) = \sum_i \mid x_i - x \mid \qquad (5.7.13)$$

$\varepsilon'(x)$ is minimum for a value of x closest to a given value x_i in the sense of the absolute error value. The median is the value that achieves this minimum (extremum)! The idea will then be to study the variations of the function to find the position of this extremum.

Indeed, we can write:

$$\forall x \in [x_r, x_{r+1}], r \in \{1, 2, 3, \ldots, n-1\} \quad \varepsilon'(x) = \sum_{i=1}^{r} \mid x_i - x \mid + \sum_{i=r+1}^{n} \mid x_i - x \mid \qquad (5.7.14)$$

Then by definition of the x value:

$$\begin{aligned}\varepsilon'(x) &= \sum_{i=1}^{r} \mid x_i - x \mid + \sum_{i=r+1}^{n} \mid x_i - x \mid \\ &= [rx - (x_1 + x_2 + \ldots + x_r) - [(x_{r+1} + \ldots + x_n - (n-r)x]] \\ &= (2r - n)x + (x_{r+1} + \ldots + x_n) - (x_1 + x_2 + \ldots + x_r)\end{aligned} \qquad (5.7.15)$$

What allows us to skip the absolute values is simply the choice of the index r that is taken so that the series of values in practice can always be split into two parts: all that is less than the element indexed by r and all that is superior to it (i.e.. the median by anticipation...).

$\varepsilon'(x)$ is also a piecewise (discrete) affine function (similar to the equation of a line for fixed values of r and n) where we see that by analogy the factor:

$$2r - n \qquad (5.7.16)$$

is the slope of the function and:

$$(x_{r+1} + \ldots + x_n) - (x_1 + x_2 + \ldots + x_r) \qquad (5.7.17)$$

the Y-intercept (ordinates at the origin).

The function is decreasing (negative slope) until r is less than $\dfrac{n}{2}$ and increasing when r is greater than $\dfrac{n}{2}$ (it passes trough an extremum!). Specifically, we distinguish two particularly cases of interest since n is an integer:

- If n is even, we can say that $n = 2n'$, then the slope can be written $2(r - n')$ and it is equal to zero if $r = n$ and then, as the result is valid by construction only for $\forall x \in [x_r, x_{r+1}]$ then $\varepsilon'(x)$ is constant on $[x_{n'}, x_{n'+1}]$ and we have an extremum necessarily in the middle of this range (arithmetic average of the two terms).

- If n is odd, we can say that $n = 2n' + 1$ (we cut the series into two equal parts), then the slope can be written $(2r - 2n' - 1)$ and it is zero if $r = n' + \dfrac{1}{2}$, as the result is only valid for $\forall x \in [x_r, x_{r+1}]$ then it is immediate that the middle value is the median $x_{n'+1}$.

We find out the median in both cases. We will also see later how the median is defined for a continuous random variable (the underlying idea is the same).

There is another practical case where the statistician has at its disposal only the values grouped in intervals of statistical classes. The procedure for determining the median is then different:

When we have at our disposal only a values grouped in intervals of statistical classes, the abscissa of the point of the median is generally within a class. To then get a more accurate value of the median, we perform a linear interpolation. This is what we name the "linear interpolation method of the median".

The median value can be read from the graph or calculated analytically. Indeed, consider the graph of the cumulative probability $F(x)$ in class intervals as below where the bounds of the intervals were connected by straight lines:

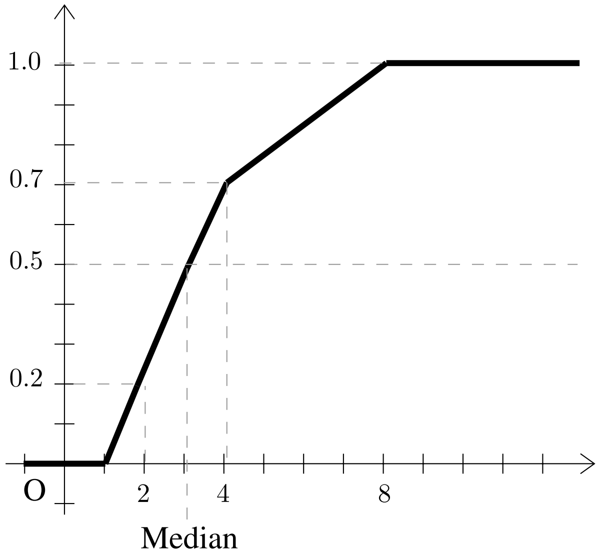

Figure 5.104: Graphical representation of the estimation of the median by linear interpolation

The value of the median M_e is obviously located at the crossroads between the cumulated probability of 50% (0.5) and the abscissa. Thus, by applying the basics of functional analysis, we have (just by observing that the slope in the interval containing the median is equal in the half-interval to the left and to right adjacent to the median):

$$\frac{\Delta x}{\Delta y} = \frac{M_e - 2}{0.5 - 0.2} = \frac{4 - 2}{0.7 - 0.2} \tag{5.7.18}$$

What we frequently write:

$$\frac{M_e - a}{0.5 - F(a)} = \frac{b - a}{F(b) - F(a)} \tag{5.7.19}$$

Thus the value of the median:

$$M_e = a + (b-a)\frac{0.5 - F(a)}{F(b) - F(a)} \tag{5.7.20}$$

Consider the following table that we will see again much later in this chapter:

Price of tickets	**Number of tickets**	**Cumulated number of tickets**	**Relative frequencies of tickets**
[0,50[	668	668	0.068
[50,100[	919	1,587	0.1587
[100,150[	1,498	3,085	0.3085
[150,200[	1,915	5,000	0.5000
[200,250[	1,915	6,915	0.6915
[250,300[	1,498	8,413	0.8413
[300,350[	919	9,332	0.9332
[350,400[	440	9,772	0.9772
[400 and +	228	10,000	1

Table 5.29: **Identification of the median and the mode**

We see that the "median class" is in the range $[150, 200]$ because the cumulative value of 0.5 is there (column at the right of the table) but the median has, using the previously established relation, the precise value of (it is trivial in the particular example of the table above, but we still do the calculation...):

$$M_e = 150 + (200-150)\frac{0.5 - 0.3805}{0.5 - 0.3805} = 200 \tag{5.7.21}$$

and of course we can do the same with any other percentile!

Definition (#5.7.121): We can also give on the way a definition to determine the "modal value" (the value that occurs the most frequently) often denoted:

$$M_0 = \text{mode}(X) = \arg\max_x f_X(x) \tag{5.7.22}$$

if we are only in possession of the frequencies of class intervals. To see that we start with diagram below named "grouped distribution" in frequencies bar:

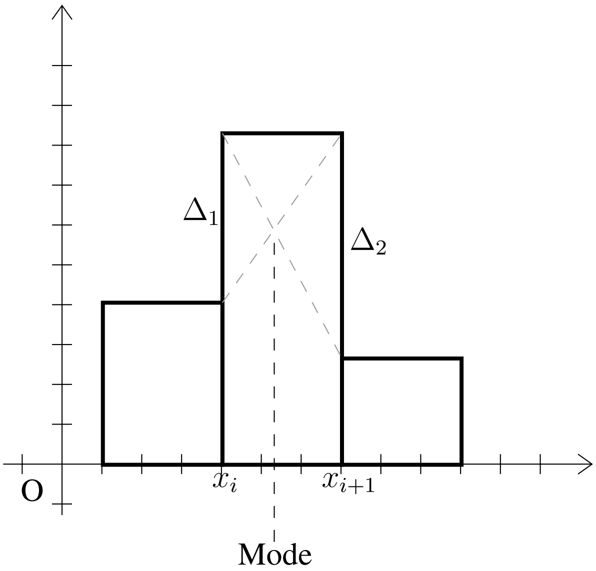

Figure 5.105: **Graphical representation of the estimation of the modal value with classes intervals**

Using the Thales relations (see section Euclidean Geometry 2610), it comes immediately, noting M_0 the modal value:

$$\frac{M_0 - x_i}{\Delta_1} = \frac{x_{i+1} - M_0}{\Delta_2} \tag{5.7.23}$$

As in a proportion, we do not change the value of the ratio by adding the numerators and adding the denominators, we get:

$$\frac{M_0 - x_i}{\Delta_1} = \frac{x_{i+1} - M_0}{\Delta_2} = \frac{x_{i+1} - x_i}{\Delta_1 + \Delta_2} \tag{5.7.24}$$

We then have:

$$M_0 = x_i + \frac{\Delta_1}{\Delta_1 + \Delta_2}(x_{i+1} - x_i) \tag{5.7.25}$$

With the previous example this gives then:

$$\begin{aligned} M_0 &= 150 + \frac{(1,915 - 1,498)}{(1,915 - 1,498) + (1,915 - 1,498)}(250 - 150) \\ &= 150 + \frac{1}{2}(250 - 150) = 150 + \frac{1}{2}100 = 200 \end{aligned} \tag{5.7.26}$$

The question that then arises is to the appropriateness of the choice of the mean, mode or median in terms of communication ... (normally we communicate them all three in corporate reports!).

A good example is that of the labour market where in general, while the average wage and the median wage are quite different, the institutions of state statistics calculate the median than many traditional media then explicitly equate to he concept of "arithmetic average" in their news...

Remark

To avoid getting an arithmetic average having little sense, we often calculate a "trimmed average", i.e. an arithmetic average calculated after removing outliers in the series (using Grubbs or Dixon tests or other some naive methods). See the section of Numerical Methods page 6560 for more details on this naive method.

The "quantile" generalize the concept of "median" by cutting the distribution in sets of equal parts (of the same cardinality we might say ...) or in other words in regular intervals. We define the "quartiles", the "decile" and "percentile" on the population, ordered in ascending order, that we divide by 4, 10 or 100 parts of the same size. So we talk about the 90th percentile to indicate the value separating the first 90% of the population and the 10% remaining.

Let X be a random variable with cumulated distribution function $F(x)$. The τth quantile of X is defined by:

$$Q_Y(\tau)\equiv\inf_x\{x:F(x)\geq\tau\} \tag{5.7.27}$$

or also sometimes denoted:

$$Q_X(p)=\min\{x\in\mathbb{R}\mid F_X(x)=p\} \tag{5.7.28}$$

The "midhinge" is the average of the first and third quartiles and is thus a measure of location. Equivalently, it is the 25% trimmed mid-range or 25% midsummary; it is an L-estimator (see page 1156) defined explicitly by:

$$\text{MH}(X)=\overline{Q_{1,3}(X)}=\dfrac{Q_1(X)+Q_3(X)}{2}=\dfrac{P_{25}(X)+P_{75}(X)}{2}=M_{25}(X) \tag{5.7.29}$$

The midhinge is related to the interquartile range (IQR), the difference of the third and first quartiles (i.e. $IQR=Q_3-Q_1$), which is a measure of statistical dispersion. The two are complementary in sense that if one knows the midhinge and the IQR, one can find the first and third quartiles.

The use of the term "hinge" for the lower or upper quartiles derives from John Tukey's work on exploratory data analysis in the late 1970 s, and "midhinge" is a fairly modern term dating from around that time. The midhinge is slightly simpler to calculate than the "trimean" (TM), which originated in the same context and equals the average of the median $\left(\tilde{X}=Q_2=P_{50}\right)$ and the midhinge:

$$\text{MH}(X)=2\,\text{TM}(X)-\text{med}(X)=2\dfrac{Q_1+2Q_2+Q_3}{4}-Q_2 \tag{5.7.30}$$

Definition (#5.7.122): The "P-th percentile" ($0<P\leq 100$) of a list of N ordered values (sorted from least to greatest) is the smallest value in the list such that no more than P percent of the data is strictly less than the value and at least P percent of the data is less than or equal to that value. This is obtained by first calculating the ordinal rank and then taking the value from the ordered list that corresponds to that rank. The ordinal rank n is calculated using the relation (using the round to nearest lower integer notation):

$$n=\left\lfloor\dfrac{P}{100}\cdot N\right\rfloor \tag{5.7.31}$$

Note that in Microsoft® Excel® 11.8346 the functions `QUARTILE( )`, `PERCENTILE( )`, `MEDIAN( )`, `PERCENTRANK( )` are available and it can be useful that we specify that there are several variants (at least nine as detailed in the excellent paper [271] and that are all available with the function `quantile( )` of the `R` statistical software!) of calculating these percentiles that explains possible variation between the results of different spreadsheet and statistical softwares[31]. When publishing scientific papers, scientists and engineers should always specify which on the nine methods of computing the quantiles was used!

✍**Example:**

The most famous example is to take the median for a better understanding of the vocabulary related to this topic! The median is indeed also the second quartile ($2\cdot 25\%$), but it's also at the same time the 0.5 quantile and the 50% percentile (i.e. centile) and the 5th decile.

More technically in the `R` software the 9 different types of quantile are defined as weighted averages of consecutive order statistics:

$$Q_i(p)=(1-\gamma)x_j+\gamma x_{j+1} \tag{5.7.32}$$

where $1\leq i\leq 9$, $\frac{j-m}{n}\leq p<\frac{j-m+1}{n}$, x_j is the jth order statistic, n is the sample size, the value of γ Is a function of $j=\lfloor np+m\rfloor$ and $g=np+m-j$, and m is a constant determined by the sample quantile type[32].

Remark

About Microsoft® Excel®... and it's conditional formatting tool... his user must not confuse the option "percentile" that is based on row numbers on the sorted values of interest on that of "percentage" defined for a vector $\vec{X}$ of values by:

$$\text{Percentage}(x_i)=\frac{x_i-\min\vec{X}}{R_{\vec{X}}}=\frac{x_i-\min\vec{X}}{\max\vec{X}-\min\vec{X}} \tag{5.7.33}$$

This concept is very important in the context of confidence intervals that we will see much further in this section and very useful in the field of quality with the use of "box plots" (also named "Box & Whiskers plots") to compare ("discriminate" as experts say) quickly two populations of data or more and especially to eliminate outliers (taking as reference the median will just make more sense!):

---

[31] The `R` Statistical software for example include all nine methods through a parameter of it's function `quantile()`.

[32] Based on the definitions, type = 1,3,4 should always give the same result for probs = 0.5 (i.e. median), and type = 2,5,6,7,8,9 should always give the same result for probs = 0.5 (i.e. median).

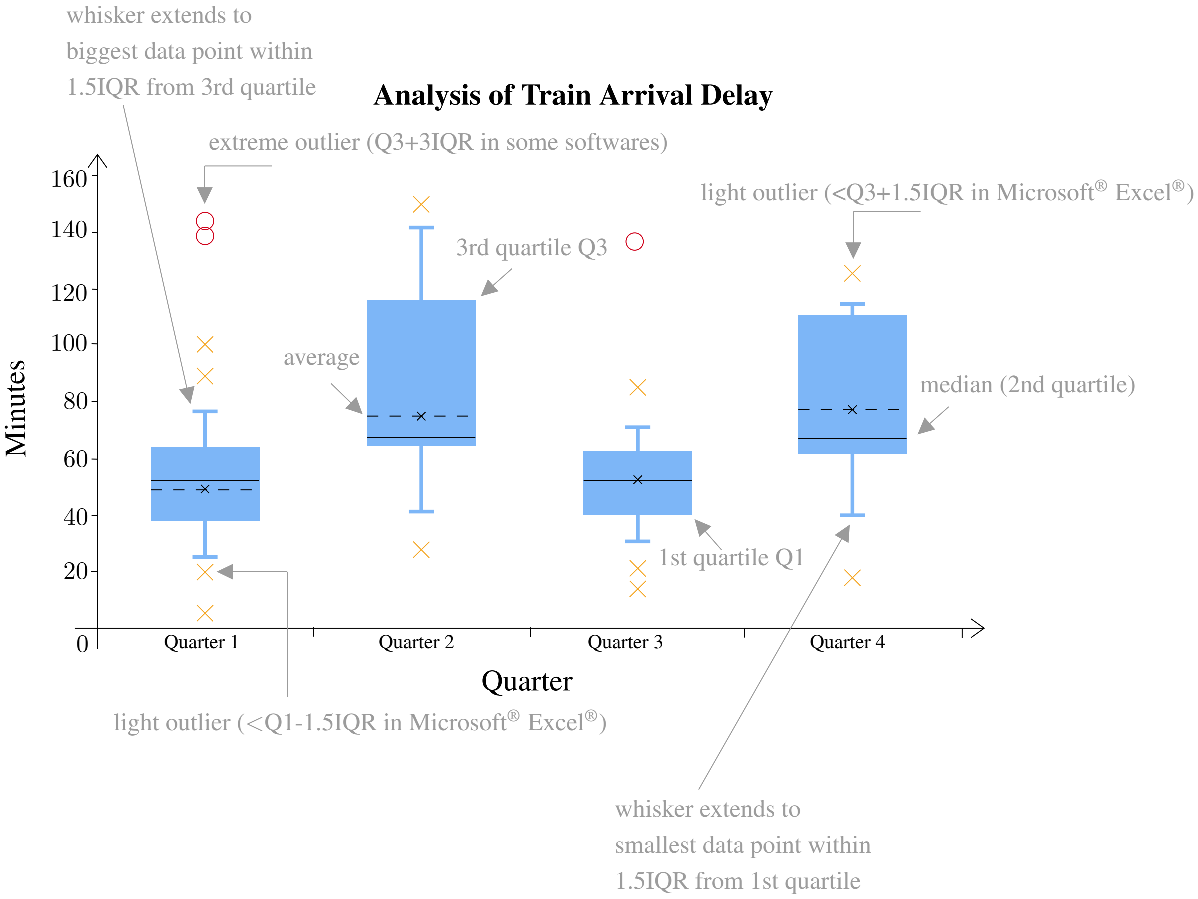

Figure 5.106: Box & Whiskers plot ideal chart type

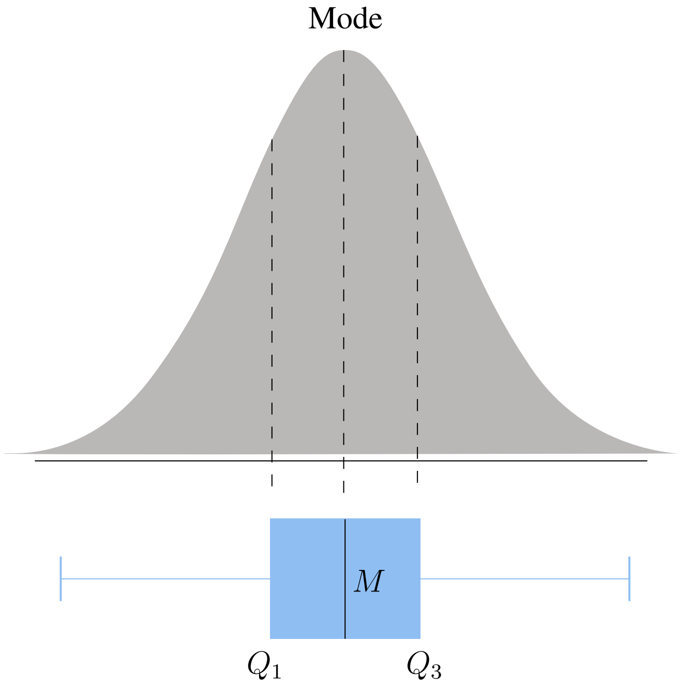
Another very important mental representation of box plots is the following (it can get an idea of the asymmetry of the distribution as is able to do the R software):



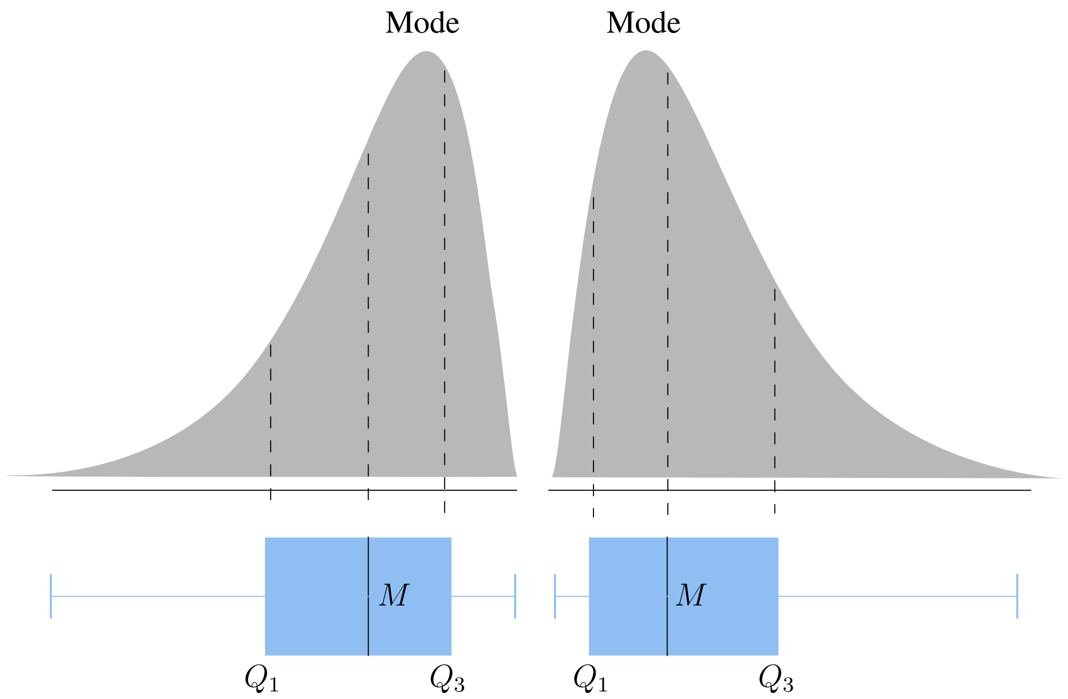


Figure 5.107: **Graphical representation of the mode, median and 1st + 3rd quartile compared to a distribution**

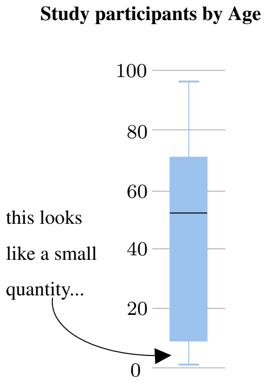
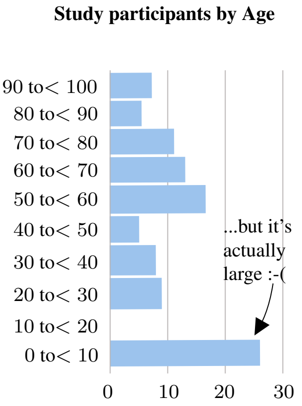
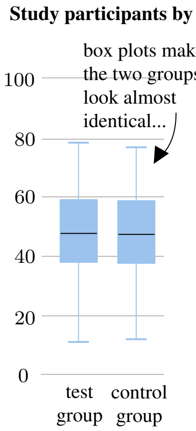
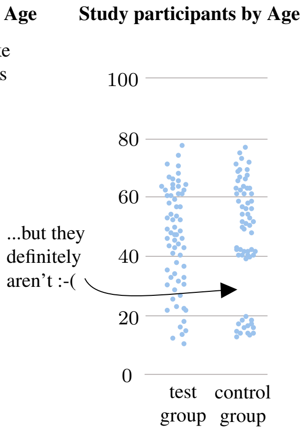
However notice that Box & Whiskers plots have important issues as depicted below:

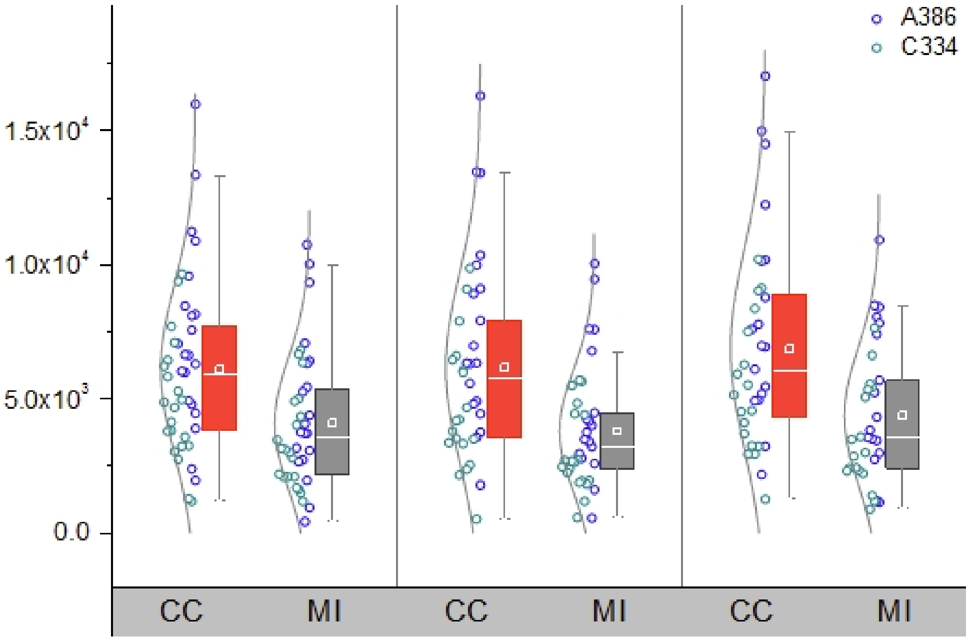








That's why we prefer in practice to use pirate plots (that are a mixed of violin plots and Box & Whiskers plots):



Remark

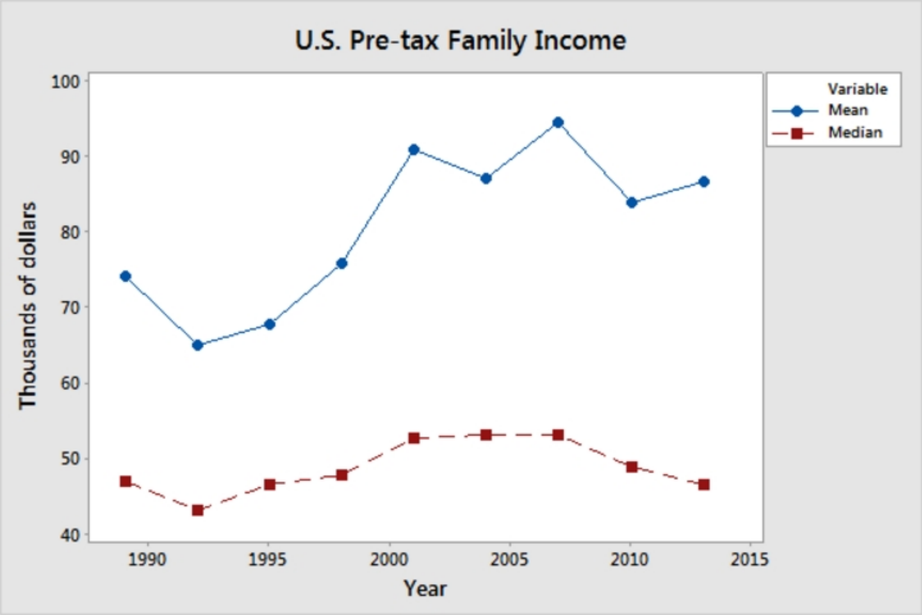
As we will prove it during our study of Inverse Transform Sampling in the section of Numerical Methods (see page 6710), the percentiles of any distribution are always uniformly distributed.

The concepts of median, outliers and confidence intervals that have yet been proved and/or just defined are so significant that there exists international standards for their proper use. First let us cite the norm ISO 16269-7:2001 *Median - Estimation and confidence intervals* and also the norm ISO 16269-4:2010 *Detection and treatment of outliers*. For more details and more outliers detection tests the reader can take a look to an entire textbook dedicated to outliers identification as [237] or look at the Data Science mind map (see page 6770) where more than twenty different tests are classified.

A beautiful demonstration on how governments can make statistics lie (hopefully now most of them has to give the data to the population for free) is for example the USA Federal Reserve that pointed out the fact a growth in average income since the 12010s (holocene calendar). But when we have access to the raw data:

`https://www.federalreserve.gov/econres/scfindex.htm`

and plot the median versus the average with for example Minitab 17 we get (the years in the plot are based on the Gregorian calendar):



and after some analysis you can point out that the increase in the average is largely due to increases in the highest 10% of incomes. The decline in the median at the same time suggests that typical Americans are in reality not doing as well since 12010 (holocene calendar)... Q.E.D!

Remark

Be careful with obvious conclusions when analyzing trends! As we will see during our study of Simpson's paradox (see further below page 967), when a body of data displays one trend, yet when broken (i.e. stratified) into subgroups, the opposite trend may appear into view for each of those subgroups!

D4. By analogy with the median, we define the "medial" as the value (in ascending order of values) that shares the (cumulative) sum values into two equal masses (i.e. the total sum divided by two).

In the case of our wages example, while the median gives the 50% of the salaries being below and above the medial gives how many employees share (and therefore the sharing wage) the first half and how many employees share the second half of the total of the wages costs.

For example, to return to our table on wages:

Employee N°	Wage	Cumulated Wages	% Cumulated Wages
1	1,200	1,200	3.5%
2	1,220	2,420	7%
3	1,250	3,670	10.7%
4	1,300	4,970	14.5%
5	1,350	6,320	18.4%
6	1,450	7,770	22.6%
7	1,450	9,220	26.8%
8	1,560	10,780	31.4%
9	1,600	12,380	36.1%
10	1,800	14,180	41.3%
11	1,900	16,080	46.8%
12	2,150	18,230	53.1%
13	2,310	20,540	59.8%
14	2,610	23,140	67.4%
15	3,000	26,140	76.1%
16	3,400	29,540	86%
17	4,800	34,340	100%

Table 5.30: **Identification of the mediale**

The sum of all wages is equal to $34,340$ and therefore the medial is $17,170$ then the medial is between the employees No. 11 and 12, while the median was $1,600$. We see then that the medial corresponds to 50% of the aggregate. This is a very useful indicator in Pareto or Lorenz analysis (see section Quantitative Management page 8095).

D5. Like the median, the "pseudomedian", used in some nonparametric statistical tests, is a measure of centrality for a dataset. The pseudomedian is derived by taking the median of the set of the means of pairs of data points, where the first is less than or equal to the second.

So, if the data were $\{1,3,7\}$, the pseudomedian would be the median of $\{$ mean $(1,1)$, mean $(1,3)$, mean $(1,7)$, mean $(3,3)$, mean $(3,7)$, mean $(7,7)\}$, which is 3.5. More technically, if the data are $x_1,x_2,\ldots,x_n$, then their pseudomedian is given by taking the median of the collection of $\frac{n}{2}(n+1)$ values of the form $w=\frac{x_i+x_j}{2}$ for $1\leq i\leq j\leq n$.

D6. The "root mean square" sometimes denoted simply Q which comes from the general relation:

$$\boxed{\mu_q=\sqrt[m]{\sum_{i=1}^{n}\frac{x_i^m}{n}}} \tag{5.7.34}$$

but where we take $m=2$.

Remark

It is one of the best known averages in statistics because the standard deviation is a root mean square (see below)!

✍**Example:**

Consider a square of side a, and another square of side b. The average area of two squares equals one square of side:

$$\mu_q^2=\frac{a^2+b^2}{2}\Rightarrow\mu_q=\sqrt{\frac{a^2+b^2}{2}} \tag{5.7.35}$$

In Microsoft® Excel® 11.8346 you can combine the functions `SUMSQ( )`, `COUNT( )` and to quickly calculate the root mean square as following:

```
=(SUMSQ(...)/COUNT(...))^(1/COUNT(...))
```

D7. The "harmonic mean" sometimes simply denoted H is defined by:

$$\boxed{\frac{1}{\mu_h}=\frac{\sum\limits_{i=1}^{n}x_i^{-1}}{n}} \tag{5.7.36}$$

It is little known but is often the result of simple and relevant arguments (typically the equivalent resistance of an electrical circuit with several resistors in parallel). There is a `HARMEAN( )` function in Microsoft® Excel® 11.8346 to calculate it.

✍**Example:**

Consider a distance d travelled in one direction at the speed v_1 and in the other direction (or not) at the speed v_2. The arithmetic average speed will be obtained by dividing the total distance $2d$ by the time of the travel:

$$v=\frac{2d}{t} \tag{5.7.37}$$

If we calculate the time it takes when travel d with a speed v_i that is simply the quotient:

$$t_i=\frac{d}{v_i} \tag{5.7.38}$$

The total time is therefore:

$$t=\frac{2d}{v}=t_1+t_2=\frac{d}{v_1}+\frac{d}{v_2} \tag{5.7.39}$$

If the distance is not the same for the both velocities anyway each velocity remains the same this is why d disappears!

In other words: We use the harmonic mean when are given to us ratios. Let's see other important examples to illustrate this:

✍**Examples:**

E1. Three investments have a Price / Return ratio of respectively 104%, 106% and 109% (so we lost money in all three investments in this particular case!). Knowing that the price of the three investments was initially the same, we use the harmonic average:

$$\mu_{\mathrm{h}}=\frac{3}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}}\cong 106.29\% \tag{5.7.40}$$

While an arithmetic average would give about 106.33%. Which makes a big difference when we manage millions in cash!

Note on the way that the following development shows that the harmonic mean is a special case of the "weighted arithmetic mean":

$$\begin{aligned}\mu_{a,y}=\sum_i w_i x_i=&\frac{\frac{1}{104}}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}}104+\frac{\frac{1}{106}}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}}106+\frac{\frac{1}{109}}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}}\\=&\frac{1}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}}+\frac{1}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}+\frac{1}{109}+\frac{1}{106}+\frac{1}{109}}=\frac{3}{\frac{1}{104}+\frac{1}{106}+\frac{1}{109}}\end{aligned} \tag{5.7.41}$$

If all weights are equal-weighted then we fall back on the standard arithmetic average!

E2. Consider that an investor puts us a disposition 300.- each month to buy a given asset. The first month this asset is worth 9.- so we can buy 33.333 units of it, the second month the asset is worth 11.- so we can buy 27.27227 units of it, finally the last and the third month the asset is worth 4.- so we can buy 75 units of it. The question is, what is the average price of this asset in our portfolio? We then have:

$$\mu_{\mathrm{k}}=\frac{900}{33.333+27.2727+75}=\frac{900}{\frac{300}{9}+\frac{300}{11}+\frac{300}{4}}=\frac{3}{\frac{1}{9}+\frac{1}{11}+\frac{1}{4}}\cong 6.6369.\text{-} \tag{5.7.42}$$

E3. Alice can finish a task in 2 hours and Bob takes 3 hours to finish the same task, how long would it take them if they worked together?

Alice works therefore a rate of $1/2$ (in on hour she can do 50% of the task) and Bob therefore at a rate of $1/3$ (in one hour he can do $33.\bar{3}\%$ of the taks). Together they work therefore at a rate of:

$$\frac{1}{2}+\frac{1}{3}=\frac{5}{6}$$

So it would take them $6/5=1.2$ of an hour (72 minutes) to finish it if they worked together.

D8. The "geometric mean" sometimes simply denoted G is defined in the general case by:

$$\boxed{\mu_g = \sqrt[n]{\prod_{i=1}^{n} x_i}} \tag{5.7.43}$$

This average is often forgotten by undergraduate employees but famous it is famous in the field of finance (see section Economy page 7548) this is also why there is an `GEOMEAN()` function in Microsoft® Excel® 11.8346 to calculate it.

A geometric mean is often used when comparing different items – finding a single "figure of merit" for these items – when each item has multiple properties that have different numeric ranges. For example, the geometric mean can give a meaningful "average" to compare two companies which are each rated at 0 to 5 for their environmental sustainability, and are rated at 0 to 100 for their financial viability. If an arithmetic mean were used instead of a geometric mean, the financial viability is given more weight because its numeric range is larger so a small percentage change in the financial rating (e.g. going from 80 to 90) makes a much larger difference in the arithmetic mean than a large percentage change in environmental sustainability (e.g. going from 2 to 5). The use of a geometric mean "normalizes" the ranges being averaged, so that no range dominates the weighting, and a given percentage change in any of the properties has the same effect on the geometric mean. So, a 20% change in environmental sustainability from 4 to 4.8 has the same effect on the geometric mean as a 20% change in financial viability from 60 to 72.

Remark

In 12010 (holocene calendar), the geometric mean was introduced to compute the Human Development Index by United Nations Development Programme. Poor performance in any dimension is directly reflected in the geometric mean. That is to say, a low achievement in one dimension is not anymore linearly compensated for by high achievement in another dimension. The geometric mean reduces the level of substitutability between dimensions and at the same time ensures that a 1% decline in index of, say, life expectancy has the same impact on the HDI as a 1% decline in education or income index. Thus, as a basis for comparisons of achievements, this method is also more respectful of the intrinsic differences across the dimensions than a simple average.

As for zero values, it is impossible to calculate the geometric mean with negative numbers! However, there are several workarounds for this problem, all of which require that the negative values be converted or transformed to a meaningful positive equivalent value. Most often this problem arises when it is desired to calculate the geometric mean of a percent change in a population or a financial return, which includes negative numbers.

For example, to get the geometric mean of the values $+12\%, -8\%, 0\%$ and $+2\%$, instead of calculating the geometric mean of their decimal multiplier equivalents of $1.12, 0.92, 1$ and 1.02, to compute a geometric mean equal to 1.0125. Subtracting 1 from this value gives the geometric mean of $+1.25\%$ as a net rate of growth or in financial circles is named the "Compound Annual Growth Rate C.A.G.R."), often denoted:

$$\text{CAGR} = \left(\left(\frac{\text{EV}}{\text{BV}}\right)^{\frac{1}{n}} - 1\right) \cdot 100 \tag{5.7.44}$$

where EV is the Ending Value of the investment, BV the Beginning value of the investment and n the number of years involved.

✍**Example:**

Suppose that a bank offers an investment opportunity and plans for the first year an interest (this is absurd, but this is an example) with a rate $(X-Y)\%$ but for the second year with an interest rate $(X+Y)\%$. At the same time another bank provides a constant interest rate for two years: $X\%$. We will say a little bit to fast that this is the same... In fact the two investments do not have the same profitability!

In the first bank, a capital C_0 will give after the first year of interest:

$$(X-Y)\%\cdot C_0 \tag{5.7.45}$$

and the second year:

$$(X+Y)\%\left[(X-Y)\%\cdot C_0\right] \tag{5.7.46}$$

In the other bank we will have after one year:

$$X\%\cdot C_0 \tag{5.7.47}$$

and after the second year:

$$X\%(X\%\cdot C_0) \tag{5.7.48}$$

and so on...

As you can probably see it the placement will not be identical if $Y\neq 0$! $X\%$ is the not the arithmetic average of $(X-Y)\%$ and $(X+Y)\%$.

Now if we write:

$$r_1=(X+Y)\% \quad \text{and} \quad r_2=(X-Y)\% \tag{5.7.49}$$

What is in reality the average value of the global interest rate r?

After 2 years (for example), the capital is multiplied by $r_1\cdot r_2$. If an average exists it will be denoted by r and the capital will thus be multiplied by r^2. Then we have the relation:

$$r^2=r_1r_2\Leftrightarrow r=\sqrt{r_1r_2} \tag{5.7.50}$$

This is an example where we therefore see the geometric mean. Forgetting to use of the geometric mean a common mistake in companies where some employees calculate the arithmetic average rate of increase of a reference value.

The reader can notice for the fun that the discrete arithmetic mean, geometric mean and harmonic mean that we have introduce earlier above can be encompassed in the following general expression:

$$f^{-1}\left(\frac{f(x_1)+\ldots+f(x_2)}{n}\right) \tag{5.7.51}$$

D9. The "moving average" of order k, also named sometimes "rolling mean", is defined on a sequence $x_1,\ldots,x_i,\ldots,x_n$ of realizations by:

$$\boxed{\forall i\in[1\ldots n-k]:\ \text{MA}_{i+k}(k)=\frac{\sum\limits_{j=i}^{i+k-1}x_j}{k}} \tag{5.7.52}$$

The moving average is used particularly in economics, where it represents a trend of a series of values, where the number of points is equal to the total number of points of the series of values less the number that you specify for the period (for a detailed example see the section of Economy page 7919).

Remark

On some Internet pages and statistical softwares, the "rolling mean" of order k (must be an odd positive number greater than 2!) is defined for a sequence $x_1,\ldots,x_i,\ldots,x_n$ (with $n\geq k$) by:

$$\forall i\in[(k+1)/2\ldots n-(k+1)/2]:\ \text{RM}_i=\frac{\sum\limits_{j=i+(k+1)/2-1}^{i+(k+1)/2-1}x_j}{k} \tag{5.7.53}$$

A moving average in finance is calculated from the average of a stock price over a given period: each point of a moving average of 100 sessions is the average of 100 last current values. This curve, displayed simultaneously with the evolution of the curve of the values, smooths the daily changes in the value and gives the possibility to better see the trends.

The moving averages can be calculated for different time periods, which can generate short-term trends MMC (20 sessions according to the habits of the domain), medium (50-100 sessions) or long-term MML (over 100 sessions):

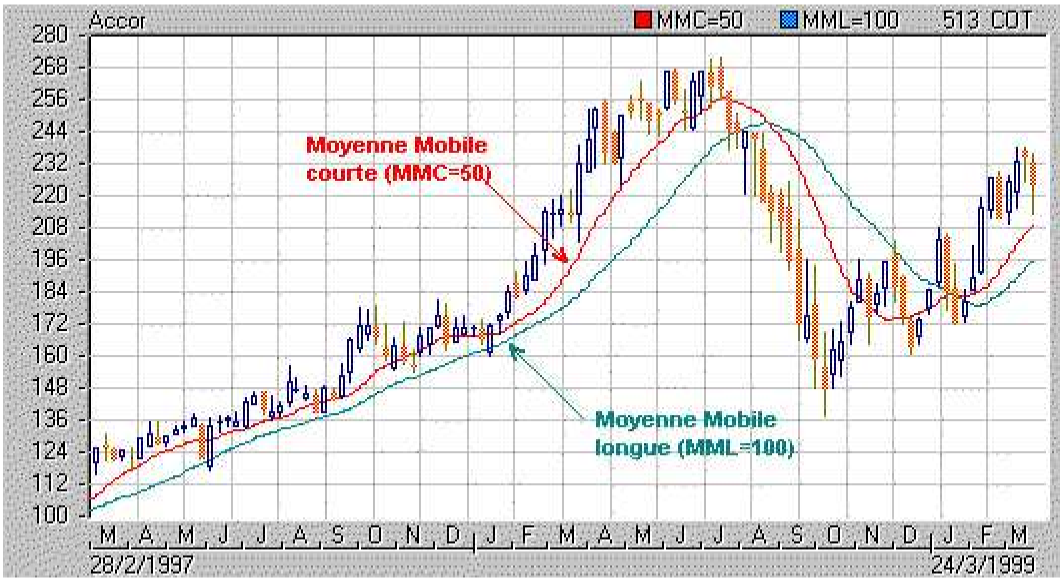


Figure 5.108: **Graphical representation of a few moving averages**

The crosses of the moving averages with the price curve (cutted with a certain granularity) of the value generate purchase or sale (basic) signals depending on the case:

- Buy signal: when the price curve crosses the MM up.
- Sell signal: when the price curve crosses the MM down.

In addition to the moving average, note that there are a lot of other artificial indicators often used in finance (the `R` software has a package dedicated only to such indicators). As for example the "upside/downside ratio".

The idea is the following: If you have a financial product (see section Economy page 7604) whose current price is P_c for which you have a goal of high gain corresponding to a high price, which we will denote by P_h (high price) and conversely, the potential loss that you feel is at a price P_l (low price).

Then the ratio:

$$\frac{P_h - P_c}{P_c - P_l} = \text{UD}_R \qquad (5.7.54)$$

gives the upside/down ratio!

✍**Examples:**

E1. For example, a financial product of 10.- with a low price of 5.- and a high price of 15.- has a ratio of $\text{UD}_R = 1$ and therefore an identical speculative factor to allow a gain or loss of 5.-.

E2. A financial product of 10.- with a low price of 5.- and a high price of 20.- has a ratio of $\text{UD}_R = 2$ and therefore twice the speculative potential gain compared to the loss.

Remark

Some financial institutions recommend to reject the UD_R below 3. Investors also tend to reject too high UD_R that can be a sign of artificial inflation.

D10. The "weighted average" (the moving average and arithmetic average are just a special cases of the weighted average with $w_i = 1$) is defined by:

$$\boxed{\mu_p = \frac{\sum\limits_{i=1}^{n} w_i x_i}{\sum\limits_{i=1}^{n} w_i}} \tag{5.7.55}$$

Is used for example in geometry to locate the centroid of a polygon, in physics to determine the center of gravity or in statistics to calculate the mean and other advanced regression techniques and in project management for estimating task durations forecast.

In the general case the weights w_i represents the weighted influence or arbitrary/empirical influence of the element x_i relatively to the others one.

D11. The "functional mean" or "integral average" is defined as:

$$\mu_f = \frac{1}{b-a}\int\limits_a^b f(x)\mathrm{d}x \tag{5.7.56}$$

where μ_f depends of a function f of a real integrated variable (see section Differential and Integral Calculus page 1497) on a range $[a, b]$. It is often used in signal theory (electronics, electrotechnichs).

5.7.2.1 Laplace Smoothing

To come back to our class frequencies seen above and before proceeding with the study of some mathematical properties of the averages... you should know that when we work with discrete probabilities distributions it happens very (very) often that we meet a typical problem whose source is the size of the population.

Consider as an example the case where we have 12 documents and that we would like estimate the probability of occurrence of the word "Viagra". We have on a sample the following values:

Document ID	Word occurrences
1	1
2	0
3	2
4	0
5	4
6	6
7	3
8	0
9	6
10	2
11	0
12	1

Table 5.31: **Class frequencies of the word**

Table that we can represent in another way:

Word occurrences	Documents	Probability
0	4	0.33
1	2	0.17
2	2	0.17
3	1	0.083
4	1	0.083
5	0	0
6	2	0.17

Table 5.32: **Respective frequencies classes of documents**

And here we have a common phenomenon. There is no record with 5 occurrences of the word of interest. The idea (very common in the field of Data Mining) is then to add artificially and empirically using a count using a technique named "Laplace smoothing" which involves adding k units at each occurrence. Therefore the table becomes:

Word occurrences	Documents	Probability
0	5	0.26
1	3	0.16
2	3	0.16
3	2	0.11
4	2	0.11
5	1	0.05
6	3	0.16

Table 5.33: **Frequencies classes of documents with smoothing**

Obviously this type of technique is debatable and beyond the scientific framework ... We even hesitated to introduce this technique in the section of Numerical Methods (with the rest of all the empirical numerical techniques) rather than here...

5.7.2.2 Means and Averages properties

Now we will see some relevant properties that connect some of these means and averages or are specific to a particular mean/average.

The first properties are important so beware to understand them:

P1. The calculation of the arithmetic, root mean square and harmonic average/mean can be generalized using the following expression:

$$\boxed{\mu=\sqrt[m]{\frac{1}{n}\sum_{i=1}^{n}x_i^m}} \tag{5.7.57}$$

where we see:

(a) For $m=1$, we get the arithmetic average

(b) For $m=2$, we get the root mean square

(c) For $m=-1$ we get the harmonic mean

P2. The arithmetic average has the property of linearity, that is to say (without proof because it is simple to check):

$$\boxed{\overline{\lambda x+\mu}=\lambda\bar{x}+\mu} \tag{5.7.58}$$

This is the statistical version of the property of the mean in the field of probabilities that we will see further.

P3. The weighted sum of the deviations from the arithmetic average is zero.

Proof 5.40.2. First, by definition, we know that:

$$n=\sum_{i=1}^{r}n_i \quad \text{and} \quad \mu=\frac{1}{n}\sum_{i=1}^{r}n_ix_i \tag{5.7.59}$$

then we have:

$$\boxed{\sum_{i=1}^{r} n_i(x_i-\mu)=\sum_{i=1}^{r} n_ix_i-\mu\sum_{i=1}^{r} n_i=\sum_{i=1}^{r} n_ix_i-\left(\frac{1}{n}\sum_{i=1}^{r} n_ix_i\right)n=\sum_{i=1}^{r} n_ix_i-\sum_{i=1}^{r} n_ix_i=0} \tag{5.7.60}$$

Thus, this tool can not be used as a measure of dispersion!

By extension, the arithmetic average of the weighted deviations from the average is also equal to zero:

$$\frac{\sum\limits_{i=1}^{r} n_i(x_i-\mu)}{n}=0 \tag{5.7.61}$$

■ Q.E.D.

This result is quite important because it will further be useful for a better understanding of the concept of standard deviation and variance.

P4. Now we would like to prove that:

$$\mu_h < \mu_g < \mu_a < \mu_q \tag{5.7.62}$$

> **Remark**
>
> The comparisons between the above means/averages and the median or the weighted or moving averages does not make sense this is why we won't compare them.

Proof 5.40.3. First, we consider two non-zero real numbers x_1 and x_2 as $x_2 > x_1 > 0$ and then we write:

(a) The arithmetic average:

$$\mu_a=\frac{x_1+x_2}{2} \tag{5.7.63}$$

(b) The geometric mean:

$$\mu_g=\sqrt{x_1x_2} \tag{5.7.64}$$

(c) The harmonic mean:

$$\frac{1}{\mu_h}=\frac{\dfrac{1}{x_1}+\dfrac{1}{x_2}}{2}=\frac{\dfrac{x_2}{x_1x_2}+\dfrac{x_1}{x_2x_1}}{2}=\frac{x_1+x_2}{2x_1x_2}\Leftrightarrow \mu_h=\frac{2x_1x_2}{x_1+x_2} \tag{5.7.65}$$

(d) The root mean square:

$$\mu_q^2=\frac{x_1^2+x_2^2}{2} \tag{5.7.66}$$

We will start to prove that $\mu_g > \mu_h$ by contradiction by putting $\mu_g - \mu_h < 0$:

$$\begin{aligned}\mu_g - \mu_h = \sqrt{x_1x_2} - \frac{2x_1x_2}{x_1+x_2} &= \frac{\sqrt{x_1x_2}x_1 + \sqrt{x_1x_2}x_2 - 2x_1x_2}{x_1+x_2} < 0\\ &\Rightarrow \sqrt{x_1x_2}x_1 + \sqrt{x_1x_2}x_2 - 2x_1x_2 < 0\\ &\Rightarrow \sqrt{x_1x_2}x_1 + \sqrt{x_1x_2}x_2 < 2x_1x_2\\ &\Rightarrow \frac{\sqrt{x_1x_2}}{x_2} + \frac{\sqrt{x_1x_2}}{x_1} < 2\\ &\Rightarrow \sqrt{\frac{x_1}{x_2}} + \sqrt{\frac{x_2}{x_1}} < 2\end{aligned} \tag{5.7.67}$$

By convenience we will now put:

$$y = \sqrt{\frac{x_2}{x_1}} \tag{5.7.68}$$

and we know that $y > 1$. We therefore have:

$$\sqrt{\frac{x_1}{x_2}} + \sqrt{\frac{x_2}{x_1}} = \frac{1}{y} + y \tag{5.7.69}$$

and remember we search if it is possible that:

$$\sqrt{\frac{x_1}{x_2}} + \sqrt{\frac{x_2}{x_1}} < 2 \tag{5.7.70}$$

We can now easily check this statement from the following equivalences:

$$\sqrt{\frac{x_1}{x_2}} + \sqrt{\frac{x_2}{x_1}} = \frac{1}{y} + y = \frac{y^2+1}{y} < 2 \Leftrightarrow y^2 + 1 - 2y < 0 \Leftrightarrow (y-1)^2 < 0 \tag{5.7.71}$$

There is also a contradiction, and this validates our initial hypothesis:

$$\mu_g - \mu_h > 0 \Leftrightarrow \mu_g > \mu_h \tag{5.7.72}$$

Let see if $\mu_g > \mu_a$.

Under the hypothesis $x_2 > x_1 > 0$. We search now to prove that:

$$\frac{x_1+x_2}{2} > \sqrt{x_1x_2} \tag{5.7.73}$$

Now we have the following equivalences:

$$\frac{x_1+x_2}{2} > \sqrt{x_1x_2} \Leftrightarrow (x_1+x_2)^2 > 4x_1x_2 \Leftrightarrow x_1^2 + x_2^2 - 2x_1x_2 > 0 \Leftrightarrow (x_1-x_2)^2 > 0 \tag{5.7.74}$$

and the last expression is obviously correct because the square of a (real) number is always positive which verifies our initial hypothesis:

$$\mu_a - \mu_g > 0 \Leftrightarrow \mu_a > \mu_g \tag{5.7.75}$$

We will prove now that $\mu_q > \mu_a$ by contradiction by putting $\mu_q - \mu_a < 0$:

$$\begin{aligned}\mu_q-\mu_a&=\sqrt{\frac{x_1^2+x_2^2}{2}}-\frac{x_1+x_2}{2}\\&\Rightarrow\sqrt{\frac{x_1^2+x_2^2}{2}}-\frac{x_1+x_2}{2}<0\\&\Rightarrow\sqrt{\frac{x_1^2+x_2^2}{2}}<\frac{x_1+x_2}{2}\\&\Rightarrow\frac{x_1^2+x_2^2}{2}<\frac{x_1^2+2x_1x_2+x_2^2}{4}\\&\Rightarrow x_1^2+x_2^2<\frac{x_1^2+2x_1x_2+x_2^2}{2}\\&\Rightarrow x_1^2-2x_1x_2+x_2^2<0\\&\Rightarrow(x_1-x_2)^2<0\end{aligned} \tag{5.7.76}$$

But the square of a (real) number is always positive which verifies our initial hypothesis:

$$\mu_q-\mu_a>0\Leftrightarrow\mu_q>\mu_a \tag{5.7.77}$$

We then have:

$$\boxed{\mu_h<\mu_g<\mu_a<\mu_q} \tag{5.7.78}$$

■ Q.E.D.

Once these inequalities proved, we can then move on to a figure that we attribute to Archimedes to place three of these averages. The interest of this example is to show that there are some remarkable relations between statistics and geometry (coincidence??).

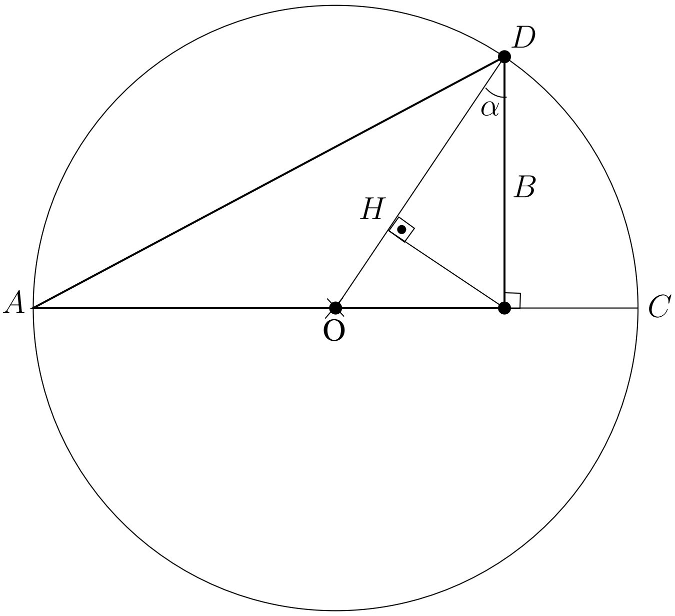

Figure 5.109: **Starting point for the geometric representation for the various averages**

We will first write $a = \overline{AB}, b = \overline{BC}$ and O is the midpoint of $\overline{AC}$. Thus, the circle is drawn with center O and radius $\overline{\text{O}A}$. D is the intersection of the perpendicular segment

$\overline{AC}$ through B and of the circle Ω (we can choose the intersection we want). H is itself the orthogonal projection of B on $\overline{\mathrm{O}D}$.

Archimedes says that $\overline{\mathrm{O}A}$ is the arithmetic average of a and b and that $\overline{BD}$ is the geometric mean of a and b, and $\overline{DH}$ is the harmonic mean of a and b.

We then prove that (could be trivial):

$$\overline{\mathrm{O}A}=\frac{\overline{AC}}{2}=\frac{a+b}{2} \tag{5.7.79}$$

Therefore $\overline{\mathrm{O}A}$ is the arithmetic average μ_a of a and b.

We have in the right-angled triangle ADB:

$$\overline{AD}^2=\overline{DB}^2+\overline{BA}^2 \tag{5.7.80}$$

Then we have in the right-angled triangle BDC:

$$\overline{DC}^2=\overline{BC}^2+\overline{DB}^2 \tag{5.7.81}$$

We then add these two relations, and we get:

$$2\overline{DB}^2+\overline{BA}^2+\overline{BC}^2=\overline{AD}^2+\overline{DC}^2 \tag{5.7.82}$$

We know that D is on a circle of diameter $\overline{AC}$, so ADC is rectangle on D. Therefore:

$$\overline{AD}^2+\overline{DC}^2=\overline{AC}^2 \tag{5.7.83}$$

And then we replace $\overline{BA}$ and $\overline{BC}$ by a and b:

$$2\overline{DB}^2+a^2+b^2=\overline{AC}^2=(a+b)^2\Leftrightarrow 2\overline{DB}^2=2ab \tag{5.7.84}$$

So finally:

$$DB=\sqrt{ab} \tag{5.7.85}$$

And therefore, $\overline{DB}$ is the geometric mean μ_g of a and b.

We have now to prove that $\overline{DH}$ is the harmonic mean of a and b. We have in a first time using the orthogonal projection as studied in the section of Vector Calculus (page 1821):

$$\overrightarrow{D\mathrm{O}}\circ\overrightarrow{DB}=\|\overrightarrow{D\mathrm{O}}\|\|\overrightarrow{DB}\|\cos(\alpha)=\overline{D\mathrm{O}}\cdot\overline{DH}=\frac{a+b}{2}\overline{DH} \tag{5.7.86}$$

Then we also have (again orthogonal projection):

$$\overrightarrow{D\mathrm{O}}\circ\overrightarrow{DB}=\left(\|\overrightarrow{D\mathrm{O}}\|\cos(\alpha)\right)\|\overrightarrow{DB}\|=\overline{DB}\cdot\overline{DB}=\overline{DB}^2 \tag{5.7.87}$$

Therefore we have:

$$\overline{DB}^2=\frac{a+b}{2}\overline{DH} \tag{5.7.88}$$

and since $DB=\sqrt{ab}$, we have then:

$$\overline{DH}=\frac{2ab}{a+b} \tag{5.7.89}$$

$\overline{DH}$ is therefore the harmonic mean of a and b. Archimedes was not wrong!

Definition (#5.7.123): In a contingency table (a table showing the distribution of one variable in rows and another in columns like the one visible below), the "marginal means" of one variable are the means for that variable averaged across every level of the other variable.

As the name implies, these means appear in the margins of the contingency table like the one below:

	Technique 1	**Technique 2**	**Technique 3**	*Marginal Mean*
Male	79.5	88.7	89.2	$(79.5+88.7+89.2)/3=85.8$
Female	88.3	87.7	90.6	$(88.3+87.7+90.6)/3=88.87$
Marginal Mean	$(79.5+88.3)/2=83.9$	$(88.7+87.7)/2=88.2$	$(89.2+90.6)/2=89.9$	

Table 5.34: **Marginal Mean example**

Marginal means are useful because they tell us the overall average value for a specific level of some variable. In essence, marginal means offer a simple way for us to understand the means for specific levels of variables.

Marginal means from descriptives like above are said to be "completely unconstrained", where as "estimated marginal means' are based on a model (like ANOVA, ANCOVA, etc.), and the assumptions of the model impose constraints on them. this is why they're named *estimated* marginal means, because they're estimated from a model!

Caution! Estimated marginal means are popular for summarizing linear models that include factors. For balanced experimental designs (see page 1007), they are just equal to the marginal means. For unbalanced data, they in essence estimate the marginal means you would have observed that the data arisen from a balanced experiment! Earlier developments regarding estimated marginal means were developed in a least-squares context and are sometimes referred to as "least-squares means". Since its early development, the concept has expanded far beyond least-squares settings!

5.7.2.2.1 Jensen Inequality

The "Jensen's inequality" is a particularly important relation (or property) in finance and insurance because it shows by the proof why an options seller will take the expected mean of payoff rather than payoff of the expect mean or why ultimately the insured will always pay more or equal than the differential of the expected mean of accident costs, and also in time series analysis why GARCH processes are naturally leptokurtic and also for the proof of the Kullback-Leibler divergence why that latter is strictly positive or null (see section Statistical Mechanics page 3542).

Theorem 5.41. Jensen's inequality will allow us to prove that for a convex function (see section Functional Analysis page 2280):

$$\boxed{f\left(\sum_{i=1}^{m} p_i x_i\right) \leq \sum_{i=1}^{m} p_i f(x_i)} \tag{5.7.90}$$

with $p_i > 0$, $\sum_i p_i = 1$. Either by using notations specific to the domain of statistics:

$$f(\mathrm{E}(X)) \leq \mathrm{E}(f(X)) \tag{5.7.91}$$

and to the valuation of options (see section Economy page 7788):

$$P(\mathrm{E}(S_T)) \leq \mathrm{E}(P(S_T)) \tag{5.7.92}$$

Before proceeding further, let us recall that a function f is concave if $-f$ is convex and vice versa. It is then immediate that:

$$f\left(\sum_{i=1}^{m} p_i x_i\right) \geq \sum_{i=1}^{m} p_i f(x_i) \tag{5.7.93}$$

Either by using notations specific to the domain of statistics:

$$f(\mathrm{E}(X)) \geq \mathrm{E}(f(X)) \tag{5.7.94}$$

Let's go to the proof and then we will make a small practical simplified example with derivatives in finance.

Proof 5.41.1. Let us see if:

$$f\left(\sum_{i=1}^{m} p_i x_i\right) \leq \sum_{i=1}^{m} p_i f(x_i) \tag{5.7.95}$$

is true by proceeding by induction. First for $m = 2$, we fall back on the classical definition of a convex function:

$$f(p_1x_1 + p_2x_2) \leq p_1 f(x_1) + p_2 f(x_2) \tag{5.7.96}$$

Or written differently as $p_1 + p_2 = 1$:

$$f(p_1x_1 + (1-p_1)x_2) \leq p_1 f(x_1) + (1-p_1) f(x_2) \tag{5.7.97}$$

Now, we assume the previous relation true for $m = n$, and we show that it is also true for $m = n + 1$:

$$f\left(\sum_{i=1}^{n+1} p_i x_i\right) = f\left(p_{n+1}x_{n+1} + \sum_{i=1}^{n} p_i x_i\right) = f\left(p_{n+1}x_{n+1} + (1-p_{n+1})\sum_{i=1}^{n} \frac{p_i}{1-p_{n+1}} x_i\right) \tag{5.7.98}$$

Since is f is convex, we can write:

$$f\left(p_{n+1}x_{n+1} + (1-p_{n+1})\sum_{i=1}^{n} \frac{p_i}{1-p_{n+1}} x_i\right) \leq p_{n+1} f(x_{n+1}) + (1-p_{n+1}) f\left(\sum_{i=1}^{n} \frac{p_i}{1-p_{n+1}} x_i\right) \tag{5.7.99}$$

Let us put:

$$q_i = \frac{p_i}{1-p_{n+1}} \tag{5.7.100}$$

for $i = 1 \ldots n$. We have $q_i > 0$ for all $i = 1 \ldots n$ and:

$$\sum_{i=1}^{n} q_i = \sum_{i=1}^{n} \frac{p_i}{1-p_{n+1}} = \frac{1}{1-p_{n+1}} \sum_{i=1}^{n} p_i = \frac{1-p_{n+1}}{1-p_{n+1}} = 1 \tag{5.7.101}$$

because for recall:

$$\sum_{i=1}^{n+1} p_i = 1 \tag{5.7.102}$$

and consequently:

$$\sum_{i=1}^{n} p_i = 1 - p_{n+1} \tag{5.7.103}$$

By hypothesis of recurrence we then have:

$$f\left(\sum_{i=1}^{n} q_i x_i\right) \leq \sum_{i=1}^{n} q_i f(x_i) \tag{5.7.104}$$

And therefore:

$$f\left(\sum_{i=1}^{n+1} p_i x_i\right) \leq p_{n+1} f(x_{n+1}) + (1-p_{n+1}) \sum_{i=1}^{n} \frac{p_i}{1-p_{n+1}} f(x_i) \tag{5.7.105}$$

by simplifying the expression on the right we get indeed:

$$f\left(\sum_{i=1}^{n+1} p_i x_i\right) \leq \sum_{i=1}^{n+1} p_i f(x_i) \tag{5.7.106}$$

■ Q.E.D.

✍**Example:**

We know that the payoffs of a Call and a Put are respectively at maturity (from the point of view of a buyer and therefore by symmetry from the point of view of a seller also in absolute value):

$$\begin{gathered} \max(S_T - K, 0) \\ \max(K - S_T, 0) \end{gathered} \tag{5.7.107}$$

Let us consider a price at maturity of 102.- and that the possible strikes at maturity are $\{100, 110, 150\}$, we have then have:

$$\begin{aligned} \mathrm{E}(P(S_T)) &= \frac{\max(x_{T,1} - K, 0) + \max(x_{T,2} - K, 0) + \max(x_{T,3} - K, 0)}{3} \\ &= \frac{\max(100 - 102, 0) + \max(110 - 102, 0) + \max(150 - 102, 0)}{3} = 18.\bar{6}.\text{-} \end{aligned} \tag{5.7.108}$$

and:

$$\begin{aligned}P(\mathrm{E}(S_T)) &= \max\left(\frac{x_{T,1}-K+x_{T,2}-K+x_{T,3}-K}{3},0\right)=\max\left(\frac{x_{T,1}+x_{T,2}+x_{T,3}-3K}{3},0\right)\\ &= \max\left(\frac{100+110+150-3\cdot 102}{3}\right)=\max(18,0)=18.\text{-}\end{aligned} \tag{5.7.109}$$

and so we have well for a Call from the point of view of a buyer or seller in absolute values:

$$P(\mathrm{E}(S_T))\leq \mathrm{E}(P(S_T)) \tag{5.7.110}$$

All what we have seen so far (and that we will see further!) is related to random values localized on a straight line. For statistics on a circle or a sphere, named "directional statistics", we strongly recommend the reader to look at [370].

5.7.3 Type of variables

In talking about variables quantitative or qualitative variables, sometimes you hear variables being described as categorical (or sometimes nominal), or ordinal, or interval. Below we will define these terms and explain why they are important.

Definitions (#5.7.124):

D1. The "discrete variables" (by counting) that belongs to $\mathbb{Z}$: Are analysed with statistical laws based on a countable definition domain always strictly positive (the Poisson or Hypergeoemetric distribution are such typical case in the industry). Are almost always represented graphically by histograms.

D2. The "continuous variables" (by measure) that belong to $\mathbb{R}$: Are analysed with statistical laws based on an uncountable domain of definition strictly positive or may take any positive or negative value (typically the Normal distribution in the industry). Are almost always represented graphically by histograms with class intervals.

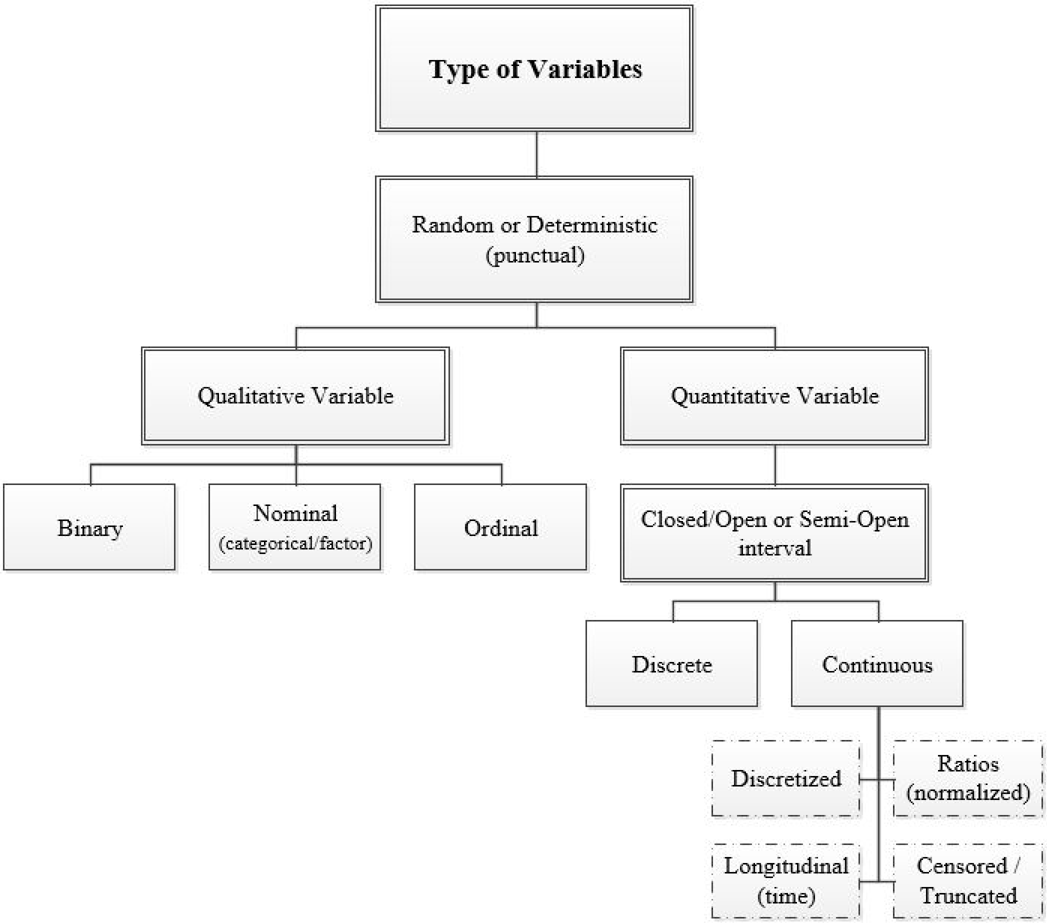
D3. The "attribute variables" (by classification): They are not digital data (only when they are coded with digits!) but qualitative data type {Yes, No}, {Passed, Failed}, {On time, Late}, {red, green blue, black}, etc. The binary data type attribute follow typically a Bernoulli or Binomial distribution while higher order qualitative variables have no average or standard deviation (indeed... try to calculate the mean and standard deviation between the qualitative variables Red, Green and Pink...).

In attribute variable we mainly distinct two subtypes of variables:

(a) A "categorical variable" (sometimes named a "nominal variable", or "multicategorical variable" or "polytomous variable") is one that has two or more categories, but there is no intrinsic ordering to the categories. For example, gender is a categorical variable having two categories (male and female) and there is no intrinsic ordering to the categories. Hair color is also a categorical variable having a number of categories (blonde, brown, brunette, red, etc.) and again, there is no agreed way to order these from highest to lowest. A purely categorical variable is one that simply allows you to assign categories but you cannot clearly order the variables. If the variable has a clear ordering, then that variable would be an ordinal variable, as described below.

(b) An "ordinal variable" is similar to a categorical variable. The difference between the two is that there is a clear ordering of the variables. For example, suppose you have a variable, named *economic status*, with three categories: {low, high, medium}. In addition to being able to classify people into these three categories, you can order the categories as low (1) $<$ medium (2) $<$ high (3). Now consider a variable like *educational experience* (with values such as: {high school graduate, college graduate, some college, elementary school graduate}). These also can be ordered as: elementary school graduate (1) $<$ high school graduate (2) $<$ some college (3) $<$ college graduate (4).

A pictorial and more complete summary of variable types in statistics is given in the figure below:



Type of Variables
Random or Deterministic (punctual)
Qualitative Variable
Quantitative Variable
Binary
Nominal (categorical/factor)
Ordinal
Closed/Open or Semi-Open interval
Discrete
Continuous
Discretized
Ratios (normalized)
Longitudinal (time)
Censored / Truncated

Figure 5.110: **Type of variables in statistics**

Remark

In principle, any continuous variable or any interval or ratio variable with more than two observed values is a polytomous variable, but the term is usually reserved for nominal and ordinal variables, named "unordered and ordered polytomous variables".

Understanding the different types of data is an important discipline for the engineers because it has important implications for the type of analysis tools and techniques that will be used.

A common question regarding the collection of data is what is the amount that should be collected. In fact it depends on the desired level of accuracy. We will see much further in this section (with proof!) how to mathematically determine the amount of data to collect.

Now that we are relatively familiar with the concept of average (mean), we can discuss on more formal calculations and that will make sense.

5.7.3.1 Discrete Variables and Moments

Consider X is an independent variable (an individual of a sample, whose property is independent of other individuals) that can take discrete random values (realizations of the vector $(X_1, X_2, \ldots, X_n)$) with respective probabilities $(p_1, p_2, \ldots, p_n)$ where, by the axioms of probabilities (see section Probabilities page 476):

$$p_i \in [0,1] \qquad \sum_i p_i = 1 \tag{5.7.111}$$

Let X be a numeric (quantitative) random variable (r.v.). It will be fully described in practice most of time by the value of the probability (for discrete variables) for a realization of this variable or by:

Definitions (#5.7.125):

D1. The probability corresponding to its value, named "probability density function[33]" (P.D.F.) and denoted by:

$$P(X) = f(X) \tag{5.7.112}$$

also sometimes (and more properly) denoted:

$$P(X = x) = f_X(x) \tag{5.7.113}$$

keeping in mind that $\sum f_X(x)$ must be equal to 1.

D2. The cumulative probability (for discrete AND continuous variables) to be typically less than or equal X for all realizations x. This "cumulative distribution function" (C.D.F.) is denoted by:

$$F(x) = P(x \leq X) \qquad \forall x \in \mathbb{R} \tag{5.7.114}$$

also sometimes (and more properly) denoted (for recall D is the domain of definition as defined on page 2211 in the section of Functional Analysis):

$$F_X(t) = P(X \leq t) = P(X \in]\min(D), t]) \qquad \forall t \in \mathbb{R} \tag{5.7.115}$$

with:

$$0 \leq P(X) \leq 1 \quad \text{and} \quad 0 \leq F(X) \leq 1 \tag{5.7.116}$$

where $F(x)$ is also named the "repartition function" of the random variable X. It is the theoretical proportion of the population whose value is less than or equal to x. It follows for example:

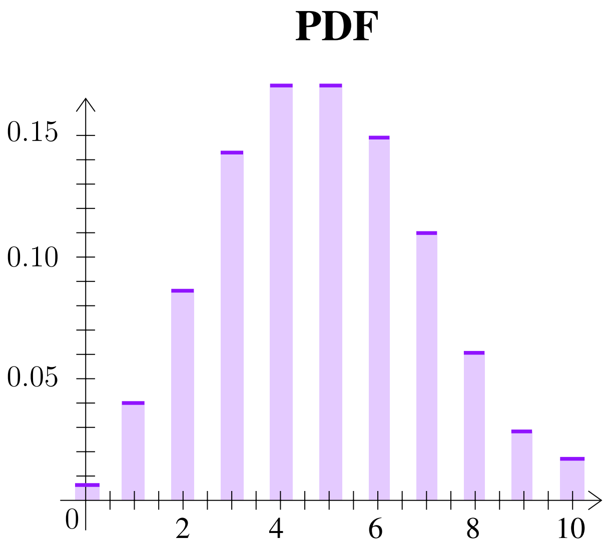
$$P(X > x) = 1 - F(x) \Leftrightarrow P(X \leq x) + P(X > x) = 1 \tag{5.7.117}$$

---

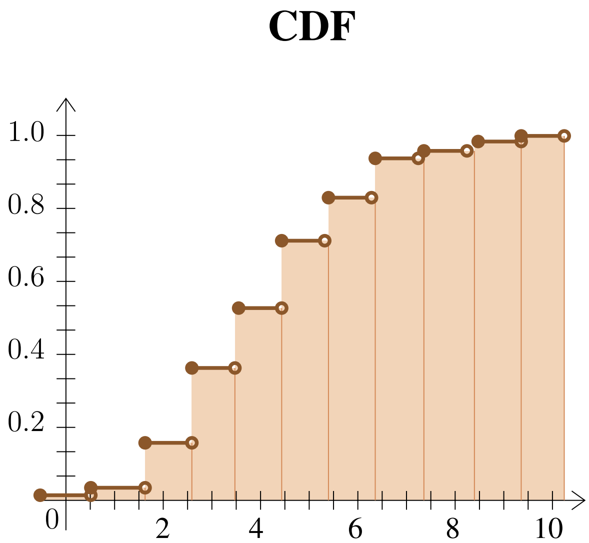
[33] For discrete variable some use instead the terminology: "probability mass function" (PMF).

More generally, for any two numbers a and b with $a < b$, we have:

$$P(a \leq x \leq b) = F(b) - F(a) \tag{5.7.118}$$



PDF



CDF

This definition obviously also applies to continuous variables!

D3. The "empirical cumulated distribution function" (E.C.D.F.) is naturally defined by (we have indicated the different notations that you can find in the literature):

$$\hat{F}(x) = \frac{1}{n}\sum_{i=1}^{n} 1_{x_i \leq x} = \frac{1}{n}\sum_{i=1}^{n} \delta_{x_i \leq x} = \frac{\#(i : x_i \leq x)}{n} \tag{5.7.119}$$

with $\hat{F}_n(x) \in [0,1]$ and associated with the sample of independent and identically distributed variables which as we know is named a "random vector" denoted by $\vec{X} = (x_1, x_2, \ldots, x_n)$.

It is simply the cumulative frequencies of appearance normalized to unity below a certain fixed value (approach that the majority of human beings are naturally using when seeking the repartition function).

So if we take again the example of wages already used above, then we have for example for x fixed to 1,800:

Ordered Wages $x_i \leq x$	**Frequencies** $1_{x_i \leq x}$
$1,200$	1
$1,220$	1
$1,250$	1
$1,300$	1
$1,350$	1
$1,450$	1
$1,450$	1
$1,560$	1
$1,600$	1
$1,800$	1
$1,900$	0
$2,150$	0
$2,310$	0
$2,600$	0
$3,000$	0
$3,400$	0
$4,800$	0

Table 5.35: **Example of the empirical repartition function**

And then:

$$\hat{F}_{17}(x \leq 1,800) = \frac{1}{17}\sum_{i=1}^{17} 1_{x_i \leq x} = \frac{1}{17} \cdot 10 \cong 59\% \tag{5.7.120}$$

The repartition function is clearly a monotonically increasing function (or more precisely "non-decreasing") whose values range from 0 to 1.

Let's look at a property that we will use several times and which is important in practice (property valid for both discrete and continuous random variables):

Let X be a random variable of repartition function F_X and density function f_X (let us recall that: $f_X = F'_X$) and $c^{te} \in \mathbb{R}^*$ a constant such that $y = c^{te}X$. We want to determine the repartition function and the density function of the random variable Y from F_X and f_X respectively.

By definition for $y \in \mathbb{R}$:

$$F_Y(y) = P(Y \leq y) = P\left(c^{te}X \leq y\right) = P\left(X \leq \frac{y}{c^{te}}\right) = F_X\left(\frac{y}{c^{te}}\right) \tag{5.7.121}$$

Therefore:

$$\forall y \in \mathbb{R} \quad F_Y(y) = F_X\left(\frac{y}{c}\right) \tag{5.7.122}$$

With regard to the density function we have:

$$f_Y(y) = F'_Y(y) = \frac{\mathrm{d}}{\mathrm{d}y}F_X\left(\frac{y}{c^{te}}\right) = \frac{1}{c^{te}}F'_X\left(\frac{y}{c^{te}}\right) = \frac{1}{c^{te}}f_X\left(\frac{y}{c^{te}}\right) \tag{5.7.123}$$

Therefore:

$$\forall y \in \mathbb{R} \quad f_Y(y) = \frac{1}{c^{te}}f_X\left(\frac{y}{c^{te}}\right) \tag{5.7.124}$$

5.7.3.1.1 Mean and Variance of Discrete Random Variables

Definition (#5.7.126): We define the "expectation" or "mean", also named "moment of order 1", of the random variable X by the relation (with various notations):

$$\boxed{\mu_X=\mathbb{E}(X)=\text{E}(X)=\sum_i P(X=x_i)x_i=\sum_i p_i x_i} \tag{5.7.125}$$

also sometimes named "parts rule".

In other words, we know that for every event in the sample space is associated with a probability that we also associate with a value (given by the random variable). The question then is to know what value we can get on the long term? The expected value (the mean...) is then the weighted average, by the probability, of all values of the events of sample space.

If the probability is given by a discrete distribution function $f(x_i)$ (see the definitions of distribution functions further below in the text) of the random variable, we then have:

$$p_i=f(x_i)\Rightarrow \mu_X=\text{E}(X)=\sum_i x_i f(x_i) \tag{5.7.126}$$

Remarks

R1. The mean μ_X can also be written just simply μ if there are no possible confusion on the random variable.

R2. If we consider each realization of the random variables $(x_1,x_2,\ldots,x_n)$ as the components of a vector $\vec{x}$ and each associated probability (or ponderation) $(p_1,p_2,\ldots,p_n)$ as the components of a vector $\vec{p}$ we can write the mean in a technical way using the scalar product (see section Vector Calculus page 1821) often written:

$$\vec{p}\circ\vec{x}=\langle\vec{p},\vec{x}\rangle=\sum_{i=1}^{n}p_i x_i=\text{E}(X) \tag{5.7.127}$$

Here are the most important mathematical properties of the mean for any random variable (whatever the distribution law!) and that we will often use throughout this section (and many other involving statistics):

P1. Multiplication by a constant (homogeneous):

$$\text{E}(\alpha X)=\sum_i \alpha x_i P(X=x_i)=\alpha\sum_i x_i P(X=x_i)=\alpha\text{E}(\alpha X) \tag{5.7.128}$$

P2. Sum of two random variables (independent or not!):

$$\begin{aligned}\mathrm{E}(X+Y) &= \sum_{i,j}\left[(x_i+y_j)P\left((X=x_i)\cap(Y=y_i)\right)\right]\\ &= \sum_{i,j}\left[x_iP\left((X=x_i)\cap(Y=y_j)\right)\right]+\sum_{i,j}\left[y_iP\left((X=x_i)\cap(Y=y_j)\right)\right]\\ &= \sum_i x_i\left[\sum_j P\left((X=x_i)\cap(Y=y_i)\right)\right]+\sum_j y_j\left[\sum_i P\left((X=x_i)\cap(Y=y_j)\right)\right]\\ &= \sum_i x_iP\left[(X=x_i)\cap\bigcup_j(Y=y_i)\right]+\sum_j y_jP\left[(Y=y_j)\cap\bigcup_i(X=x_i)\right]\\ &= \sum_i x_iP(X=x_i)+\sum_j y_jP(Y=y_j)=\mathrm{E}(X)+\mathrm{E}(Y)\end{aligned} \tag{5.7.129}$$

Where we used in the 4th line, the property view in the section of Probabilities (page 477):

$$P\left(\bigcup_{i\in\mathbb{N}}A_i\right)=\sum_{i\in\mathbb{N}}P(A_i) \tag{5.7.130}$$

We deduce that for n random variables X_i following any probability distribution:

$$\mathrm{E}\left(X_i\right)=\sum_i \mathrm{E}(X_i) \tag{5.7.131}$$

P3. Then mean of a constant a is equal to the constant itself:

$$\mathrm{E}(a)=\sum_i ap_i=a\sum_i p_i=a\cdot 1=a \tag{5.7.132}$$

P4. Mean of a product of two random variables:

$$\mathrm{E}(X\cdot Y)=\sum_{i,j}x_iy_iP(X=x_i,Y=y_j) \tag{5.7.133}$$

And if the two random variables are independent, then the probability is equal to the joint probability (see section Probabilities page 480). Therefore we have:

$$\begin{aligned}\mathrm{E}(X\cdot Y) &= \sum_{i,j}x_iy_jP(X=x_i,Y=y_j)=\sum_{i,j}x_iy_jP(x_i)P(y_j) \quad =\sum_{i,j}x_iP(x_i)y_iP(y_i)\\ &= \sum_{i,j}x_iP(x_i)\sum_{i,j}y_iP(y_i)=\mathrm{E}(X)\mathrm{E}(Y)\end{aligned} \tag{5.7.134}$$

✍**Example:**

For a unique dice the expected value is:

$$\text{E}(X)=\frac{1}{6}\cdot 1+\frac{1}{6}\cdot 2+\frac{1}{6}\cdot 3+\frac{1}{6}\cdot 4+\frac{1}{6}\cdot 5+\frac{1}{6}\cdot 6=\frac{1}{6}\cdot 21=3.5$$

Using the property of linearity of the mean, we have then for the sum of n dices:

$$\text{E}_n(X)=n\text{E}(X)=n\cdot 3.5$$

For the special case of two dices, there the most likely sum will be:

$$\text{E}_2(X)=2\text{E}(X)=2\cdot 3.5=7$$

So the mean of the product of independent random variables is always equal to the product of their means.

We will assume as obvious that these four properties extend to the continuous case!

Definition (#5.7.127): After having translated the trend by the mean it is interesting to have and indicator that reflects the dispersion or "dispersion" around the mean by a value named "variance of X" or "second-order centered moment" or "mean square error (MSE), written $\text{V}(X)$ or σ_X^2 (read "sigma square") and given in its discrete form by:

$$\boxed{\sigma_X^2=\text{V}(X)=\text{MSE}=\text{E}\left[(X-\mu_X)^2\right]=\sum_i (x_i-\mu_X)^2 f(x_i)=\sum_i (x_i-\mu_X)^2 p_i} \tag{5.7.135}$$

In other words the variance measure of how much a distribution of values is spread from the mean.

The variance is however not directly comparable to the mean because of the fact that the units of the variance are the square of the unit of the random variable, which follows directly from its definition. To have an indicator of dispersion that can be compared to the parameters of central tendency (mean, median and ... mode), it then suffices to take the square root of the variance.

For convenience, we define the "standard deviation" of X by:

$$\boxed{\sigma_x=\sigma(X)=\sqrt{\text{V}(X)}} \tag{5.7.136}$$

The standard deviation is therefore the root mean square of the deviations (or "mean squared difference") between the observations and their mean.

Remarks

R1. The standard deviation σ_X of the random variable X can be simply denoted σ if there is no possible confusion.

R2. The standard deviation and variance are, in the literature, often named "dispersion parameters" or "scale parameters" as opposed to the mean, mode and median that are named "positional parameters".

Notice that when two different types of measurement methods give different statistical distributions of the variable of interest, then in physics and statistics, the distance between the two peaks of some unimodal distributions is named the "tension". For example in the year 12021 (holocene calendar), the tension between the cosmological radio-wave background measurement method and the direct measurement method of the Hubble constant has a tension of 5σ as illustrated below:

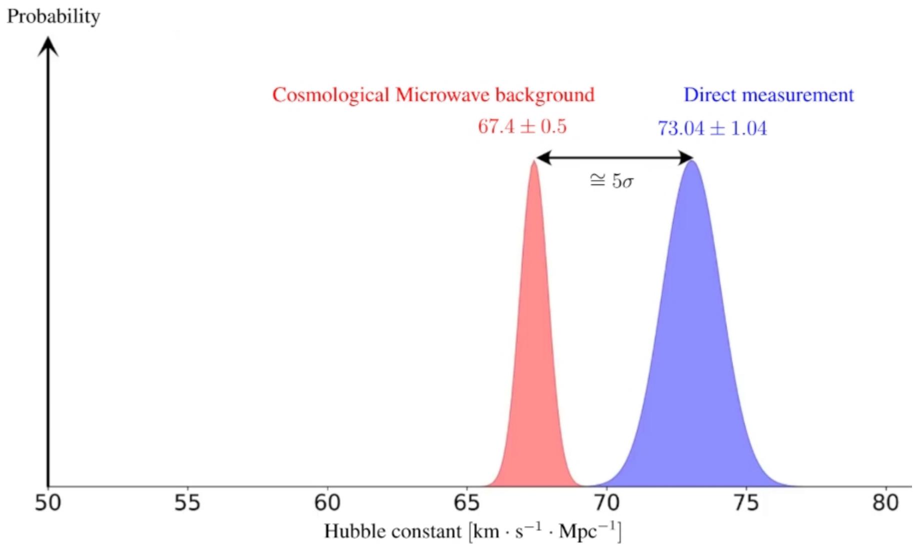


Figure 5.111: **Illustration of "tension" in statistics**

Definition (#5.7.128): The ratio (expressed in %):

$$\boxed{\mathrm{CV}=\frac{\sigma}{\mu}} \tag{5.7.137}$$

is often used in business to compare the mean and the standard deviation and is named the "coefficient of variation C.V." because it has no units (which is it's main advantage!) and because many industrial statistical methods consider that a good C.V should ideally be just about a few % only.

More generally for any statistics estimator $\hat{\theta}$ (sum, average, median, etc.) we can build a coefficient of variation such that:

$$\mathrm{CV}=\frac{\sigma_{\hat{\theta}}}{\hat{\theta}} \tag{5.7.138}$$

Thus, in practice we consider that:

Coefficient of variation	**Quality**
20%	Poor
10%	Acceptable
5%	Controlled
2.5%	Excellent
1.25%	World Class
0.0625%	Rarely achieved

Table 5.36: **Qualitative judgements of C.Vs commonly accepted**

Why do we find a square (respectively a square root) in the definition of the variance? The intuitive reason is simple (the rigorous much less ...). Remember, that we have shown above that the sum of the deviations from the actual weighted average is always zero:

$$\sum_{i=1}^{r} n_i(x_i - \mu) = 0 \tag{5.7.139}$$

If we assimilate the size of each sample by the probability by normalizing the sample size with respect to n, we come upon a relation that is the same as the variance with the difference that the term in brackets is not squared. And then we immediately see the problem... the dispersion measure is always zero, hence the need to bring this to the square.

We could, however, imagine to use the absolute value of deviations from the mean, but for a number of reasons that we will see later during our study of estimators, the choice of squaring is quite natural.

Note, however, the common use in the industry of two common other indicators of dispersion:

1. The "mean absolute deviation" (mean of the absolute values of deviations from the mean):

   $$\text{AVEDEV} = \frac{\sum\limits_{i=1}^{n} \mid x_i - \mu \mid}{n} \tag{5.7.140}$$

   Which is a very elementary indicator used when we do not want to make statistical inference on a series of measures. This deviation can be easily calculated in the English version of Microsoft® Excel® 11.8346 using the `AVEDEV( )` function.

2. The "median absolute deviation" denoted MAD (median of absolute values of deviations from the median):

   $$\text{MAD} = M_e\left(\mid X - M_e(X) \mid\right) \tag{5.7.141}$$

   which is considered as a more robust measure of dispersion than those given by the mean absolute deviation or the standard deviation (unfortunately this indicator is not natively integrated in spreadsheets softwares). That latter must not be confused with the "mean median absolute deviation" defined by:

   $$\text{MMAD} = \frac{\mid X - M_e(X) \mid}{n} \tag{5.7.142}$$

Remark

In order to use the MAD as a consistent estimator for the estimation of the standard deviation σ (see further below for the definition of the standard deviation) as we will need it for our study of Control Charts (see section of the corresponding name page 8934), one takes:

$$\hat{\sigma} = k \cdot \text{MAD} \tag{5.7.143}$$

where k is a constant scale factor, which depends on the distribution.

For normally distributed data as we will see during our study of the half-Normal distribution (see page 796) we take:

$$\text{MAD} \cong 2\sqrt{2}\text{erf}^{-1}(0.50) \cong 0.67499\sigma \tag{5.7.144}$$

Hence:

$$\sigma \cong 1.4826\text{MAD} \tag{5.7.145}$$

Having seen the definition of the both concepts let us see now through an example how to calculate them and their difference on a same set of data!

✍**Example:**

Consider the following measure of a random variable X:

$$(1, 1, 2, 2, 4, 6, 9) \tag{5.7.146}$$

and where the median value is given as we know by:

$$M_e(X) = M_e(1, 1, 2, 2, 4, 6, 9) = 2 \tag{5.7.147}$$

The absolute deviations from the median are then:

$$\mid X - M_e(x) \mid = (1, 1, 0, 0, 2, 4, 7) \tag{5.7.148}$$

Placed in ascending order, we then have:

$$(0, 0, 1, 1, 2, 4, 7) \tag{5.7.149}$$

where we easily identify the absolute deviation from the median, which is:

$$\text{MAD} = M_e(0, 0, 1, 1, 2, 4, 7) = 1 \tag{5.7.150}$$

In the case where we have at disposition a series of measures, we can estimate the experimental value of the mean (expectation) and of the variance with the following estimators (it is simply the of average and standard deviation of a sample when the events are equally likely) with the specific notation:

$$\boxed{\hat{\mu}=\sum_{i=1}^{n}x_i \quad \text{and} \quad \hat{\sigma}^2=\frac{1}{n}\sum_{i=1}^{n}(x_i-\hat{\mu})^2} \tag{5.7.151}$$

Proof 5.41.2. First for the mean:

$$\mu=\mathrm{E}(X)=\sum_{i=1}^{n}p_ix_i=\sum_{i=1}^{n}\frac{1}{n_i}x_i=\frac{1}{n}\sum_{i=1}^{n}x_i=\hat{\mu} \tag{5.7.152}$$

And for the variance:

$$\begin{aligned}\sigma^2&=\mathrm{E}((X-\mathrm{E}(X))^2)=\mathrm{E}((X-\hat{\mu})^2)=\sum_{i=1}^{n}p_i(x_i-\mu)^2=\sum_{i=1}^{n}\frac{1}{n_i}(x_i-\mu)^2\\&=\frac{1}{n}\sum_{i=1}^{n}(x_i-\hat{\mu})^2=\hat{\sigma}^2\end{aligned} \tag{5.7.153}$$

■ Q.E.D.

Theorem 5.42. Let us prove now a very nice little property as the arithmetic average is an optimum for the sum of squared errors.

Proof 5.42.1.

$$\sum_{i=1}^{n}(x_i-\alpha)^2=\sum_{i=1}^{n}x_i^2-2\alpha\sum_{i=1}^{n}x_i+n\alpha^2 \tag{5.7.154}$$

And if we search for α as the derivative of the above expression is equal to zero:

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\left(\sum_{i=1}^{n}x_i^2-2\alpha\sum_{i=1}^{n}x_i+n\alpha^2\right)=0 \tag{5.7.155}$$

then α is an optimum. We have therefore:

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\left(\sum_{i=1}^{n}x_i^2-2\alpha\sum_{i=1}^{n}x_i+n\alpha^2\right)=-2\sum_{i=1}^{n}x_i+2n\alpha=0 \tag{5.7.156}$$

or after rearrangement and an elementary simplification we get:

$$\alpha=\frac{1}{n}\sum_{i=1}^{n}x_i \tag{5.7.157}$$

■ Q.E.D.

It is effectively the arithmetic average! Now to see if it is a maximum extrema or minimum extrema we just need calculate the second derivative (see section Differential and Integral Calculus page 1454) and see if it gives a positive constant (i.e. the first derivative increases when α increase). Therefore we immediately see that it is effectively a minimum extrema!!!

Remark

The term of the sum that we see in the expression of the variance (standard deviation) is named the "sum of squared deviations from the mean" or "sum of squared errors from the mean". We also name it the "total sum of squares", or "total variation", or "sum of square errors" in the context of the study of the ANOVA (see the further below)

Before that we continue, let us recall the concept of geometric mean seen above (widely used for returns in finance or growth analyses in % of sales):

$$\mu_g=\sqrt[n]{\prod_{i=1}^{n} x_i}=\left(\prod_{i=1}^{n} x_i\right)^{\frac{1}{n}} \tag{5.7.158}$$

It's fine but employees in financial departments also need to calculate the standard deviation of this average. The idea is then to take the logarithm to reduce it to a simple arithmetic mean (it is still obviously an estimator!):

$$\ln(\mu_g)=\ln\left(\left(\prod_{i=1}^{n} x_i\right)^{\frac{1}{n}}\right)=\frac{1}{n}\ln\left(\left(\prod_{i=1}^{n} x_i\right)\right)=\frac{1}{n}\sum_{i=1}^{n}\ln(x_i) \tag{5.7.159}$$

Remark

For the section of Finance, if we denote the decimal multiplier equivalent $R_i=1+r_i$ or a random variable return r_i then:

$$\begin{aligned}\mu_a(\ln(R))&=\frac{1}{n}[\ln(R_1)+\ln(R_2)+\ldots+\ln(R_n)]=\frac{1}{n}\ln(R_1R_2\ldots R_n)=\ln\left[(R_1R_2\ldots R_n)^{1/n}\right]\\&=\ln\left(\sqrt[n]{R_1R_2\ldots R_n}\right)=\ln(\mu_g(R))\end{aligned} \tag{5.7.160}$$

However if $\mu_g(R)\cong 1$ then using first order Taylor expansion $\ln(x)\cong x-1$ (around $x\cong 1$ obviously!) we get:

$$\mu_a(\ln(R))=\ln(\mu_g(R))=\mu_g(R)-1 \tag{5.7.161}$$

So in other words: the arithmetic average of the log-returns (their decimal multiplier equivalent) is approximately equal to geometric mean of the returns (their decimal multiplier equivalent). It is an approximation you can often found in many financial computer codes.

Therefore, since taking the logarithm of the values we have the arithmetic mean of the log values, then the logarithm of the geometric standard deviation (with physicist reasoning like...) will be:

$$\ln\left(\hat{\sigma}_g\right)=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(\ln(x_i)-\ln(\mu_g))}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}\ln\left(\frac{x_i}{\mu_g}\right)} \tag{5.7.162}$$

Then we just take the exponential of the standard deviation of the logarithms of the values to have the "geometric standard deviation":

$$\hat{\sigma}_g=e^{\sqrt{\frac{1}{n}\sum_{i=1}^{n}\ln\left(\frac{x_i}{\mu_g}\right)}} \tag{5.7.163}$$

It can be easily proved, using the same method as earlier, that the geometric standard deviation of the returns (the last relation above) is approximately equal to the Pearson standard deviation of the log-returns.

By the way, remember that we have proved earlier that $\mu_g < \mu_a$.

The variance can also be written in the very important way named the "Huygens relation" or "König-Huygens theorem" or "Steiner translation theorem" that we will reuse several times thereafter. Let's see what it is:

$$\begin{aligned}\mathrm{V}(X)&=\mathrm{E}[(X-\mu_X)^2]=\sum_i(x_i-\mu_X)^2f(x_i)=\sum_i\left(x_i^2-2\mu_Xx_i+\mu_X^2\right)f(x_i)\\&=\sum_i x_i^2f(x_i)-2\mu_X\sum_i x_if(x_i)+\mu_X^2\sum_i f(x_i)=\sum_i x_i^2f(x_i)-2\mu_X^2+\mu_X^2\\&=\sum_i x_i^2f(x_i)-\mu_X^2=\mathrm{E}(X^2)-\mu_X^2=\mathrm{E}(X^2)-\mathrm{E}(X)^2\end{aligned} \tag{5.7.164}$$

Remark

The reader may found interesting to know that in many business applications of statistics (especially in "Machine Learning"), when the statistics must be updated "on the fly" each time new data appear we speak then of "data flow statistics" or "data stream mining" or even "online learning". So an efficient algorithmic way must be found to update the calculations without recalculating everything from scratch! The simplest typical example is the variance! Updating the sample variance calculation looks obviously quite consuming if we just add new data according to:

$$\hat{\sigma}=\sqrt{\sum_i\frac{1}{n}(x_i-\hat{\mu})^2} \tag{5.7.165}$$

But using the Huygens relation, we see that this sample variance becomes much less consuming to calculate as it becomes only a problem of updating two sums:

$$\hat{\sigma}=\sqrt{\mathrm{E}(X^2)-\mathrm{E}(X)^2}=\sqrt{\frac{\sum_i x_i^2}{n}-\frac{\left(\sum_i x_i\right)^2}{n}} \tag{5.7.166}$$

Let us now do a relatively small hook to a common scenario generator of errors in business when several statistical series are handled (very common case in the industry as well as in insurance or finance)!

Consider two data series on the same character:

- $(x_1,n_1),(x_2,n_2),\ldots,(x_p,n_p)$ sample of total size n, arithmetic average $\bar{x}$, standard deviation σ_x.
- $(y_1,m_1),(y_2,m_2),\ldots,(y_p,m_q)$ sample of total size m, arithmetic average $\bar{y}$, standard deviation σ_y.

with $n+m=N$.

We then have:

$$\bar{z}=\frac{\sum_{i=1}^{p} x_i+\sum_{i=1}^{q} y_i}{n+m}=\frac{n\frac{1}{n}\sum_{i=1}^{p} x_i+m\frac{1}{m}\sum_{i=1}^{q} y_i}{n+m}=\frac{n\bar{x}+m\bar{y}}{n+m} \tag{5.7.167}$$

So the average of the averages is not equal to the overall average (first common mistake in business) except if the two data series have the same sample size ($n=m={}^1\!/\!_2N$)!!!

Let have a look at the standard deviation always with the same situation. First remember that we have:

$$\begin{aligned}\sigma_x^2&=\sum_{i=1}^{p} p_i(x_i-\bar{x})^2=\frac{1}{n}\sum_{i=1}^{p} n_i(x_i-\bar{x})^2=\frac{1}{\sum_{i=1}^{p} n_i}\sum_{i=1}^{p} n_i(x_i-\bar{x})^2\\ \sigma_y^2&=\sum_{i=1}^{q} p_i(y_i-\bar{y})^2=\frac{1}{m}\sum_{i=1}^{q} m_i(y_i-\bar{y})^2=\frac{1}{\sum_{i=1}^{q} m_i}\sum_{i=1}^{q} m_i(y_i-\bar{y})^2\end{aligned} \tag{5.7.168}$$

To continue, recall that we have previously proved the Huygens theorem and therefore:

$$\mathrm{V}(Z)=\sigma_z=\mathrm{E}(Z)-\mathrm{E}(Z)^2=\frac{1}{k}\sum_{i=1}^{k} k_i z_i^2-\bar{z}^2 \tag{5.7.169}$$

Therefore we have:

$$\begin{aligned}
\sigma_z^2 &= \frac{1}{k}\sum_{i=1}^{k} k_i z_i^2 - \bar{z}^2 = \frac{1}{k}\sum_{i=1}^{k} k_i z_i^2 - \left(\frac{n\bar{x}+m\bar{y}}{n+m}\right)^2 \\
&= \frac{1}{n+m}\left(\sum_{i=1}^{p} n_i x_i^2 + \sum_{i=1}^{q} m_i y_i^2\right) - \left(\frac{n\bar{x}+m\bar{y}}{n+m}\right)^2 \\
&= \frac{n\dfrac{1}{n}\displaystyle\sum_{i=1}^{p} n_i x_i^2 + m\dfrac{1}{m}\displaystyle\sum_{i=1}^{q} m_i y_i^2}{n+m} - \left(\frac{n\bar{x}+m\bar{y}}{n+m}\right)^2 \\
&= \frac{n\dfrac{1}{n}\displaystyle\sum_{i=1}^{p} n_i x_i^2 - n\bar{x}^2 + m\dfrac{1}{m}\displaystyle\sum_{i=1}^{q} m_i y_i^2 - m\bar{y}^2}{n+m} + \frac{n\bar{x}+m\bar{y}^2}{n+m} - \left(\frac{n\bar{x}+m\bar{y}}{n+m}\right)^2 \\
&= \frac{n\left(\dfrac{1}{n}\displaystyle\sum_{i=1}^{p} n_i x_i^2 - \bar{x}^2\right) + m\left(\dfrac{1}{m}\displaystyle\sum_{i=1}^{q} m_i y_i^2 - \bar{y}^2\right)}{n+m} + \frac{n\bar{x}+m\bar{y}^2}{n+m} - \left(\frac{n\bar{x}+m\bar{y}}{n+m}\right)^2 \\
&= \frac{n\sigma_x^2+m\sigma_y^2}{n+m} + \frac{n\bar{x}+m\bar{y}^2}{n+m} - \left(\frac{n\bar{x}+m\bar{y}}{n+m}\right)^2 \\
&= \frac{n\sigma_x^2+m\sigma_y^2}{n+m} + \frac{(n\bar{x}^2+m\bar{y}^2)(n+m)-(n\bar{x}+m\bar{y}^2)}{(n+m)^2} \\
&= \frac{n\sigma_x^2+m\sigma_y^2}{n+m} + \frac{(n^2\bar{x}^2+mn\bar{y}^2+mn\bar{x}^2+m^2\bar{y}^2)-(n^2\bar{x}^2+2n\bar{x}m\bar{y}+m^2\bar{y}^2)}{(n+m)^2} \\
&= \frac{n\sigma_x^2+m\sigma_y^2}{n+m} + \frac{mn\bar{y}^2+mn\bar{x}^2-2n\bar{x}m\bar{y}}{(n+m)^2} = \frac{n\sigma_x^2+m\sigma_y^2}{n+m} + nm\frac{\bar{y}^2+\bar{x}^2-2\bar{x}\bar{y}}{(n+m)^2} \\
&= \frac{n\sigma_x^2+m\sigma_y^2}{n+m} + nm\frac{(\bar{y}-\bar{x})^2}{(n+m)^2}
\end{aligned} \tag{5.7.170}$$

Redoing exactly the same developments with the unbiased variance we would get:

$$\sigma_z^2 = \frac{(n-1)\hat{\sigma}_x^2+(m-1)\hat{\sigma}_y^2}{n+m-1} + nm\frac{(\bar{y}-\bar{x})^2}{(n+m)(n+m-1)} \tag{5.7.171}$$

So we see that the overall variance is not equal to the sum of the variance (second common mistake in business)!!!

Consider now X being a random variable of mean μ (constant and determined value) and variance σ^2 (constant and determined value), we define the "reduced centered variable" by the relation:

$$\boxed{Y = \frac{X-\mu}{\sigma}} \tag{5.7.172}$$

Remark

When the real mean is unknowns and same for the variance, we denoted the above relation as following (various notation are represented):

$$Y=\frac{X-\hat{\mu}}{\hat{\sigma}}=\frac{X-\bar{X}}{S} \tag{5.7.173}$$

and this is named a "studentized variable".

Theorem 5.43. We prove in a very simple way by using the property of linearity of the mean and property of scalar multiplication of the variance that:

$$\mathrm{E}(Y)=0,\mathrm{V}(Y)=1 \tag{5.7.174}$$

Proof 5.43.1. For the proof we just use the definitions of the expected mean and variance (using Huygens theorem for this latter). So let us begin with the mean:

$$\mathrm{E}(Y)=\mathrm{E}\left(\frac{X-\mu}{\sigma}\right)=\frac{1}{\sigma}\mathrm{E}\left(X-\mu\right)=\frac{1}{\sigma}(\mathrm{E}(X)-\mathrm{E}(\mu))=\frac{1}{\sigma}(\mu-\mu)=0=\mu_Y \tag{5.7.175}$$

And now with the variance using the Huygens theorem:

$$\begin{aligned}\mathrm{V}(Y)&=\mathrm{E}(Y^2)-\mathrm{E}(Y)^2=\mathrm{E}(Y^2)-\mu_Y^2=\mathrm{E}(Y^2)-0^2=\mathrm{E}(Y^2)\\&=\mathrm{E}\left(\left(\frac{X-\mu}{\sigma}\right)^2\right)=\mathrm{E}\left(\frac{1}{\sigma^2}\left(X^2-2X\mu+\mu^2\right)\right)=\frac{1}{\sigma^2}\left(\mathrm{E}(X^2)-2\mu\mathrm{E}(X)+\mu^2\right)\\&=\frac{1}{\sigma^2}\left(\mathrm{E}(X^2)-2\mu\mu+\mu^2\right)=\frac{1}{\sigma^2}\left(\mathrm{E}(X^2)-\mu^2\right)=\frac{1}{\sigma^2}\left(\left(\mathrm{V}(X)+\mathrm{E}(X)^2\right)-\mu^2\right)\\&=\frac{1}{\sigma^2}\left(\mathrm{V}(X)+\mu^2-\mu^2\right)=\frac{1}{\sigma^2}\mathrm{V}(X)=\frac{1}{\sigma^2}\sigma^2=1\end{aligned} \tag{5.7.176}$$

■ Q.E.D.

Thus, any statistical distribution defined by a mean and standard deviation can be transformed into another distribution often easier to analyse statistical. Therefore making this transformation, we obtain a random variable for which the parameters of the distribution low are now useless to know. When we do that with other laws, and in the general case, when we speak of "pivotal variables".

Here are some important mathematical properties of the variance:

P1. Multiplication by a constant (scaling upon multiplication):

$$\mathrm{V}(\alpha X)=\sum_i f(x_i)(\alpha x_i-\alpha\mu)^2=\alpha^2\sum_i f(x_i)(x_i-\mu)^2=\alpha^2\mathrm{V}(X) \tag{5.7.177}$$

P2. Sum of two random variables (additivity under dependence):

$$\begin{aligned}
\mathrm{V}(X+Y) &= \sum_i \sum_j \left((x_i+y_i)-(\mu_X+\mu_Y)\right)^2 f(x_i,y_i)\\
&= \sum_i \sum_j \left((x_i-\mu_X)+(y_i-\mu_Y)\right)^2 f(x_i,y_i)\\
&= \sum_i \sum_j \left((x_i-\mu_X)^2+2(x_i-\mu_X)(y_i-\mu_Y)+(y_i-\mu_Y)^2\right)^2 f(x_i,y_i)\\
&= \sum_{i,j}(x_i-\mu_X)^2 f(x_i,y_i)+2\sum_{i,j}(x_i-\mu_X)(y_i-\mu_Y)f(x_i,y_i)\\
&+\sum_{i,j}(y_i-\mu_Y)^2 f(x_i,y_i)\\
&= \mathrm{V}(X)+2\sum_{i,j}(x_i-\mu_X)(y_i-\mu_Y)f(x_i,y_i)+\mathrm{V}(Y)\\
&= \mathrm{V}(X)+2\mathrm{E}\left[(X-\mu_X)(Y-\mu_Y)\right]+\mathrm{V}(Y)\\
&:= \mathrm{V}(X)+2\mathrm{cov}(X,Y)+\mathrm{V}(Y)
\end{aligned} \tag{5.7.178}$$

Where we meet for the first time the concept of "covariance" denoted by cov(). We will see further below at page 600 the general case to n random variables!

Obviously under independence we have $\mathrm{V}(X+Y)=\mathrm{V}(X)+\mathrm{V}(Y)$.

P3. Affine transformation:

$$\begin{aligned}
\mathrm{V}(\alpha+\beta X) &= \mathrm{E}\left[(\alpha+\beta X-\mathrm{E}(\alpha+\beta X))^2\right]\\
&= \mathrm{E}\left[(\alpha+\beta X-\alpha+\beta\mathrm{E}(X))^2\right]\\
&= \mathrm{E}\left[\beta^2(X-\mathrm{E}(X))^2\right]\\
&= \beta^2\mathrm{E}\left[(X-\mathrm{E}(X))^2\right]\\
&= \beta^2\mathrm{V}(X)
\end{aligned} \tag{5.7.179}$$

without too much surprises... The fact that $\mathrm{V}(\alpha+X)=\mathrm{V}(X)$ is named "invariance under addition" and the one that $\mathrm{V}(\beta X)=\beta^2\mathrm{V}(X)$ is named "scaling upon multiplication".

P4. Product of two random variables (using the Huygens theorem):

$$\mathrm{V}(X\cdot Y)=\mathrm{E}\left((XY)^2\right)-\mathrm{E}(XY)^2=\mathrm{E}(X^2Y^2)-\mathrm{E}(XY)^2 \tag{5.7.180}$$

And if the two random variables are independent, we get:

$$\mathrm{V}(X\cdot Y)=\mathrm{E}\left(X^2\right)\mathrm{E}\left(Y^2\right)-\mathrm{E}\left(X\right)^2\mathrm{E}\left(Y\right)^2 \tag{5.7.181}$$

What we can rewrite using once again the Huygens theorem:

$$\mathrm{V}(X\cdot Y)=(\mathrm{V}(X)-\mathrm{E}(X)^2)(\mathrm{V}(Y)-\mathrm{E}(Y)^2)-\mathrm{E}\left(X\right)^2\mathrm{E}\left(Y\right)^2 \tag{5.7.182}$$

We will assume as obvious that these four properties extend to the continuous case!

5.7.3.1.1.1 Semivariance

The "semi-variance" is an indicator that may have been proposed by Harry Markowitz instead of the variance for portfolio optimization especially.

Analyses in the labs may have shown that portfolios optimized for semivariance minimization (see section Economy page 7698) have better performance than those based on variance. Indeed, the variance considers extremes of positive and negative returns as having equal undesirability, whereas as we shall see, semi-variance considers only the negative part. On the other hand, if the distribution of returns tends to a perfect symmetry, the two methods tend (obviously) to give exactly the same result.

Definition (#5.7.129): The "semi-variance", also named "Lower Partial Standard Deviation" (LSPD), is a measure of the dispersion only of the realization of a random variables X which are less than the expected mean of this same random variable according to:

$$\boxed{\mathrm{V}_{\text{semi}}=\hat{\sigma}^2_{\text{semi}}=\mathrm{E}\left(\min(X-\mathrm{E}(X),0)^2\right)} \tag{5.7.183}$$

or denoted in the common discrete biased case, as standard deviation:

$$\sigma_{\text{semi}}=\sqrt{\frac{1}{n-1}\sum_{i=1}^{n}\left(\min(x_i-\hat{\mu}_X,0)^2\right)} \tag{5.7.184}$$

Remark

By the way the following trap must be avoid:

$$\mathrm{E}\left(\min(X-\mathrm{E}(X),0)^2\right)\neq\mathrm{V}\left(\min(X-\mathrm{E}(X),0)^2\right) \tag{5.7.185}$$

There trough this definition we see that the semivariance is similar to variance. However, it only considers observations below the mean. A useful tool in portfolio or asset analysis, semivariance provides a measure for "downside risk". While standard deviation and variance provide measures of volatility, semivariance only looks at the negative fluctuations of an asset. By neutralizing all values above the mean, or an investor's target return, semivariance estimates the average loss that a portfolio could incur.

For risk averse investors, solving for optimal portfolio allocations by minimizing semivariance would limit the likelihood of a large loss.

✍**Example:**

Let us consider the small following table:

Date	**Price**	**Return (X)**	$(\min(X-\mathbf{E}(X),0))^2$
March	20		
April	19	-5%	$(-4.6\%)^2$
May	17.10	-10%	$(-9.6\%)^2$
June	18.81	$+10\%$	0^2
July	19.25	$+5\%$	0^2
August	19.36	-1.99%	$(-1.59\%)^2$
Arithmetic mean:		$\mathrm{E}(X)\cong 0.4\%$	

The semi-variance value is then:

$$\mathrm{V}_{\text{semi}}=\mathrm{E}\left(\min(X-\mathrm{E}(X),0)^2\right)=\frac{1}{5}\left[(-4.6\%)^2+(-9.6\%)^2+(-1.59\%)^2\right]\cong 0.232\% \tag{5.7.186}$$

5.7.3.1.2 Discrete Covariance

We have seen in one of the last equations earlier above the concept of "covariance" for which we will determine a more convenient expression later:

$$\boxed{\mathrm{cov}(X,Y)=\mathrm{c}_{X,Y}=\mathrm{E}\left[(X-\mu_X)(Y-\mu_Y)\right]} \tag{5.7.187}$$

The concept of covariance can be understood geometrically as illustrated below (we will define further below the concept of correlation abbreviated Corr in the figure):

- The rectangle is green when either:
  - Both x and y are greater than their respective means
  - Both x and y are less than their respective means
- The rectangle is red when either:
  - x is greater than μ_X but y is less than μ_Y
  - x is less than μ_X but y is greater than μ_Y

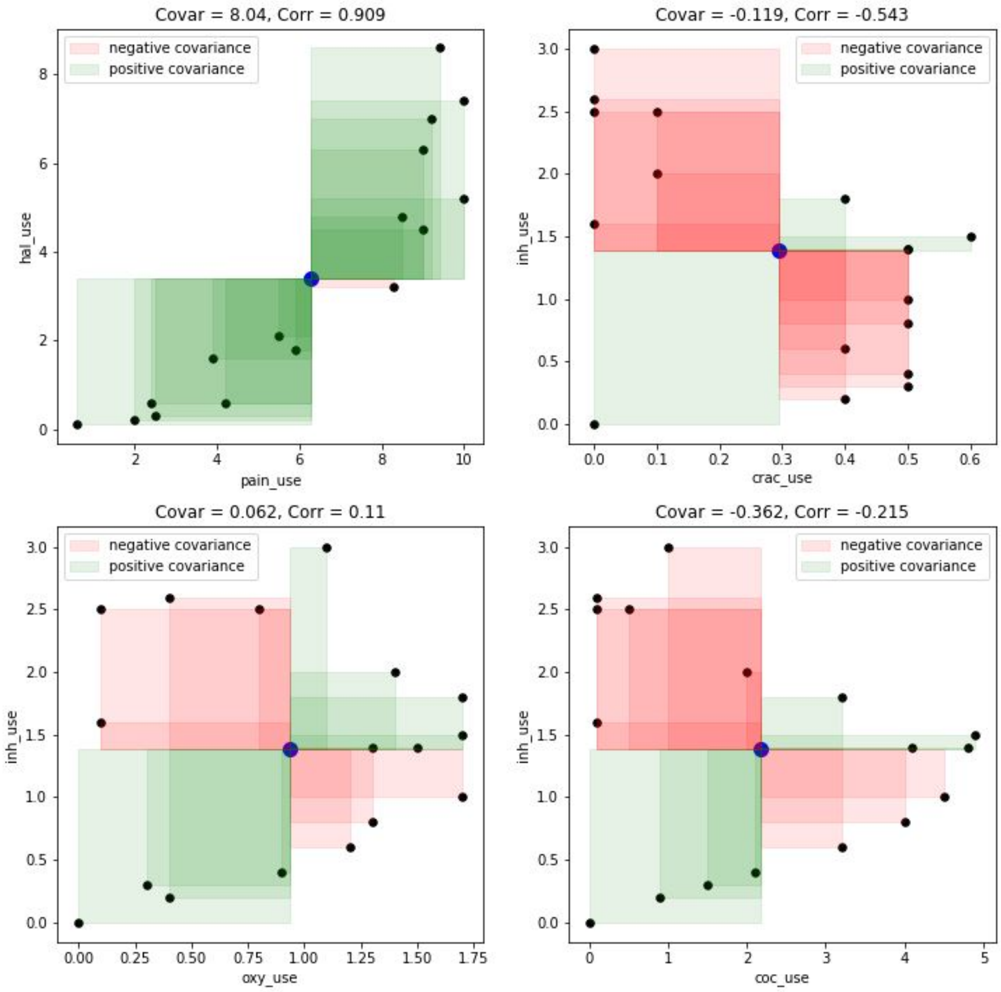

Figure 5.112: **Geometric interpretation of covariance**

We introduce now a more general and very important expression of the covariance in many application fields:

$$\begin{aligned}
\mathrm{V}(X+Y+Z) &= \sum_i\sum_j\sum_k ((x_i+y_j+z_k)-(\mu_X+\mu_Y+\mu_Z))^2 f(x_i,y_j,z_k)\\
&= \sum_i\sum_j\sum_k ((x_i-\mu_X)+(y_j-\mu_Y)+(z_k-\mu_Z))^2 f(x_i,y_j,z_k)\\
&= \sum_i\sum_j\sum_k (A+B+C)^2 f(x_i,y_j,z_k)\\
&= \sum_i\sum_j\sum_k (A^2+B^2+C^2+2AB+2BC+2AC) f(x_i,y_j,z_k)\\
&= \mathrm{V}(X)+\mathrm{V}(Y)+\mathrm{V}(Z)+2\sum_i\sum_j\sum_k (AB+BC+AC) f(x_i,y_j,z_k)\\
&= \mathrm{V}(X)+\mathrm{V}(Y)+\mathrm{V}(Z)+2\mathrm{cov}(X,Y)+2\mathrm{cov}(Y,Z)+2\mathrm{cov}(X,Z)
\end{aligned} \tag{5.7.188}$$

Remark

Some readers may have noticed that with 1 variable, we have 0 covariance terms, with 2 variables we have 1 covariance term, with 3 variables we have $2+2+2=6$ covariance terms, and continuing we would see that we have in the general case $n(n-1)$ covariance terms for n variables.

Now we change the notation to simplify even more:

$$\begin{aligned}\mathrm{V}(X_1+X_2+X_3)&=\mathrm{V}(X_1)+\mathrm{V}(X_2)+\mathrm{V}(X_3)+2\mathrm{cov}(X_1,X_2)+2\mathrm{cov}(X_2,X_3)+2\mathrm{cov}(X_1,X_3)\\&=\sum_{i=1}^{3}\mathrm{V}(X_i)+2\sum_{i<j}^{3}\mathrm{cov}(X_i,X_j)\end{aligned} \tag{5.7.189}$$

Therefore in the general case:

$$\boxed{\mathrm{V}\left(\sum_{i=1}^{n}X_i\right)=\sum_{i=1}^{n}\mathrm{V}(X_i)+2\sum_{i<j}^{n}\mathrm{cov}(X_i,X_j)} \tag{5.7.190}$$

Or using standard deviation:

$$\boxed{\sigma_{\sum_{i=1}^{n}X_i}=\sqrt{\sum_{i=1}^{n}\sigma_{X_i}^2+2\sum_{i<j}^{n}\mathrm{cov}(X_i,X_j)}} \tag{5.7.191}$$

Using the properties of the mean (especially $\mathrm{E}(X)=c^{te}$ and $\mathrm{E}(c^{te})=c^{te}$) we can write the covariance in a much simpler way for calculation purposes:

$$\begin{aligned}\mathrm{cov}(X,Y)&=\mathrm{E}\left[(X-\mathrm{E}(X))(Y-\mathrm{E}(Y))\right]=\mathrm{E}\left[XY-\mathrm{E}(X)Y-X\mathrm{E}(Y)+\mathrm{E}(X)\mathrm{E}(Y)\right]\\&=\mathrm{E}(XY)-\mathrm{E}(\mathrm{E}(X)Y)-\mathrm{E}(X\mathrm{E}(Y))+\mathrm{E}(\mathrm{E}(X)\mathrm{E}(Y))\\&=\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)-\mathrm{E}(X)\mathrm{E}(Y)+\mathrm{E}(X)\mathrm{E}(Y)\\&=\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)\end{aligned} \tag{5.7.192}$$

and we obtain the relation widely used in statistics and finance in practice named the "covariance formula"...:

$$\boxed{\mathrm{c}_{X,Y}=\mathrm{cov}(X,Y)=\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)} \tag{5.7.193}$$

which is however best known when written as:

$$\mathrm{c}_{X,Y}=\mathrm{cov}(X,Y)=\frac{1}{n}\sum_{i}x_iy_i-\bar{x}\bar{y} \tag{5.7.194}$$

If $X=Y$ (equivalent to a univariate covariance) we fall back again on the Huygens theorem:

$$\boxed{\mathrm{c}_{X,X}=\mathrm{cov}(X,X)=\mathrm{E}(XX)-\mathrm{E}(X)\mathrm{E}(X)=\mathrm{E}(X^2)-\mathrm{E}(X)^2} \tag{5.7.195}$$

Remark

Statistics can be partitioned according to the number of random variables we study. Thus, when a single random variable is studied, we speak of "univariate statistics", for two random variables of "bivariate statistics" and in general, of "multivariate statistics".

If and only if the variables are equally likely, we find the covariance in the literature in the following form, sometimes named "Pearson covariance", which derives from calculations that we have done previously with the mean:

$$\mathrm{c}_{X,Y}=\frac{1}{n}\sum_{i=1}^{n}(y_i-\mu_Y)(x_i-\mu_X) \tag{5.7.196}$$

Covariance is a measure of the simultaneous variation of X and Y. Indeed, if X and Y generally grow simultaneously, the products $(y_i-\mu_Y)(x_i-\mu_X)$ will be positive (positively correlated), whereas if Y decreases as X increases, these same products will be negative (negative correlation).

Note that if we distribute the terms of the last equation, we have:

$$\begin{aligned}\mathrm{c}_{X,Y}=\mathrm{cov}(X,Y)&=\frac{1}{n}\sum_{i=1}^{n}(y_i-\mu_Y)(x_i-\mu_X)=\frac{1}{n}\sum_{i=1}^{n}(y_i-\bar{y})(x_i-\bar{x})\\&=\frac{1}{n}\sum_{i=1}^{n}x_i(y_i-\bar{y})-\bar{x}(y_i-\bar{y})=\frac{1}{n}\left(\sum_{i=1}^{n}x_i(y_i-\bar{y})-\bar{x}\sum_{i=1}^{n}(y_i-\bar{Y})\right)\end{aligned} \tag{5.7.197}$$

and we have already shown that the sum of the deviations from the mean is zero. Hence we get another common way to write the covariance:

$$\mathrm{c}_{X,Y}=\mathrm{cov}(X,Y)=\frac{1}{n}\sum_{i=1}^{n}x_i(y_i-\bar{y}) \tag{5.7.198}$$

and by symmetry:

$$\mathrm{c}_{X,Y}=\mathrm{cov}(X,Y)=\frac{1}{n}\sum_{i=1}^{n}y_i(x_i-\bar{x}) \tag{5.7.199}$$

So in the end, in the equiprobable case, we finally have the equivalent three important relations used in various sections of this textbook:

$$\boxed{\begin{aligned}\mathrm{c}_{X,Y}&=\mathrm{cov}(X,Y)=\frac{1}{n}\sum_{i=1}^{n}(y_i-\bar{y})(x_i-\bar{x})\\\mathrm{c}_{X,Y}&=\mathrm{cov}(X,Y)=\frac{1}{n}\sum_{i=1}^{n}x_iy_i-\bar{x}\bar{y}\\\mathrm{c}_{X,Y}&=\mathrm{cov}(X,Y)=\frac{1}{n}\sum_{i=1}^{n}x_i(y_i-\bar{y})=\frac{1}{n}\sum_{i=1}^{n}y_i(x_i-\bar{x})\end{aligned}} \tag{5.7.200}$$

In the section Theoretical Computing for the study of linear regression (page 6324) and factor analysis we will need the explicit expression of the bilinearity property of the variance. To see what it is exactly, consider three random variables X, Y and Z and two constants a and b. Then using the third relation given above, we have:

$$\begin{aligned}\text{cov}\,(Y, aX+bZ) &= \frac{1}{n}\sum_i (y_i-\bar{y})(ax_i+bz_i) = \frac{1}{n}\sum_i \left[(y_i-\bar{y})ax_i+(y_i-\bar{y})bz_i\right]\\ &= \frac{1}{n}\left[\sum_i (y_i-\bar{y})ax_i+\sum_i (y_i-\bar{y})bz_i\right]\\ &= a\frac{1}{n}\sum_i (y_i-\bar{y})x_i+b\frac{1}{n}\sum_i (y_i-\bar{y})z_i\\ &= a\text{cov}(X,Y)+b\text{cov}(Y,Z)\end{aligned} \tag{5.7.201}$$

The last relation is also important and will be used in several sections of this textbook (Economy page 7485, Numerical Methods page 6272). It also allows us to directly obtain the covariance for the sums of various random variables.

✍**Example:**

If X, Y, Z, T are four random variables defined on the same population, we want to compute the following covariance:

$$\text{cov}(3X+5Y, 4Z-2T) \tag{5.7.202}$$

We will develop that in two phases (this is also why we name that "bilinearity property"). First with respect to the second argument (random choice!):

$$\text{cov}(3X+5Y, 4Z-2T) = 4\text{cov}(3X+5Y, Z) - 2\text{cov}(3X+5Y, T) \tag{5.7.203}$$

And then with respect to the first:

$$\text{cov}(3X+5Y, 4Z-2T) = 4\left[3\text{cov}(X,Z)+5\text{cov}(Y,Z)\right]-2\left[3\text{cov}(X,T)+5\text{cov}(Y,T)\right] \tag{5.7.204}$$

So in the end:

$$\text{cov}(3X+5Y, 4Z-2T) = 12\text{cov}(X,Z)+20\text{cov}(Y,Z)-6\text{cov}(X,T)-10\text{cov}(Y,T) \tag{5.7.205}$$

There is an elegant and simple method to remember how to calculate the covariance of two random variables. Indeed, remembering that we have proved just earlier that:

$$\begin{aligned}\text{V}(X+Y) &= \text{V}(X)+\text{V}(Y)+2\text{cov}(X,Y)\\ \text{V}(X-Y) &= \text{V}(X)+\text{V}(Y)-2\text{cov}(X,Y)\end{aligned} \tag{5.7.206}$$

It comes by subtracting these two relations and simplifying / reordering:

$$\boxed{\text{cov}(X,Y) = \frac{\text{V}(X+Y)-\text{V}(X-Y)}{4}} \tag{5.7.207}$$

and that's it! A simple way to remember the compute the covariance.

Now, consider a set of random vectors $\vec{X}_i := X_i$ of components $(x_1, x_2, \ldots, x_n)_i$. The calculation of the covariance of the components by pairs gives what is named the "covariance matrix" (a tool widely used in finance, management and statistical numerical methods!).

Indeed, we define the component (m, n) of the covariance matrix by:

$$\text{cov}_{X_m,X_n} = \text{E}\left[(X_m - \mu_{X_m})(X_n - \mu_{X_n})\right] := \text{c}_{m,n} \tag{5.7.208}$$

We can therefore write a symmetric matrix (usually in practice it must be a square matrix...) in the form:

$$\Sigma = \begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{n1} & c_{n2} & \cdots & c_{nn} \end{bmatrix} \tag{5.7.209}$$

where Σ is the usual tradition letter to denote the "covariance matrix".

By symmetry and because it is a square n by n matrix only the number $\dfrac{n(n+1)}{2}$ of components is useful for us to determine the whole matrix (trivial but important information for when we will study the structural equation modelling in the Numerical Methods section).

This matrix has the remarkable property that if we take the set of all random vectors and we calculate the covariance matrix, then the diagonal will give us obviously the variances of each pair of vectors (see examples in the chapters Economics, Numerical Methods or Industrial Engineering) because we have for recall:

$$\text{cov}_{X_m,X_m} = \text{E}\left[(X_m - \mu_{X_m})(X_n - \mu_{X_m})\right] = \text{E}\left[(X_m - \mu_{X_m})^2\right] = \text{V}(X_m) = \sigma^2_{X_m} \tag{5.7.210}$$

Hence the name "variance-covariance matrix":

$$\Sigma = \begin{bmatrix} \text{V}_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & \text{V}_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{n1} & c_{n2} & \cdots & \text{V}_{nn} \end{bmatrix} = \begin{bmatrix} \sigma^2_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & \sigma^2_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{n1} & c_{n2} & \cdots & \sigma^2_{nn} \end{bmatrix} \tag{5.7.211}$$

And this is a little bit abusively sometimes written as:

$$\Sigma = \begin{bmatrix} \sigma^2_{11} & \sigma_{12} & \cdots & \sigma_{1n} \\ \sigma_{21} & \sigma^2_{22} & \cdots & \sigma_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{n1} & \sigma_{n2} & \cdots & \sigma^2_{nn} \end{bmatrix} \tag{5.7.212}$$

This matrix has the advantage of quickly showing what pairs of random variables have a negative covariance and there... for which random variable the variance of the sum is smaller than the sum of the variances!

Remark

As we already mention it, this matrix is very important and we will often see it again in the section Economy during our study of modern portfolio theory (page 7698) and also for data mining techniques in the section of Theoretical Computing (page 6768) and also for principal components analysis (page 1213) and also in Industrial Engineering during our study of bivariate control charts (page 8934).

Recall now that we have an axiom in probability (see section Probabilities page 476) which lead us to the fact that two events A and B are independent if and only if:

$$P(A\cap B)=P(A)P(B) \tag{5.7.213}$$

Similarly, by extension, we define the independence of discrete random variables.

Definition (#5.7.130): Let X,Y be two discrete random variables. We say that X,Y are independent if and only if:

$$\forall x,y\in\mathbb{R}\quad P(X=x,Y=y)=P(X=x)P(Y=y) \tag{5.7.214}$$

More generally, the discrete variables $X_1,X_2,\ldots,X_n$ are independent (in block) if:

$$\forall x_1,\ldots,x_n\in\mathbb{R}\quad P(X_1=x_1,X_2=x_2,\ldots,X_3=x_3)=\prod_{i=1}^{n}P(X_i=x_i) \tag{5.7.215}$$

Theorem 5.44. The independence of two random variables implies that their covariance is zero (the opposite is false!).

Proof 5.44.1. We will prove this in the case where the random variables take only a finite number of values $\{x_i\}_I$ and $\{y_j\}_J$, respectively, with I,J finite sets.

For the proof let us recall that:

$$\begin{aligned}\mathrm{E}(XY)&=\sum_{i,j}P(X=x_i,Y=y_j)x_iy_j=\sum_{i,j}P(X=x_i)P(Y=y_j)x_iy_j\\&=\sum_{i}P(X=x_i)x_i\sum_{j}P(Y=y_j)y_j=\mathrm{E}(X)\mathrm{E}(Y)\end{aligned} \tag{5.7.216}$$

and therefore:

$$\mathrm{c}_{X,Y}=\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)=\mathrm{E}(X)\mathrm{E}(Y)-\mathrm{E}(X)\mathrm{E}(Y)=0 \tag{5.7.217}$$

Remark

So smaller is the covariance (near to zero), more the series are independent. Conversely, the greater the covariance (in absolute value) higher the series are dependent.

Given that:

$$\mathrm{V}(X+Y)=\mathrm{V}(X)+\mathrm{V}(Y)+2c_{X,Y} \tag{5.7.218}$$

and the fact that if X and Y are independent we have $c_{X,Y}=0$. Then:

$$\mathrm{V}(X+Y)=\mathrm{V}(X)+\mathrm{V}(Y) \tag{5.7.219}$$

More generally if $X_1, \ldots, X_n$ are independent (in block) then for any discrete or continuous statistical distribution law (!) we have using the two most common notations:

$$\mathrm{V}\left(\sum_{i=1}^{n} X_i\right) = \sum_{i=1}^{n} \mathrm{V}(X_i) \tag{5.7.220}$$

Or using the standard deviation:

$$\sigma_{\sum_{i=1}^{n} X_i} = \sqrt{\sum_{i=1}^{n} \sigma_{X_i}^2} \tag{5.7.221}$$

■ Q.E.D.

There is another important relation that we will need for our study of Data Mining/Machine Learning and especially to compare different models and involving the covariance matrix.

Let $X = (X_i)$ be an $n \times 1$ random vector and let A be an $n \times n$ symmetric matrix. If $\mathrm{E}(X) = \mu$ and $\mathrm{V}(X) = \Sigma = \sigma_{ij}$ then $\mathrm{E}[X^T AX] = \mathrm{tr}(A\sigma) + \mu^T A\mu$ (keeping in mind that $X^T AX$ is a 1×1 matrix, or in other words: a scalar!).

To prove this first notice that:

$$X^T AX = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij} X_i X_j. \tag{5.7.222}$$

So what is its expectation? Clearly we have first by using the linearity proper of the expected mean:

$$\mathrm{E}[X^T AX] = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij} \mathrm{E}[X_i X_j] \tag{5.7.223}$$

Applying the covariance relation proved just earlier above:

$$\mathrm{cov}(X,Y) = \mathrm{E}(XY) - \mathrm{E}(X)\mathrm{E}(Y) \Leftrightarrow \mathrm{E}(XY) = \mathrm{cov}(X,Y) + \mathrm{E}(X)\mathrm{E}(Y) \tag{5.7.224}$$

then we get:

$$\mathrm{E}[X^T AX] = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}\mathrm{E}[X_i X_j] = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}(\sigma_{ij} + \mu_i\mu_j) \tag{5.7.225}$$

As Σ is symmetric:

$$\begin{aligned}\mathrm{E}[X^T AX] &= \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}(\sigma_{ij} + \mu_i\mu_j) = \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}\sigma_{ji} + \sum_{i=1}^{n}\sum_{j=1}^{n} a_{ij}\mu_i\mu_j \\ &= \sum_{i=1}^{n} [A\Sigma]_{ii} + \mu^T A\mu = \mathrm{tr}(A\Sigma) + \mu^T A\mu\end{aligned} \tag{5.7.226}$$

The following relation will be important to us during our study of the Akaike information criterion (see section Numerical Methods page 6420):

$$\boxed{\mathrm{E}[X^T AX] = \mathrm{tr}(A\Sigma) + \mu^T A\mu} \tag{5.7.227}$$

Notice that the notation above is common in the field of statistics but more rigorously we should write:

$$\boxed{\mathrm{E}[\vec{x}^T A\vec{x}] = \mathrm{tr}(A\Sigma) + \vec{\mu}^T A\vec{\mu}} \tag{5.7.228}$$

We need also another property of the covariance matrix for our study of Akaike information criterion (see section Numerical Methods page 6420). Let us consider $\vec{x} \in \mathbb{R}^p$ be a random (column) vector with covariance matrix $\sigma \in \mathbb{R}^{p\times p}$. Let $A \in \mathbb{R}^{p\times p}$ be a non-random matrix. Then:

$$\begin{aligned}
\mathrm{V}(A\vec{x}) &= \mathrm{E}[(A\vec{x} - \mathrm{E}(A\vec{x}))(A\vec{x} - \mathrm{E}(A\vec{x}))^T]\\
&= \mathrm{E}[(A\vec{x} - A\mathrm{E}(\vec{x}))(A\vec{x} - A\mathrm{E}(\vec{x}))^T]\\
&= \mathrm{E}[(A\vec{x} - A\mathrm{E}(\vec{x}))(\vec{x}^T A^T - \mathrm{E}(\vec{x})^T A^T)]\\
&= \mathrm{E}[A(\vec{x} - \mathrm{E}(\vec{x}))(\vec{x} - \mathrm{E}(\vec{x}))^T A^T]\\
&= A\,\underbrace{\mathrm{E}[(\vec{x} - \mathrm{E}(\vec{x}))(\vec{x} - \mathrm{E}(\vec{x}))^T]}_{=\Sigma}\,A^T\\
&= A\Sigma A^T
\end{aligned} \tag{5.7.229}$$

We get the same result if we replace the vector $\vec{x}$ by a matrix X such that:

$$\mathrm{V}(AX) = A\Sigma A^T \tag{5.7.230}$$

5.7.3.1.2.1 Quasi-correlation matrix

In practice, some financial analysts estimate qualitatively the matrix of correlations based on their experience, we then talk about the "quasi-correlation matrix", and remember that the variance-covariance matrix and the matrix of correlations are the same thing but with two different perspectives, however it is not possible to make an estimate randomly (without rules).

Indeed, let us consider n real random variables $X_1, \ldots, X_n$ of respective means $\mu_1, \ldots, \mu_n$. Let us denote exceptionally by Σ the symmetric matrix of variances-covariances defined by:

$$\Sigma = \begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n}\\ c_{21} & c_{22} & \cdots & c_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ c_{n1} & c_{n2} & \cdots & c_{nn}\end{bmatrix} = \begin{bmatrix} \mathrm{V}(X_1) & \mathrm{cov}(X_1,X_2) & \cdots & \mathrm{cov}(X_1,X_n)\\ \mathrm{cov}(X_2,X_1) & \mathrm{V}(X_2) & \cdots & \mathrm{cov}(X_2,X_n)\\ \vdots & \vdots & \ddots & \vdots\\ \mathrm{cov}(X_n,X_1) & \mathrm{cov}(X_n,X_2) & \cdots & \mathrm{V}(X_n)\end{bmatrix} \tag{5.7.231}$$

Let us prove that Σ is positive semi-definite (see section Linear Algebra page 1957):

Proof 5.44.2. Given $\vec{\alpha} = (\alpha_1, \ldots, \alpha_n)^T$ a vector of $\mathbb{R}^n$. We have:

$$\begin{aligned}
\mathrm{V}\left(\sum_{i=1}^n \alpha_i X_i\right) &= \mathrm{E}\left(\left(\sum_{i=1}^n \alpha_i(X_i - \mu_i)\right)^2\right) = \mathrm{E}\left(\sum_{i,j} \alpha_i\alpha_j(X_i - \mu_i)(X_j - \mu_j)\right)\\
&= \sum_{,j} \alpha_i\alpha_j \mathrm{E}\left((X_i - \mu_i)(X_j - \mu_j)\right) = \sum_{i,j} \alpha_i\alpha_j \mathrm{cov}(X_i, X_j) = \vec{\alpha}^T\Sigma\vec{\alpha}
\end{aligned} \tag{5.7.232}$$

Therefore:

$$\vec{\alpha}^T\Sigma\vec{\alpha} \geq 0 \tag{5.7.233}$$

Since the variance is positive or zero by construction! Which means that Σ is semi-positive. This is a very important property for many statistical applications (Mahalonobis distance, Cholesky decomposition, etc.).

■ Q.E.D.

Now, by the generality of $\vec{\alpha}$, let us admit (nothing prevents us to do so!) that the latter is an eigenvector (see section Linear Algebra page 1997). Then, since:

$$\vec{\alpha}^T\Sigma\vec{\alpha} \geq 0 \tag{5.7.234}$$

and since by definition of their eigenvalues and eigenvectors:

$$\Sigma\vec{\alpha} = \lambda_i\vec{\alpha} \tag{5.7.235}$$

Then we have:

$$\vec{\alpha}^T\Sigma\vec{\alpha} = \vec{\alpha}^T\lambda_i\vec{\alpha} \geq 0 \tag{5.7.236}$$

And let us concentrate on the right term:

$$\vec{\alpha}^T\lambda_i\vec{\alpha} \geq 0 \tag{5.7.237}$$

Since the eigenvalue is a scalar we can rearrange this for example in the following form (commutativity):

$$\left(\vec{\alpha}^T\vec{\alpha}\right) \geq 0 \tag{5.7.238}$$

and as $\vec{\alpha}^T\vec{\alpha}$ is necessarily positive then the λ_i can only be positive or null.

So we got a way to check that our matrix of variances-covariances (or correlation) is indeed what it is supposed to be !!!

Moreover, as we have demonstrated in our study of the spectral theorem in the Linear Algebra section page 2004 that for a matrix such that is Σ (symmetric, real, positive semi-definite):

$$\det(\Sigma) = \prod \lambda_i \tag{5.7.239}$$

Then another way of controlling is Σ is positive semi-definite is that the determinant of the variance-covariance matrix is positive or zero. And keep in mind that if the determinant is zero, then the matrix is not invertible! Hence the variance-covariance matrix is not always invertible!

Remark

However, the reciprocal is false (obviously!), we can have a positive determinant without the matrix being positive. While for eigenvalues there is equivalence: positive matrix is equivalent to all eigenvalues are positive.

5.7.3.1.2.2 Anscombe's famous quartet

Anscombe's quartet comprises four datasets that have nearly identical elementary statistical properties, yet appear very different when graphed or analysed with undergraduate statistics rather than high-school one. Each dataset consists of eleven (x, y) points. They were constructed in 11973 (holocene calendar) by the statistician Francis Anscombe to demonstrate both the importance of graphing data before analysing it and the effect of outliers on statistical properties. This quartet is also used to test if an analytical tool can be accepted a "statistics-compliant" (as the six corresponding used statistics should be the minimum provided by any high-school level analytical tool!).

The datasets are as follows. The x values are the same for the first three datasets:

I		II		III		IV	
x	y	x	y	x	y	x	y
10.0	8.04	10.0	9.14	10.0	7.46	8.0	6.58
8.0	6.95	8.0	8.14	8.0	6.77	8.0	5.76
13.0	7.58	13.0	8.74	13.0	12.74	8.0	7.71
9.0	8.81	9.0	8.77	9.0	7.11	8.0	8.84
11.0	8.33	11.0	9.26	11.0	7.81	8.0	8.47
14.0	9.96	14.0	8.10	14.0	8.84	8.0	7.04
6.0	7.24	6.0	6.13	6.0	6.08	8.0	5.25
4.0	4.26	4.0	3.10	4.0	5.39	19.0	12.50
12.0	10.84	12.0	9.13	12.0	8.15	8.0	5.56
7.0	4.82	7.0	7.26	7.0	6.42	8.0	7.91
5.0	5.68	5.0	4.74	5.0	5.73	8.0	6.89

Table 5.37: **Anscombe's quartet**

The quartet is still often used to illustrate the importance of looking at a set of data graphically before starting to analyse according to a particular type of relation, and the inadequacy of basic statistic properties for describing realistic datasets.

With Microsoft® Excel® 14.0.7166 we get:

	I		II		III		IV	
	x	y	x	y	x	y	x	y
	10.00	8.04	10.00	9.14	10.00	7.46	8.00	6.58
	8.00	6.95	8.00	8.14	8.00	6.77	8.00	5.76
	13.00	7.58	13.00	8.74	13.00	12.74	8.00	7.71
	9.00	8.81	9.00	8.77	9.00	7.11	8.00	8.84
	11.00	8.33	11.00	9.26	11.00	7.81	8.00	8.47
	14.00	9.96	14.00	8.10	14.00	8.84	8.00	7.04
	6.00	7.24	6.00	6.13	6.00	6.08	8.00	5.25
	4.00	4.26	4.00	3.10	4.00	5.39	19.00	12.50
	12.00	10.24	12.00	9.13	12.00	8.15	8.00	5.56
	7.00	4.82	7.00	7.26	7.00	6.42	8.00	7.91
	5.00	5.68	5.00	4.74	5.00	5.73	8.00	6.89
Mean	9.0000	7.5009	9.0000	7.5009	9.0000	7.5000	9.0000	7.5009
Median	9.0000	7.5800	9.0000	8.1400	9.0000	7.1100	8.0000	7.0400
Variance	10.0000	3.7521	10.0000	3.7524	10.0000	3.7478	10.0000	3.7484
Skewness	0.0000	−0.0650	0.0000	−1.3158	0.0000	1.8555	3.3166	1.5068
Kurtosis	1.2000	−0.5349	−1.2000	0.8461	1.2000	4.3841	11.0000	3.1513
Correlation	0.8164		0.8162		0.8164		0.8165	

Table 5.38: **Anscombe's quartet statistics summary**

As we can see with elementary statistical indicators it is almost impossible to guess a difference between the four data sets. But if we use the skewness or the kurtosis (see page 636) this change everything! The mutual information criterion (see section Statistical Mechanics page 3529) can also discriminate between the four plots.

Looking to the corresponding charts we get the same conclusion:

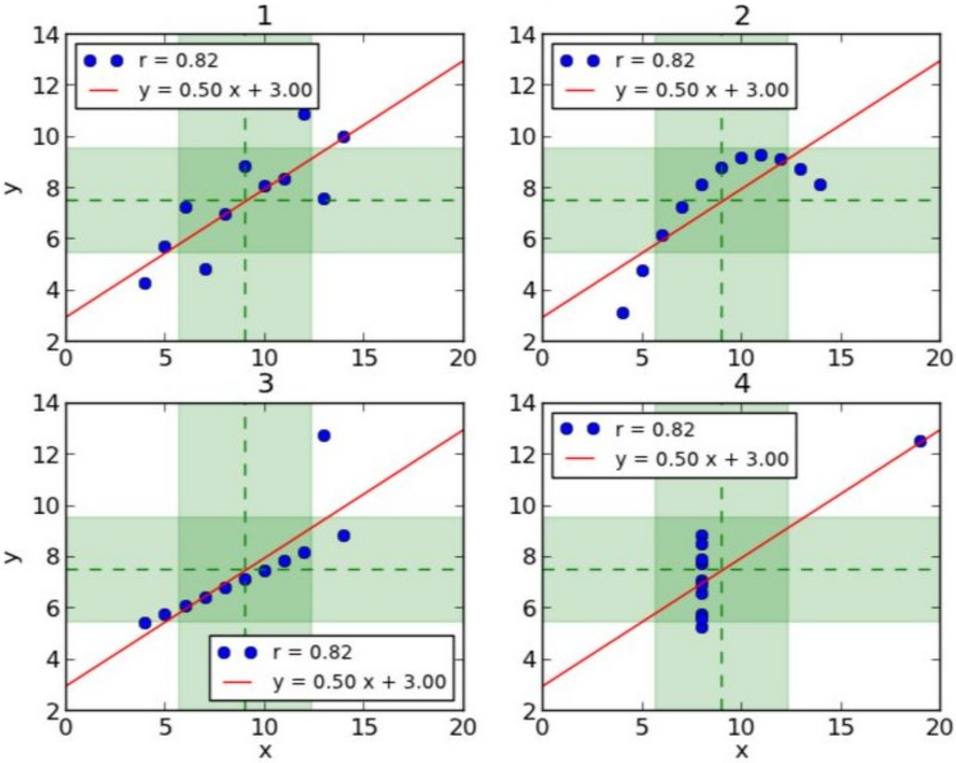

Figure 5.113: **Anscombe's quartet graphs summary**

5.7.3.1.3 Mean and Variance of the Average

Often in statistics, it is (verrrrry!) useful to determine the standard deviation of the sample mean and to work with it to get important analytical results in management and manufacturing. Let's see what it is!

Given the average of a series of terms, each determined by the measurement of several values (it is in fact its estimator in a particular case as we will see later):

$$\bar{X}=\frac{1}{n}\left(X_1+X_2+\ldots+X_n\right) \tag{5.7.240}$$

then using the properties of the mean:

$$\mathrm{E}\left(\bar{X}\right)=\frac{1}{n}\left(\mathrm{E}(X_1)+\mathrm{E}(X_2)+\ldots+\mathrm{E}(X_n)\right) \tag{5.7.241}$$

and if all the random variables are independent and identically distributed then we have:

$$\mathrm{E}\left(\bar{X}\right)=\frac{1}{n}\left(\mu+\mu+\ldots+\mu\right)=\frac{1}{n}n\mu=\mu \tag{5.7.242}$$

Remark

We will prove much further below that if all the random variables are independent and identically distributed with finite variance, then the mean follows asymptotically what we name a "Normal distribution".

For the variance, the same reasoning applies:

$$\mathrm{V}(\bar{X})=\sigma_{\bar{X}}^2=\frac{1}{n^2}\left(\mathrm{V}(X_1)+\mathrm{V}(X_2)+\ldots+\mathrm{V}(X_n)\right)=\frac{1}{n^2}\left(\sigma_1^2+\sigma_2^2+\ldots+\sigma_2^n\right) \tag{5.7.243}$$

And if the random variables are independent and identically distributed (we will study further the very important case current in practice where the last condition is not satisfied):

$$\boxed{\mathrm{V}(\bar{X})=\sigma_{\bar{X}}^2=\frac{\sigma^2}{n}} \tag{5.7.244}$$

Then we get the "standard deviation of the mean" also named "standard error" or "non-systematic variation":

$$\boxed{\mathrm{SE}=\sigma_{\bar{X}}=\frac{\sigma}{\sqrt{n}}} \tag{5.7.245}$$

and this is strictly the standard deviation of the estimator of mean!

The more intuitive form to express the Standard Error in terms of percent for non-analytical workers, managers and chief executives is named "Relative Standard Error (RSE)" which is the expression of the Standard Error as percent, that is:

$$\boxed{\mathrm{RSE}=\frac{\sigma_{\bar{X}}}{\bar{X}}} \tag{5.7.246}$$

The latter is quite useful when we have to deal with many variables with different units!!

The value of $\sigma_{\bar{X}}$ is available in many softwares including Microsoft® Excel® charts (but there is no built-in function in Microsoft® Excel®) and is written with the standard deviation (as above) or with the notation of the variance (then we only have to take the square root...).

Note that the last relation can be used even if the average of n random variables is not the same! The main condition is just that the standard deviations are all equal and this is the case in the industry (production).

We then have:

$$\boxed{\begin{aligned} &\text{E}(S_n)=n\mu && \text{E}(M_n)=\mu \\ &\text{V}(S_n)=\sigma_{S_n}^2=n\sigma^2 && \text{V}(M_n)=\sigma_{M_n}^2=\frac{\sigma^2}{n} \end{aligned}} \tag{5.7.247}$$

where S_n is the sum of n independent identically distributed random variables and M_n their estimated average.

The reduced centered variable that we introduced earlier:

$$Y=\frac{X-\mu}{\sigma} \tag{5.7.248}$$

can then be written in several very useful ways:

$$\boxed{Y=\frac{S_n-n\mu}{\sigma_{S_n}\sqrt{n}}=\frac{M_n-\mu}{\sigma_{M_n}/\sqrt{n}}} \tag{5.7.249}$$

Furthermore, assuming that the reader already knows what is a Normal distribution $\mathcal{N}(\mu,\sigma)$, we will show later in detail because it is extremely important (!) that the probability of the random variable $\bar{X}$, average of n identically distributed and linearly independent random variables, has for law (obviously):

$$\mathcal{N}\left(\mu,\frac{\sigma}{\sqrt{n}}\right) \tag{5.7.250}$$

5.7.3.1.4 Coefficient of Correlation

Now consider X and Y two random variables having for covariance:

$$c_{X,Y}=\mathrm{E}\left[(X-\mu_X)(Y-\mu_Y)\right] \tag{5.7.251}$$

Theorem 5.45. We have:

$$\left(c_{X,Y}\right)^2\leq \mathrm{V}(X)\mathrm{V}(Y) \tag{5.7.252}$$

We will prove this relation immediately because the use of the covariance alone for data analysis is not always great because it is not strictly limited and easy to use (at interpretation). We will construct an indicator easier to use in business.

Proof 5.45.1. We choose any constant a and we calculate the variance of:

$$aX+Y \tag{5.7.253}$$

We can then immediately write using the properties of the variance and the of the mean:

$$\mathrm{V}(aX+Y)=a^2\mathrm{V}(X)+\mathrm{V}(Y)+2ac_{X,Y} \tag{5.7.254}$$

The right quantity is positive or null for any a by construction of the variance (left). So the discriminant of the expression (see section Calculus page 1383), seen as a polynomial in a is of the type:

$$\begin{gathered}P(x)=ax^2+bx+c=a\left[\left(x+\frac{b}{2a}\right)^2-\frac{b^2-4ac}{4a^2}\right]\\ \Rightarrow\\ P(a)=\mathrm{V}(X)a^2+2c_{X,Y}a+\mathrm{V}(Y)=\mathrm{V}(X)\left[\left(a+\frac{2c_{X,Y}}{2\mathrm{V}(X)}\right)^2-\frac{(2c_{X,Y})^2-4\mathrm{V}(X)\mathrm{V}(Y)}{4\mathrm{V}(X)^2}\right]\end{gathered} \tag{5.7.255}$$

Because $P(a)$ is positive for any a we have as only possibility that:

$$(2c_{X,Y})^2-4\mathrm{V}(X)\mathrm{V}(Y)\leq 0 \tag{5.7.256}$$

Therefore after simplification:

$$\left(c_{X,Y}\right)^2\leq \mathrm{V}(X)\mathrm{V}(Y) \tag{5.7.257}$$

■ Q.E.D.

This gives us also:

$$\frac{(c_{X,Y})^2}{\mathrm{V}(X)\mathrm{V}(Y)}\leq 1\Leftrightarrow\frac{|c_{X,Y}|}{\sqrt{\mathrm{V}(X)\mathrm{V}(Y)}}\leq 1 \tag{5.7.258}$$

Finally we get some statistical inequality (it's a special form of the Cauchy-Schwarz inequality that we will prove later in the section of Vector Calculus page 1826):

$$-1 \leq \frac{c_{X,Y}}{\sqrt{\mathrm{V}(X)\mathrm{V}(Y)}} \leq 1 \tag{5.7.259}$$

If the variances of X and Y are non-zero, the correlation between X and Y is defined by the "linear correlation coefficient" (it is a standardized covariance so that its amplitude does not depend on the chosen unit measure) and written:

$$R_{X,Y} = \frac{c_{X,Y}}{\sqrt{\mathrm{V}(X)\mathrm{V}(Y)}} \tag{5.7.260}$$

and also named "product moment correlation coefficient" or simply "correlation coefficient".

Which can also be written in an expanded form (using Huygens theorem):

$$R_{X,Y} = \frac{\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)}{\sqrt{\mathrm{V}(X)\mathrm{V}(Y)}} = \frac{\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)}{\sqrt{\left(\mathrm{E}(X^2)-\mathrm{E}(X)^2\right)\left(\mathrm{E}(Y^2)-\mathrm{E}(Y)^2\right)}} \tag{5.7.261}$$

or more condensed:

$$\boxed{R_{X,Y} = \frac{c_{X,Y}}{\sigma_X\sigma_Y}} \tag{5.7.262}$$

Remark

Note that normally, the letter R is reserved to say that this is an estimator of the correlation coefficient but the definition above is not an estimator (the variances doesn't have the small hat...) and that, strictly speaking, we should then write $\rho_{X,Y}$ according to the traditions of use.

Whatever the units and the orders of magnitude, the correlation coefficient is a number between -1 and $+1$ without units (so its value does not depend on the unit of measure, which is by far not the case for all statistical indicators!). It reflects more or less the linear dependence of X and Y or geometrically more or less the flatness magnitude. We can therefore say that a coefficient of correlation of zero or close to 0 correlation means that there is no linear relation between the characters. But it does not involve any notion of more general independence!

So when the correlation is zero:

$$\rho_{X,Y} = \frac{c_{X,Y}}{\sigma_X\sigma_Y} = 0 \tag{5.7.263}$$

Then:

$$c_{X,Y} = \mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y) = 0 \tag{5.7.264}$$

Hence:

$$\mathrm{E}(XY) = \mathrm{E}(X)\mathrm{E}(Y) \tag{5.7.265}$$

And we know that this relations holds when random variables are independent. But think that in the general case "*uncorrelated*" means "*independence*" is totally wrong! Only independence implies uncorrelation! The opposite is not true (if X and Y are uncorrelated, then they can still be dependent)!

✍**Example:**

Consider as example of uncorrelated variables that are not independent, the following example given (useful example in finance!) by:

$$X = \mathcal{N}(0,1) \qquad Y = X^2 \tag{5.7.266}$$

Y is clearly dependent upon X. As we will prove later, during our study of the Normal centered reduced distribution, we have:

$$\mathrm{E}(X) = 0 \qquad \mathrm{E}(X^3) = 0 \tag{5.7.267}$$

And as:

$$c_{X,Y} = \mathrm{E}(XY) - \mathrm{E}(X)\mathrm{E}(Y) = \mathrm{E}(X \cdot X^2) - \mathrm{E}(X)\mathrm{E}(X) = 0 \tag{5.7.268}$$

Then we have indeed dependent variables that are uncorrelated!

The only general case when lack of correlation implies independence is when the joint distribution of X and Y is Gaussian!

The figure below illustrates some common cases and the last row highlights well situations with dependent but uncorrelated variables:

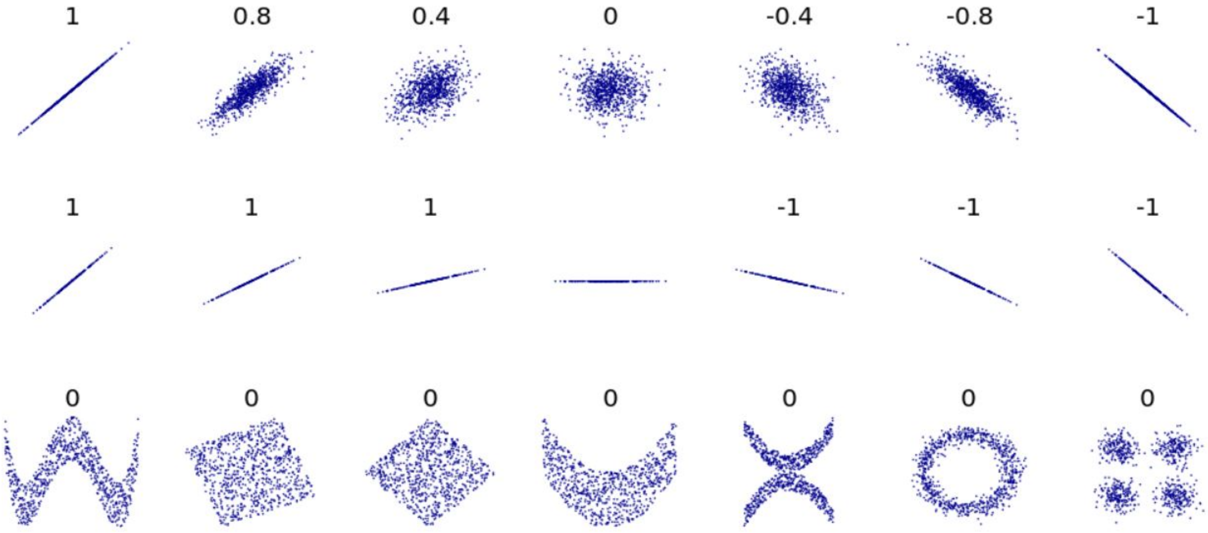

Figure 5.114: **Several sets of (x, y) points, with the corresponding Pearson correlation (source: Wikipedia, author: Denis Boigelot)**

When the correlation coefficient is near $+1$ or -1, the characters are said to be strongly correlated. We must be careful with the frequent confusion between correlation and causality. Thus, two phenomena that are correlated does not imply in any way that one is the cause of the other (this fallacy is also known as "spurious correlation" or "cum hoc ergo propter hoc[34]", latin for "with this, therefore because of this," and "false cause")!!!!

Indeed, for any two correlated events, A and B, the different possible relationships include:

- A causes B (direct causation);
- B causes A (reverse causation);
- A and B are consequences of a common cause, but do not cause each other;
- A causes B and B causes A (bidirectional or cyclic causation);
- A causes C which causes B (indirect causation);
- There is no connection between A and B;
- The correlation is a coincidence.

Remark

A situation in which a measure of association or relationship between exposure and outcome is distorted by the presence of another variable is named a "confounding". An extraneous variable that wholly or partially accounts for the observed effect is named a "confounder variable".

So we know that correlation doesn't imply necessarily causation and that in practice times we can't always have mathematical (i.e. statistical) evidence that the correlation implies a causation! However there is a consensus in the scientific field that a correlation implies a causation when the following so named "Braford Hill Criterion" are fulfilled[35]:

---

[34] *Post hoc ergo propter hoc* (latin of "after this, therefore because of this:) is an informal fallacy that states: "Since event Y followed event X, event Y must have been caused by event X." It is often shortened simply to *post hoc fallacy*. A logical fallacy of the questionable cause variety, it is subtly different from the fallacy *cum hoc ergo propter hoc* ("with this, therefore because of this"), in which two events occur simultaneously or the chronological ordering is insignificant or unknown. Post hoc is a logical fallacy in which an event says to be the cause of a later event because it occurred earlier!

[35] Keep in mind that a "systematic review" answers a defined research question by collecting and summarising all empirical evidence that fits pre-specified eligibility criteria. A "meta-analysis" is the use of statistical methods to summarise the results of these studies.

Criteria	Meaning
Strength of Association	A strong association is more likely to have a causal component than is a modest association. Strength of the association is determined by the types of existing studies. The highest-level studies from the evidence pyramid would represent the strongest associations, (i.e., Systematic Reviews with meta-analysis and RCTs). Results from these studies must demonstrate an Odds Ratio (OR) or Relative Risk (RR) of at least 2 or above in order to be meaningful. Anything between 1 and 2 is weak, while > 2 is moderate and > 4 is considered strong.
Consistency	A relationship is repeatedly observed in all available studies.
Specificity	A factor influences specifically a particular outcome or population. The more specific an association between a factor and an effect, the greater the probability that it is causal.
Temporality	The cause must precede the outcome it is assumed to affect (e.g. smoking before the appearance of lung cancer) when the outcome is measured over time (longitudinal study).
Biological Gradient (dose-response)	The outcome increases monotonically with increasing dose of exposure or according to a function predicted by a substantive theory (i.e. the more cigarettes one smokes, the greater the chance of the cancer occurring).
Plausability	The observed association can be plausibly explained by substantive matter, i.e., biologically possible.
Coherence	A causal conclusion should not fundamentally contradict present substantive knowledge (studies must not contradict each other).
Experiment	Causation is more likely if evidence is based on randomized experiments or a systematic review with a meta-analysis of randomized experiments. However, if RCT's are not ethically possible then prospective cohort studies may provide the highest level of evidence.
Analogy	For analogous exposures and outcomes, an effect has already been shown, e.g., effects first demonstrated on animals or an effect previously occurring on humans such as the effects of thalidomide on a foetus during pregnancy.

Table 5.39: **Bradford Hill correlation-causation criterion**

Coming back to the mathematical aspect of the correlation:

- If $R_{X,Y}=-1$ we are dealing with a "pure negative correlation" (in the case of a linear relation all measurement points are located on a straight line with a negative slope).
- If $-1<R_{X,Y}<+1$ we are dealing with a negative or positive correlation named "imperfect correlation" (in the case of a linear relation all measurement points are located on a straight line negative or positive slope respectively).

- If $R_{X,Y}=0$ the correlation is zero... (in the case of a linear relation all the measurement points are located on a straight line of slope zero).

- If $R_{X,Y}=+1$ we are dealing with a "pure positive correlation" (in the case of a linear relation all measurement points are located on a straight positive slope).

The analysis of the correlation coefficient has the objective of determining the degree of association between variables: it is often expressed as the coefficient of determination, which is the square of the correlation coefficient. The coefficient of determination thus measures the contribution of a variable to the explanation of the second. However, asking «*how high should R (or R^2) be?* doesn't make sense. A low R doesn't negate a significant predictor or change the meaning of its coefficient. R is simply whatever value it is, and it doesn't need to be any particular value to allow for a valid interpretation».

Using the expressions of mean and standard deviation of equiprobable variables as demonstrated above (thus the idea of computing the correlation of two random variables is a good idea if they are jointly gaussian), we start:

$$R_{X,Y}=\frac{\mathrm{E}(XY)-\mathrm{E}(X)\mathrm{E}(Y)}{\sqrt{(\mathrm{E}(X^2)-\mathrm{E}(X)^2)\,(\mathrm{E}(Y^2)-\mathrm{E}(Y)^2)}} \tag{5.7.269}$$

To obtain the estimator of the coefficient of correlation:

$$R_{X,Y}=\frac{\dfrac{1}{n}\sum_{i=1}^{n}x_iy_i-\left(\dfrac{1}{n}\sum_{i=1}^{n}x_i\right)\left(\dfrac{1}{n}\sum_{i=1}^{n}y_i\right)}{\sqrt{\left(\dfrac{1}{n}\sum_{i=1}^{n}x_i^2-\dfrac{1}{n^2}\left(\sum_{i=1}^{n}x_i\right)^2\right)\left(\dfrac{1}{n}\sum_{i=1}^{n}y_i^2-\dfrac{1}{n^2}\left(\sum_{i=1}^{n}y_i\right)^2\right)}} \tag{5.7.270}$$

where we see that the covariance becomes the average of the products minus the product of averages.

Thus after simplification we get a famous expression:

$$\boxed{R_{X,Y}=\frac{\sum_{i=1}^{n}x_iy_i-\dfrac{1}{n}\left(\sum_{i=1}^{n}x_i\right)\left(\sum_{i=1}^{n}y_i\right)}{\sqrt{\left(\sum_{i=1}^{n}x_i^2-\dfrac{1}{n}\left(\sum_{i=1}^{n}x_i\right)^2\right)\left(\sum_{i=1}^{n}y_i^2-\dfrac{1}{n}\left(\sum_{i=1}^{n}y_i\right)^2\right)}}} \tag{5.7.271}$$

The correlation coefficient can be calculated in the English version of Microsoft® Excel® 11.8346 and others with the integrated `CORREL( )` function.

We will see in the section of Numerical Methods a more general expression of the correlation coefficient (page 6332) and in the section of Statistical Mechanics an alternative indicator (page 3531).

Remarks

R1. In the literature, the experimental correlation coefficient is often named "sampling Pearson coefficient" (in the equiprobable case), or "Pearson product-moment", and when we carry it to the square, then we name it the "coefficient of determination".

R2. Often the square of the coefficient is somewhat improperly interpreted as the % of variation explained in the response variable Y by the explanatory variable X.

Finally, note that we have the following relation which is used a lot in practice (see the section Economics page 7698 for famous detailed examples!):

$$\text{V}(X+Y)=\text{V}(X)+\text{V}(Y)+2c_{X,Y}=\text{V}(X)+\text{V}(Y)+2R_{X,Y}\sqrt{\text{V}(X)\text{V}(Y)} \tag{5.7.272}$$

or the version with the standard deviation even more famous:

$$\boxed{\sigma_{X+Y}=\sqrt{\sigma_X^2+\sigma_Y^2+2R_{X,Y}\sigma_X\sigma_Y}} \tag{5.7.273}$$

It is a relation that we can often see in finance in the calculation of the VaR (Value at Risk) according to RiskMetrics methodology proposed by JP Morgan (see section Economy page 7859).

Let us see a small application example of the correlation but that has nothing to do with VaR (at least for the moment...).

✍**Example:**

An airline company has 120 seats available that she reserves for connecting passengers from two flights arrived earlier in the journey and that have to go to Frankfurt. The first flight arrived from Manila and the number of passengers on board follows a Normal distribution with mean 50 and variance 169. The second flight arrives in Taipei and the number of passengers on board follows a Normal distribution with mean 45 and variance 196.

The linear correlation coefficient between the number of passengers of both flights was measured as:

$$R_{X,Y}=0.5 \tag{5.7.274}$$

The law that follows the number of passengers for Frankfurt if we assume that the law of the couple also follows a Normal distribution (according to statement!) is:

$$X+Y=\mathcal{N}\left(\mu_Y+\mu_X,\sigma_{X+Y}\right) \tag{5.7.275}$$

with:

$$\begin{aligned}&\mu_Y+\mu_X=50+45=95\\&\sigma_{X+Y}=\sqrt{\sigma_X^2+\sigma_Y^2+2R_{X,Y}\sigma_X\sigma_Y}=\sqrt{169+196+2\cdot 0.5\sqrt{169\cdot 196}}\cong 23.38\end{aligned} \tag{5.7.276}$$

This is a bad start for customer satisfaction in the long term...

We have proved earlier that for a sum of independent and identically distributed random variables, the standard-deviation of their mean was given by the standard-error:

$$\sigma_{\bar{X}}=\frac{\sigma}{\sqrt{n}} \tag{5.7.277}$$

And what if their are not independent but still identically distributed of variance σ^2 (important case in Machine Learning but not only!)? First let us recall that:

$$\mathrm{V}\left(\sum_{i=1}^{n}X_i\right)=\sum_{i=1}^{n}\mathrm{V}(X_i)+2\sum_{i<j}^{n}\mathrm{cov}(X_i,X_j) \tag{5.7.278}$$

Therefore:

$$\mathrm{V}\left(\frac{1}{n}\sum_{i=1}^{n}X_i\right)=\mathrm{V}(\bar{X})=\frac{n\sigma^2}{n^2}+\frac{2\displaystyle\sum_{i<j}^{n}\mathrm{cov}(X_i,X_j)}{n^2} \tag{5.7.279}$$

Using the definition of correlation seen just above:

$$R_{X_i,Y_i}=\frac{\mathrm{cov}_{X_i,Y_i}}{\sigma_{X_i}\sigma_{Y_i}} \tag{5.7.280}$$

We get (keeping in mind that all variances are assumed to be the same such that $\sigma_{X_i}\sigma_{Y_i}=\sigma$):

$$\mathrm{V}(\bar{X})=\frac{n\sigma^2}{n^2}+\frac{2\displaystyle\sum_{i<j}^{n}R_{X_i,Y_i}\sigma^2}{n^2}=\frac{\sigma^2}{n}+\frac{2\sigma^2\sum_{i<j}^{n}R_{X_i,Y_i}}{n^2} \tag{5.7.281}$$

Let us now assume that all pairwise correlations are equals (such that $R_{X_i,Y_i}=R$), then we get:

$$\begin{aligned}\mathrm{V}(\bar{X})&=\frac{\sigma^2}{n}+\frac{2\sigma^2\displaystyle\sum_{i<j}^{n}R}{n^2}=\frac{\sigma^2}{n}+\frac{\sigma^2 n(n-1)R}{n^2}=\frac{\sigma^2}{n}+\frac{\sigma^2(n-1)R}{n}\\&=R\sigma^2+\frac{1-R}{n}\sigma^2\end{aligned} \tag{5.7.282}$$

That latter relation is often denoted by data scientists as following:

$$\mathrm{V}(\bar{X})=\rho\sigma^2+\frac{1-\rho}{B}\sigma^2 \tag{5.7.283}$$

Finally, let us recall that the variance-covariance matrix is given by:

$$\Sigma=\begin{bmatrix}\mathrm{V}_{11} & c_{12} & \cdots & c_{1n}\\ c_{21} & \mathrm{V}_{22} & \cdots & c_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ c_{n1} & c_{n2} & \cdots & \mathrm{V}_{nn}\end{bmatrix}=\begin{bmatrix}\sigma_{11}^2 & c_{12} & \cdots & c_{1n}\\ c_{21} & \sigma_{22}^2 & \cdots & c_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ c_{n1} & c_{n2} & \cdots & \sigma_{nn}^2\end{bmatrix} \tag{5.7.284}$$

Dividing each term by the corresponding terms $\sqrt{\text{V}_i}\sqrt{\text{V}_j}$ gives us the "correlation matrix":

$$R=\begin{bmatrix} \dfrac{\text{V}_{11}}{\sqrt{\text{V}_1}\sqrt{\text{V}_1}} & \dfrac{c_{12}}{\sqrt{\text{V}_1}\sqrt{\text{V}_2}} & \cdots & \dfrac{c_{1n}}{\sqrt{\text{V}_1}\sqrt{\text{V}_n}} \\ \dfrac{c_{21}}{\sqrt{\text{V}_2}\sqrt{\text{V}_1}} & \dfrac{\text{V}_{22}}{\sqrt{\text{V}_2}\sqrt{\text{V}_2}} & \cdots & \dfrac{c_{2n}}{\sqrt{\text{V}_2}\sqrt{\text{V}_n}} \\ \vdots & \vdots & \ddots & \vdots \\ \dfrac{c_{n1}}{\sqrt{\text{V}_n}\sqrt{\text{V}_1}} & \dfrac{c_{n2}}{\sqrt{\text{V}_n}\sqrt{\text{V}_2}} & \cdots & \dfrac{\text{V}_{nn}}{\sqrt{\text{V}_n}\sqrt{\text{V}_n}} \end{bmatrix}=\begin{bmatrix} 1 & R_{12} & \cdots & R_{1n} \\ R_{21} & 1 & \cdots & R_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ R_{n1} & R_{n2} & \cdots & 1 \end{bmatrix} \tag{5.7.285}$$

Notice that if the variances are all equal to the unit ($\text{V}_i=1$) then the covariance matrix is equal to the correlation matrix, i.e. $R=\Sigma$ (this is a useful property that we will use much later during our study of the variance inflation factor for multicollinearity detection)!

Let us see what we just said in another way! As we know the equation for the standardization of a variable is written as:

$$z=\frac{x_i-\bar{x}}{\sigma_x} \tag{5.7.286}$$

We also know that the original covariance matrix is defined as (using unbiased estimator):

$$\sigma_{xy}=\frac{1}{n-1}\sum_i^n(x_i-\bar{x})(y_i-\bar{y}) \tag{5.7.287}$$

And after standardizing both variables:

$$x'=\frac{x-\bar{x}}{\sigma_x} \qquad \text{and} \qquad y'=\frac{y-\bar{y}}{\sigma_y} \tag{5.7.288}$$

we get:

$$\begin{aligned}\sigma'_{xy}&=\frac{1}{n-1}\sum_i^n(x'_i-0)(y'_i-0)=\frac{1}{n-1}\sum_i^n\left(\frac{x-\bar{x}}{\sigma_x}\right)\left(\frac{y-\bar{y}}{\sigma_y}\right)\\&=\frac{1}{(n-1)\cdot\sigma_x\sigma_y}\sum_i^n(x_i-\bar{x})(y_i-\bar{y})=\frac{\sigma_{xy}}{\sigma_x\sigma_y}\end{aligned} \tag{5.7.289}$$

So finally:

$$\sigma'_{xy}=\frac{\sigma_{xy}}{\sigma_x\sigma_y} \tag{5.7.290}$$

So the variance-covariance matrix becomes indeed the correlation matrix with standardized variables!

5.7.3.1.4.1 Geometric interpretation

A measure of the relationship between two random variables is the covariance as we know given by:

$$c_{X,Y} = \mathrm{E}\left[(X-\mu_X)(Y-\mu_Y)\right] \tag{5.7.291}$$

Covariance normalized to unity is the correlation coefficient as we have just seen it:

$$\rho_{X,Y} = \frac{c_{X,Y}}{\sigma_X \sigma_Y} = \frac{\mathrm{E}\left[(X-\mu_X)(Y-\mu_Y)\right]}{\sqrt{\mathrm{E}[(X-\mu_X)^2]}\sqrt{\mathrm{E}[(Y-\mu_Y)^2]}} \tag{5.7.292}$$

Hence:

$$\rho_{X,Y} = \frac{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}[(X_i-\bar{x})(Y_i-\bar{y})]}{\sqrt{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(X_i-\bar{x})^2}\sqrt{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(Y_i-\bar{y})^2}} = \frac{\displaystyle\sum_{i=1}^{n}[(X_i-\bar{x})(Y_i-\bar{y})]}{\sqrt{\displaystyle\sum_{i=1}^{n}(X_i-\bar{x})^2}\sqrt{\displaystyle\sum_{i=1}^{n}(Y_i-\bar{y})^2}} \tag{5.7.293}$$

The resulting expression:

$$\rho_{X,Y} = \frac{\displaystyle\sum_{i=1}^{n}[(X_i-\bar{x})(Y_i-\bar{y})]}{\sqrt{\displaystyle\sum_{i=1}^{n}(X_i-\bar{x})^2}\sqrt{\displaystyle\sum_{i=1}^{n}(Y_i-\bar{y})^2}} \tag{5.7.294}$$

is the ratio of two elements. The numerator is the scalar product of two vectors, while the denominator is the product of their lengths:

$$\rho_{X,Y} = \frac{\displaystyle\sum_{i=1}^{n}[(X_i-\bar{x})(Y_i-\bar{y})]}{\sqrt{\displaystyle\sum_{i=1}^{n}(X_i-\bar{x})^2}\sqrt{\displaystyle\sum_{i=1}^{n}(Y_i-\bar{y})^2}} = \frac{\vec{x}\circ\vec{y}}{\|\vec{x}\|\cdot\|\vec{y}\|} = \cos(\vec{x},\vec{y})) \tag{5.7.295}$$

This expression shows the formal identity between the correlation coefficient, and the cosine of the angle between two random vectors.

5.7.3.1.4.2 Point biserial correlation coefficient

A "point-biserial correlation", denoted r_{pb}, is used to measure the strength and direction of the association that exists between one continuous variable and one dichotomous variable. It is a special case of the Pearson's product-moment correlation, which is applied when you have two continuous variables, whereas in this case one of the variables is measured on a dichotomous scale.

For example, we could use a point-biserial correlation to determine whether there is an association between salaries, measured in US dollars, and gender (i.e., your continuous variable would be "salary" and your dichotomous variable would be "gender", which has two categories: "males" and "females").

To calculate r_{pb} we assume that the dichotomous variable Y has the two values 0 and 1. If we divide the data set into two groups, group 1 which received the value "1" on Y and group 2 which received the value "0" on Y, then the point-biserial correlation coefficient is calculated as follows:

$$\boxed{r_{\text{pb}} = \frac{\mu_1 - \mu_0}{\sigma_n}\sqrt{\frac{n_1 n_0}{n^2}}} \tag{5.7.296}$$

where σ_n is the standard deviation used when data are available for every member of the population (obviously there are version that use the estimator of the standard deviation instead of the biased standard deviation!):

$$\sigma_n = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(X_i - \overline{X})^2} \tag{5.7.297}$$

μ_1 being the mean value on the continuous variable X for all data points in group 1, and μ_0 the mean value on the continuous variable X for all data points in group 2. Further, n_1 is the number of data points in group 1, n_0 is the number of data points in group 2 and n is the total sample size.

Proof 5.45.2. Let the n data consist of $n_0 > 0 (x, 0)$ pairs and $n_1 > 0 (x, 1)$ pairs. Their Pearson correlation coefficient will be the same as the reversed data consisting of corresponding $(0, x)$ and $(1, x)$ pairs. Because there are exactly two distinct values of the first coordinates, the regression line of the reversed data must pass through the mean points $(0, \mu_0)$ and $(1, \mu_1)$, whence it has slope:

$$a = \frac{\mu_1 - \mu_0}{1 - 0} = \mu_1 - \mu_0 \tag{5.7.298}$$

We have proved (see section Numerical Methods page 6332) that the correlation coefficient for a univariate regression is also given by:

$$R_{X,Y}^2 = \frac{a^2 \text{V}(X)}{\text{V}(Y)} \Leftrightarrow R_{X,Y} = \frac{a}{\sigma_Y}\sigma_X \tag{5.7.299}$$

Therefore the slope must be multiplied by the standard deviation of the first coordinates and divided by the standard deviation of the second coordinates (the original x values), denoted traditionally (sadly) by $\hat{\sigma}_n$. The standard deviation of the first coordinates is readily computed from the fact that they consist of n_0 zeros (0) and n_1 ones (1). Considering this set of values as a Bernoulli random variable, we have proved earlier above during our study of the Bernoulli distribution that:

$$\sigma_X = \sqrt{pq} = \sqrt{p(1-p)} \tag{5.7.300}$$

Therefore:

$$\sigma_X = \sqrt{pq} = \sqrt{\frac{n_0}{n}\frac{n_1}{n}} = \sqrt{\frac{n_0 n_1}{n^2}} \tag{5.7.301}$$

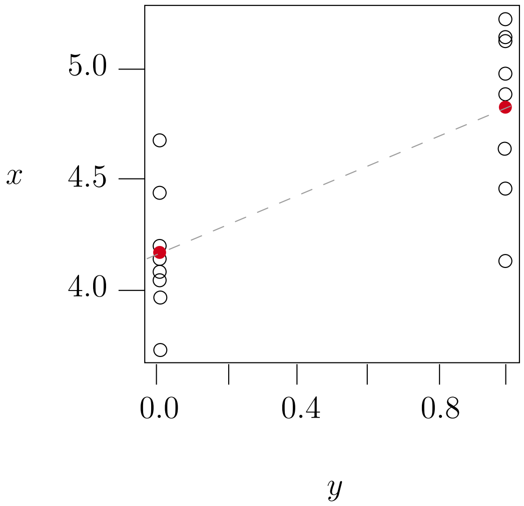
Consequently the point biserial Pearson correlation coefficient is:

$$r_{\text{pb}}=\frac{\mu_1-\mu_0}{\sigma_n}\sqrt{p(1-p)}=\frac{\mu_1-\mu_0}{\sigma_n}\sqrt{\frac{n_0n_1}{n^2}} \tag{5.7.302}$$

So the point biserial correlation coefficient is just a special case of the Pearson correlation coefficient. However remember that in most statistical computer softwares the Pearson correlation coefficient is calculated using the unbiased variance and the Point biserial correlation coefficient used the biased one, this is why we don't get the same numerical results when using both corresponding functions in softwares!

■ Q.E.D.

The idea is depicted here:



The heights of the red dots depict the mean values μ_0 and μ_1 of each vertical strip of points. The dashed gray line is the regression line.

Remark

R software native function computes the point biserial correlation coefficient with the corr and corr.test function because the point-biserial correlation is simply a special case of Pearson's product-moment correlation, which is applied when you have two continuous variables, whereas in this case one of the variables is measured on a dichotomous scale. But its also available as biserial.cor in various packages.

✍**Example:**

Let us imagine that the level of operational risk in an institution's business lines is graded as high or low based on the opinion of an operational risk analyst. Suppose we are interested in assessing the degree of correlation between operational risk and gross income of the business lines. Since in this case operational risk is a binary variable and gross income a continuous variable, we can use the biserial coefficient to estimate correlation!

5.7.3.1.4.3 Partial correlation and semipartial correlation

Partial correlation measures the degree of association between two random variables, with the effect of a set of controlling random variables removed. If we are interested in finding whether or to what extent there is a numerical relationship between two variables of interest, using their correlation coefficient will give misleading results if there is another, "confounding", variable that is numerically related to both variables of interest. This misleading information can be avoided by controlling (i.e. cancelling) for the confounding variable, which is done by computing the partial correlation coefficient.

When in the case of three variables we want to control (cancel) one of the variable and that this one is the unique that is qualitative, the strategy is then simple as it consist to calculate the correlation between the two remaining variable for each level of the qualitative variable. But things start to be more complicated when the variable to control (cancel) is continuous. This is why we need to build a more sophisticated approach!

The "partial correlation coefficient", denoted here $R_{AB.C}$, makes it possible to know the value of the correlation between two variables A and B, if the variable C had remained constant for the series of observations considered.

In other words, the partial correlation coefficient $R_{AB.C}$ is the total correlation coefficient between variables A and B when their best linear explanation has been removed in terms of C. It is given by the relation (in the obvious special case of three variables!):

$$\boxed{R_{AB.C}=\frac{R_{AB}-R_{AC}R_{BC}}{\sqrt{1-R_{AC}^2}\sqrt{1-R_{BC}^2}}} \tag{5.7.303}$$

The quickest proof of this relation is to rely on the geometric interpretation of the correlation (cosine).

But notice before that like the correlation coefficient, the partial correlation coefficient takes on a value in the range from -1 to $+1$. The value -1 conveys a perfect negative correlation controlling for some variables (that is, an exact linear relationship in which higher values of one variable are associated with lower values of the other); the value $+1$ conveys a perfect positive linear relationship, and the value 0 conveys that there is no linear relationship.

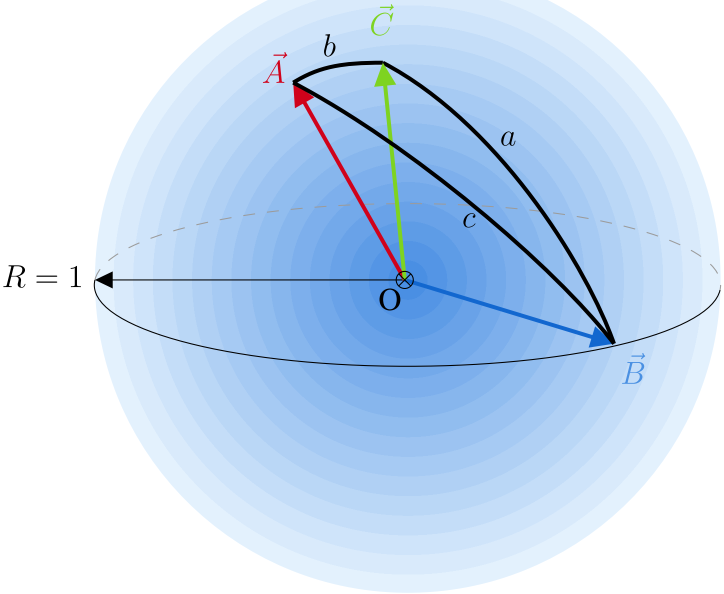
Also notice that if R_{AC} and R_{BC} are both equal to zero (i.e. there is no confounding variable) then we have the equality:

$$R_{AB.C}=\frac{R_{AB}-0\cdot 0}{\sqrt{1-0}\sqrt{1-0}}=R_{AB} \tag{5.7.304}$$

So it is easy to understand that in general when there is somewhere a correlation between some of the variables, then $R_{AB.C}>R_{AB}$. For other configuration values, the reader must be very precautions on the interpretation as the result depends obviously on the value of R_{AB}!

Ok now let's go for the proof in the special case of three variables!

The series of observations A, B and C, once centered reduced (thus of radius 1), are centered vectors $\vec{A}$, $\vec{B}$, $\vec{C}$ of unit length on the same sphere:



Their extremities (vertices) determine a spherical triangle ABC, whose sides a, b and c are the arcs of large circles $\overset{\frown}{BC}$, $\overset{\frown}{AC}$ and $\overset{\frown}{AB}$. The correlation coefficients between these vectors are (let us recall that for a unitary circle/sphere we have $\cos(\alpha) = \cos(a)$ as seen in the section of Trigonometry):

$$R_{BC} = \cos(a) \qquad R_{AC} = \cos(b) \qquad R_{AB} = \cos(c) \tag{5.7.305}$$

We have then by the cosine formula of the spherical triangles (see section Trigonometry page 2544) the following value for the opening angle of C:

$$\cos(\hat{C}) = \frac{\cos(c) - \cos(a)\cos(b)}{\sin(a)\sin(b)} = \frac{\cos(c) - \cos(a)\cos(b)}{\sqrt{1-\cos^2(a)}\sqrt{1-\cos^2(b)}} \tag{5.7.306}$$

Just as c is the angle between the points A and B (and on a unite sphere also the arclength $\overset{\frown}{AB}$), seen from the center of the sphere, $\hat{C}$ is the spherical angle between points A and B, seen from point C to the surface of the sphere, and:

$$R_{AB.C} = \cos(\hat{C}) \tag{5.7.307}$$

is the "partial correlation" between A and B when C is fixed.

Remarks

R1. If we partial one variable out of a correlation, that partial correlation is named a "first order partial correlation". If we partial out 2 variables from that correlation (e.g., $R_{12.34}$), we have a "second order partial correlation", and so forth. It is customary to refer to "unpartialed (raw, as it were) correlations" as "zero order correlations".

R2. Keep in mind that as for the correlation, the partial correlation when high, doesn't necessarily imply causation!

With partial correlation, we find the correlation between A and B holding C constant for both A and B. Sometimes, however, we want to hold C constant for just A or just B. In that case, we compute a "semipartial correlation coefficient".

Let's compare the correlational formulas for the partial and semipartial:

- Partial:

$$R_{AB.C}=\frac{R_{AB}-R_{AC}R_{BC}}{\sqrt{1-R_{AC}^2}\sqrt{1-R_{BC}^2}} \tag{5.7.308}$$

- Semipartial:

$$R_{A(B.C)}=\frac{R_{AB}-R_{AC}R_{BC}}{\sqrt{1-R_{BC}^2}} \quad \text{and} \quad R_{B(A.C)}=\frac{R_{AB}-R_{AC}R_{BC}}{\sqrt{1-R_{AC}^2}} \tag{5.7.309}$$

Note that the partial and semipartial correlation formulas are the same in the numerator and almost the same in the denominator. The partial contains something extra, that is, something missing from the semipartial correlation in the denominator. This means that the partial correlation is going to be larger in absolute value than the semipartial. This will be true except when the controlling or partialling variable is uncorrelated with the variable to be controlled or residualized; this is a trivial case.

5.7.3.1.4.4 Intraclass coefficient of correlation

The "intraclass correlation coefficient", denoted ICC, is a metric that can be used when quantitative measurements are made on measures that are organized into groups. It describes how the measurements of the same group are similar (thus it is still one of the many indicators of the family of repeatability and reproducibility studies like Cohen's kappa of approval that we will introduce later). This statistic is considered as a type of correlation and, unlike most other correlation measures, it therefore works on data structured in groups.

An important application is the evaluation of the consistency or the reproducibility of quantitative measurements made by different observers measuring the same quantity (R&R Gage studies - GRR). For example, if several doctors are asked to mark the results of a scan for signs of cancer progression, we may wonder how the scores are consistent from one physician to another (i.e. ANOVA with random factors).

An important aspect of this statistic (and also a weakness) is that it quantifies both inter-observer variability and intra-observer variability. Inter-observer variability refers to systematic differences between observers - for example, a physician may always mark patients at a higher risk level than other physicians. Intra-observer variability refers to measurement deviations of a single observer.

> **Remark**
>
> Since the intraclass correlation coefficient gives a composition of inter- and intra-observer variability, its results are sometimes considered difficult to interpret when observers are not exchangeable (random). Alternative measures such as the Cohen approval kappa statistic (see below), the Fleiss kappa and the correlation coefficient of concordance were proposed as more appropriate measures of agreement between non-exchangeable observers.

There are several kinds of intraclass correlations. They relate to different ways of conceptualizing the variables that are often referred to generically as "subjects" and "judges." Either of these variables may be a random variable (their levels were chosen at random from a population of possible levels) or a fixed variable, the different levels of which were specifically selected for this design, and the same levels would be selected again in a replication. In addition, we could use individual ratings, or we could take the mean of a set of ratings by different raters. Doing so will alter the intraclass correlation coefficient by providing a more reliable measure.

Here is a figurative example of a ICC (for numerical application see the Minitab or `R` companion books):

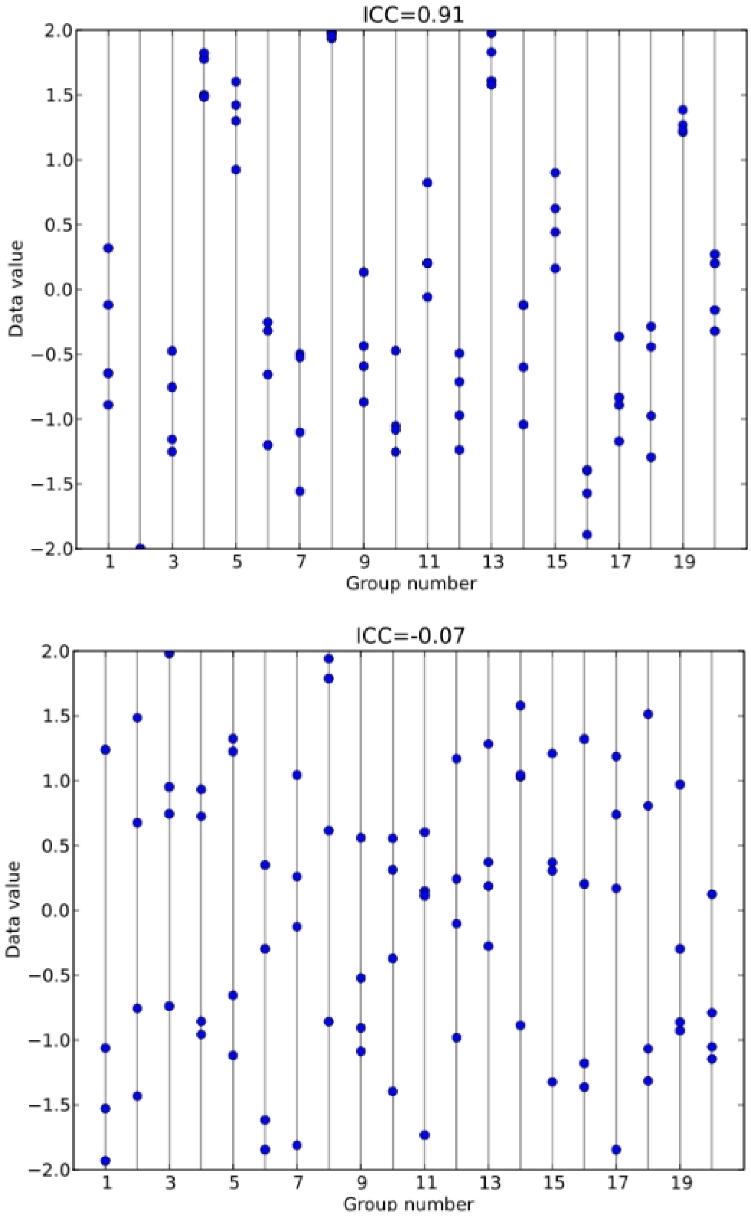


Figure 5.115: **Intra-class correlation coefficient illustration (source: Wikipedia)**

The intra-class correlation coefficient that will interest us here, denoted ICC1, that is most often used in practice is to consider a fixed factor (non-random) and the other random (there are therefore other variants that must be applied with caution!).

Indeed, imagine a study concerning the productivity of employees of a large company. The management committee wants to have an idea of the daily production and how it depends on the production machines used by the employees. If we take for the study a random sample of n employees among N, with all the machines at a quantity of k then we have a model with one fixed factor (machines) and the other one that is random (employees).

The empirical idea is then to write the model in the following very specific form (for the other more general models it will be necessary to wait until we write the developments!):

$$y_{ij}=\mu+\alpha_j+\varepsilon_{ij} \tag{5.7.310}$$

where i is the measure of the fixed factor (often as rows in ICC analysis tables) and j is the random factor represented by the judges (often as columns in ICC analysis tables) and thus ε_{ij} describes the variability of measurement of the elements in a given level of random factor and the error of the judges is inseparable from the element measured. The previous relation is also sometimes denoted:

$$y_{ij} = \mu_j + \varepsilon_{ij} \tag{5.7.311}$$

where obviously $\mu_j = \mu + \tau_j$.

As usual (...) we assume that:

$$\begin{aligned} \alpha_j &= \mathcal{N}(0, \sigma_\alpha^2) \\ \varepsilon_{ij} &= \mathcal{N}(0, \sigma_\varepsilon^2) \end{aligned} \tag{5.7.312}$$

So the variances of the α_j are assumed to be identical (which is nevertheless quite a strong hypothesis in practice!).

We have, therefore, from the linearity of the mean:

$$\text{E}(y_{ij}) = \text{E}(\mu + \alpha_j + \varepsilon_{ij}) = \mu \tag{5.7.313}$$

The decomposition of the variance is immediate if the errors are independent of the random factors:

$$\text{V}(y_{ij}) = \text{V}(\mu + \alpha_j + \varepsilon_{ij}) = \text{V}(\alpha_j) + \text{V}(\varepsilon_{ij}) = \sigma_\alpha^2 + \sigma_\varepsilon^2 \tag{5.7.314}$$

We have therefore:

$$y_{ij} = \mathcal{N}(\mu, \sigma_\alpha^2 + \sigma_\varepsilon^2) \tag{5.7.315}$$

For two elements (observations) taken under the same level of factor i, we have:

$$\begin{aligned} \text{cov}(y_{ij}, y_{ik}) &= \text{cov}(\mu + \alpha_j + \varepsilon_i j, \mu + \alpha_k + \varepsilon_{ik}) \\ &= \text{cov}(\alpha_j + \varepsilon_{ij}, \alpha_k + \varepsilon_{ik}) = \text{cov}(\alpha_j + \varepsilon_{ij}, \alpha_k) + \text{cov}(\alpha_j + \varepsilon_{ij}, \varepsilon_{ik}) \\ &= \text{cov}(\alpha_j, \alpha_k) + \text{cov}(\varepsilon_{ij}, \alpha_k) + \text{cov}(\alpha_j, \varepsilon_{ik}) + \text{cov}(\varepsilon_{ij}, \varepsilon_{ik}) \end{aligned} \tag{5.7.316}$$

But as the variances of all α_j are assumed to be identical and the errors independent of the fixed effects, the latter reduce to:

$$\text{cov}(y_{ij}, y_{ik}) = \text{cov}(\alpha_j, \alpha_k) = \text{cov}(\alpha_j, \alpha_j) = \text{V}(\alpha_j) = \sigma_\alpha^2 \tag{5.7.317}$$

And their correlation is then:

$$\boxed{\rho(y_{ij}, y_{ik}) = \frac{\text{cov}(y_{ij}, y_{ik})}{\text{V}(y_{ij})\text{V}(y_{ik})} = \frac{\sigma_\alpha^2}{\sigma_\alpha^2 + \sigma_\varepsilon^2}} \tag{5.7.318}$$

This is often denoted in textbooks as:

$$\text{ICC} = \frac{S_b^2}{S_b^2 + S_w^2} \tag{5.7.319}$$

Where S_w^2 is the pooled variance (see page 1011) within subjects, and S_b^2 is the variance of the measurements between subjects. $S_b^2+S_w^2$ is the total variance.

It is therefore the ratio of the variance of the random factors to the total variance (the denominator including the variance of the error) which is often denoted ICC1 or ICC(1,1) to say that it is the Intraclass correlation coefficient for 1 random factor and 1 fixed factor.

So if $\sigma_\varepsilon\rightarrow 0$, the intraclass correlation is unitary and this is then and indicator of good reproducibility!

Let us now recall from our study of one fixed factor ANOVA (page 1004) that we had the following decomposition in sum of the squares:

$$\begin{array}{ccccc} Q_T & = & Q_A & + & Q_R \\ \sum_{ij}(y_{ij}-\bar{\bar{y}})^2 & = & \sum_i n_i(\bar{y}_i-\bar{\bar{y}})^2 & + & \sum_{ij}(y_{ij}-\bar{y}_i)^2 \end{array} \tag{5.7.320}$$

If $n_i=n$ (balanced experiment), then we have obviously:

$$\begin{array}{ccccc} Q_T & = & Q_A & + & Q_R \\ \sum_{ij}(y_{ij}-\bar{\bar{y}})^2 & = & n\sum_i(\bar{y}_i-\bar{\bar{y}})^2 & + & \sum_{ij}(y_{ij}-\bar{y}_i)^2 \end{array} \tag{5.7.321}$$

This is often written in the context of the use of the intra-class correlation coefficient:

$$\frac{\sum_{ij}(y_{ij}-\bar{\bar{y}})^2}{N-1}=n\frac{\sum_i(\bar{y}_i-\bar{\bar{y}})^2}{k-1}+\frac{\sum_{ij}(y_{ij}-\bar{y}_i)^2}{k(n-1)}=n\sigma_\alpha^2+\sigma_\varepsilon^2 \tag{5.7.322}$$

where for recall $N=kn$. Here we assume therefore that the judges are indexed by i, the observations by j and that we have n judges and k observations!

And we also regularly have the following notations in some textbooks:

$$\text{MS}_{\text{w/intra}}=\sigma_\varepsilon^2 \qquad \text{and} \qquad \text{MS}_{\text{b/inter}}=n\sigma_\alpha^2+\sigma_\varepsilon^2 \tag{5.7.323}$$

or:

$$\text{SSW}=\sigma_\varepsilon^2 \qquad \text{and} \qquad \text{SSB}=n\sigma_\alpha^2+\sigma_\varepsilon^2 \tag{5.7.324}$$

where SSW stands for "Sum of Squares Within" and SSB for "Sum of Squares Between" or (...):

$$\text{MSE}=\sigma_\varepsilon^2 \qquad \text{and} \qquad \text{MSk}=n\sigma_\alpha^2+\sigma_\varepsilon^2 \tag{5.7.325}$$

where MSE stands for "Mean Square for Error" and MSk for "Mean Square for treatments". Therefore:

$$n\sigma_\alpha^2=\text{MS}_{\text{b/inter}}-\sigma_\varepsilon^2=\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}} \tag{5.7.326}$$

Hence:

$$\sigma_\alpha^2=\frac{\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}}}{n} \tag{5.7.327}$$

Remark

As the reader have maybe notice it, the numerator may be negative and therefore so may be σ_α^2... If we get negative variance components, the following are possible ways to deal with the negative estimates:

- Accept the estimate as evidence of a true value of zero and use zero as the estimate, recognizing that the estimator will no longer be unbiased.
- Retain the negative estimate, recognizing that subsequent calculations using the results might not make much sense.
- Interpret that the negative component estimate indicates an incorrect statistical model.
- Collect more data and analyse them separately or in conjunction with the existing data and hope that increased information will yield positive estimates.

For example, when a variance component estimate is less than zero, the software Minitab displays the negative estimate, but sets the estimate to zero in order to calculate the percent of total variability.

This is the reasons why we often find the intraclass correlation coefficient in the following common form in the textbooks because it allows a sometimes a more intuitive approach to the concept:

$$\begin{aligned}\text{ICC} &= \frac{\sigma_\alpha^2}{\sigma_\alpha^2+\sigma_\varepsilon^2} = \frac{\dfrac{\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}}}{n}}{\dfrac{\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}}}{n}-\text{MS}_{\text{w/intra}}} = \frac{\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}}}{\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}}+n\text{MS}_{\text{w/intra}}}\\ &= \frac{\text{MS}_{\text{b/inter}}-\text{MS}_{\text{w/intra}}}{\text{MS}_{\text{b/inter}}-(n-1)\text{MS}_{\text{w/intra}}}\end{aligned} \tag{5.7.328}$$

That is also often written is some textbooks as:

$$\text{ICC} = \frac{\text{MS}_{\text{bet S}}-\text{MS}_{\text{residual}}}{\text{MS}_{\text{bet S}}+(n-1)\text{MS}_{\text{residual}}} \tag{5.7.329}$$

Dominic V. Cicchetti (11994 according to holocene calendar) gives the following often quoted guidelines for interpretation for kappa or ICC inter-rater agreement measures:

ICC value	Criteria
$0.4 <$	Poor
$[0.4, 0.59]$	Fair
$[0.60, 0.74]$	Good
> 0.74	Excellent

Table 5.40: Interpretation for kappa or ICC inter-rater agreement

5.7.3.2 Continuous Variables and Moments

Definitions (#5.7.131):

D1. We say that X is a continuous variable if its "cumulative distribution function" (C.D.F.) is continuous (already defined above). The distribution function of X is defined by for $x \in \mathbb{R}$ or a truncated subset of $\mathbb{R}$:

$$F(x) = P(X \leq x) \tag{5.7.330}$$

that is the cumulative probability that the random variable X is smaller than or equal to the set value x. More properly, as for discrete variables, this is denoted by:

$$F_X(t) = P(X \leq t) = P(X \in]\min(D), t]) \qquad \forall t \in \mathbb{R} \tag{5.7.331}$$

with:

$$0 \leq P(X) \leq 1 \quad \text{and} \quad 0 \leq F(X) \leq 1 \tag{5.7.332}$$

D2. We denote by:

$$G(x) = 1 - F(x) = P(X > x) \tag{5.7.333}$$

the "survival function" or "tail function".

D3. If furthermore the distribution function F of X is continuously differentiable of derivative f (or sometimes denoted by ρ) named "probability density function[36]" or just simply "distribution function" then we say that X is absolutely continuous and in this case we have:

$$P(x_1 \leq X \leq x_2) = \int\limits_{x_1}^{x_2} f(x)\mathrm{d}x = F(x_2) - F(x_1) \tag{5.7.334}$$

with the normalization condition:

$$P(X < -\infty) = \int\limits_{-\infty}^{+\infty} f(x)\mathrm{d}x = \int\limits_{-\infty}^{+\infty} \mathrm{d}F(x) = 1 \tag{5.7.335}$$

Any probability distribution function must satisfy the integral of normalization in its domain of definition!

Let us consider a typical transformation of random variables that is quite common to generalize some special cases to more generic cases (typically from the standard Normal law to the general Normal law or from the standard Cauchy law to the generalized Cauchy law)! Let X be a continuous random variable be then set $Y = a + bX$ where a is named the "location parameter" and with $b > 0$ named the "scale parameter" and let us denote F the distribution function of X and G the distribution function of Y. Then:

---

[36] Keep in mind that the expression "probability mass function" is reserved to discrete variables.

$$G(y) = P(Y \leq y) = P(a + bX \leq y) = P\left(X \leq \frac{y-a}{b}\right) = F\left(\frac{y-a}{b}\right) \tag{5.7.336}$$

Now we differentiate and we get the important and trivial result:

$$g(y) = f\left(\frac{y-a}{b}\right)\frac{1}{b} \tag{5.7.337}$$

where g is the density function for Y and f is the density function for X.

We can also consider the case where $b < 0$. Then:

$$G(y) = P(Y \leq y) = P(a - bX \leq y) = P\left(X \geq \frac{y-a}{b}\right) = 1 - F\left(\frac{y-a}{b}\right) \tag{5.7.338}$$

differentiating:

$$g(y) = -f\left(\frac{y-a}{b}\right)\frac{1}{b} = f\left(\frac{y-a}{b}\right)\frac{1}{|b|} \tag{5.7.339}$$

They reader must try to keep in mind these relations if possible.

Remark

It is interesting to note that the definition implies that the probability that a completely continuous random variable takes a given value tends to zero! So it is not because an event has almost a zero probability that it can not happen!!!

The average being defined by a sum weighted by probabilities for a discrete variable, it becomes an integral for a continuous variable (the upper and lower integration limits are not always from $-\infty$ to $+\infty$ obviously! It depends of the definition domain of the random variable of interest):

$$\boxed{\mathrm{E}(X) = \int_{-\infty}^{+\infty} x f(x)\mathrm{d}x} \tag{5.7.340}$$

and therefore the variance for a continuous variable: is written as:

$$\boxed{\mathrm{V}(X) = \int_{-\infty}^{+\infty} [x - \mathrm{E}(X)]^2 f(x)\mathrm{d}x} \tag{5.7.341}$$

Then we have also the median that is logically redefined in the case of a continuous random variable by:

$$\boxed{P(X \leq M_e) = P(X \geq M_e) = \int_{-\infty}^{M_e} f(x)\mathrm{d}x = \int_{M_e}^{+\infty} f(x)\mathrm{d}x = \frac{1}{2}} \tag{5.7.342}$$

and it rarely coincides with the average!

And the modal value is given by the value of x where:

$$\frac{\mathrm{d}f(x)}{\mathrm{d}x}=0 \tag{5.7.343}$$

Statisticians often use the following notations for the expected mean of a continuous variable:

$$\mathrm{E}(X), M(X), \mu_X, \mu \tag{5.7.344}$$

and for the variance:

$$\mathrm{V}(X), S(X), \sigma_X^2, \sigma^2 \tag{5.7.345}$$

That is the same as for the moment of discrete variable.

Thereafter, we will calculate these different moments indicators with detailed proofs only for the most used cases.

But before... let us discuss about some other well-knows moments and highly discussed...!

5.7.3.2.1 Skewness and Kurtosis

Caution! I have hesitated during many years (more than 10 years!) to write something about the skewness and kurtosis in this textbook as they are most of time misleading concepts and that they are difficult (or even impossible...) to introduce with mathematical rigour. I changed my mind when I saw that my students were expecting something more complete and robust than Wikipedia. The reader must keep in mind that these both indicators must be use with caution and are good tools if we know that we are working with Normally distributed data.

As already mentioned in the previous warning, skewness and kurtosis are somewhat vague notions. The reader should therefore not expect any proof of their origin here... Furthermore, the concept of "symmetry", is mathematically precise, but skewness by contrast is surprisingly slippery. Kurtosis is perhaps even more so.

The underlying ideas corresponding definitions are the following (the definitions are given for discrete variable but can easily be extend to continuous variable by converting the sums into integrals!):

Definitions (#5.7.132):

D1. If the "skewness", denoted in general γ, and associated most of time with the moment of order 3 also named the "Fisher-Pearson coefficient of skewness":

$$\boxed{\gamma_1=\frac{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^3}{\left(\sqrt{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^2}\right)^3}} \qquad (5.7.346)$$

is zero, the distribution is symmetric (this does not mean that the symmetry takes place on a peak of the distribution because in the bimodal case the axis of symmetry may be between the two symmetric modal values). If the skewness is positive (right-modal), the distribution (modal / median value) is lean to the right (or there are extreme values to the right). If the skewness is negative (left-modal), the distribution (the modal / median value) is leaned to the left (or there are extreme values to the left).

Remark

A common question is why the skewness is defined as third central moment, and not fifth or any other number? What's the logic behind it? In fact nothing special! We could choose any odd power but the thing is that the moment of order 1 is the expected mean (already taken...) and the next smallest order easy to manage for further calculations is the power of 3 (we let the reader imagine the integration of distribution function with variables of order like 5 or bigger...).

It's possible for a distribution to be symmetric but not have zero third moment. A simple counterexample is any T-distribution with 3 or fewer degrees of freedom (see proof during our study of the corresponding distribution). In samples, however, symmetry implies zero third moment - but samples are almost never perfectly symmetric, so it's not much use there either. It's also possible to build asymmetric distributions that have non-zero third moment (see our `R` companion book!)!!! So symmetry doesn't necessarily imply zero third moment and zero third moment doesn't necessarily imply symmetry.

D2. If the "kurtosis", denoted in general κ (see the maths just after the definitions), and associated most of time with the moment of order 4 (hence always positive or equal to zero):

$$\boxed{\kappa_1=\frac{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^4}{\left(\sqrt{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^2}\right)^4}} \tag{5.7.347}$$

and if we define the "excess kurtosis" as κ_1-3. There are three distinct regimes as described below:

- The excess kurtosis is zero, i.e. "mesokurtic", then the flattening is similar to that of a Normal distribution[37].
- If the value is greater than zero, i.e. "leptokurtic", then the distribution of interest is higher than that of a Normal distribution with equal mean.
- The excess kurtosis is smaller than zero, i.e. "platikurtic", then the distribution of interest is lower than that of a Normal distribution with equal mean.

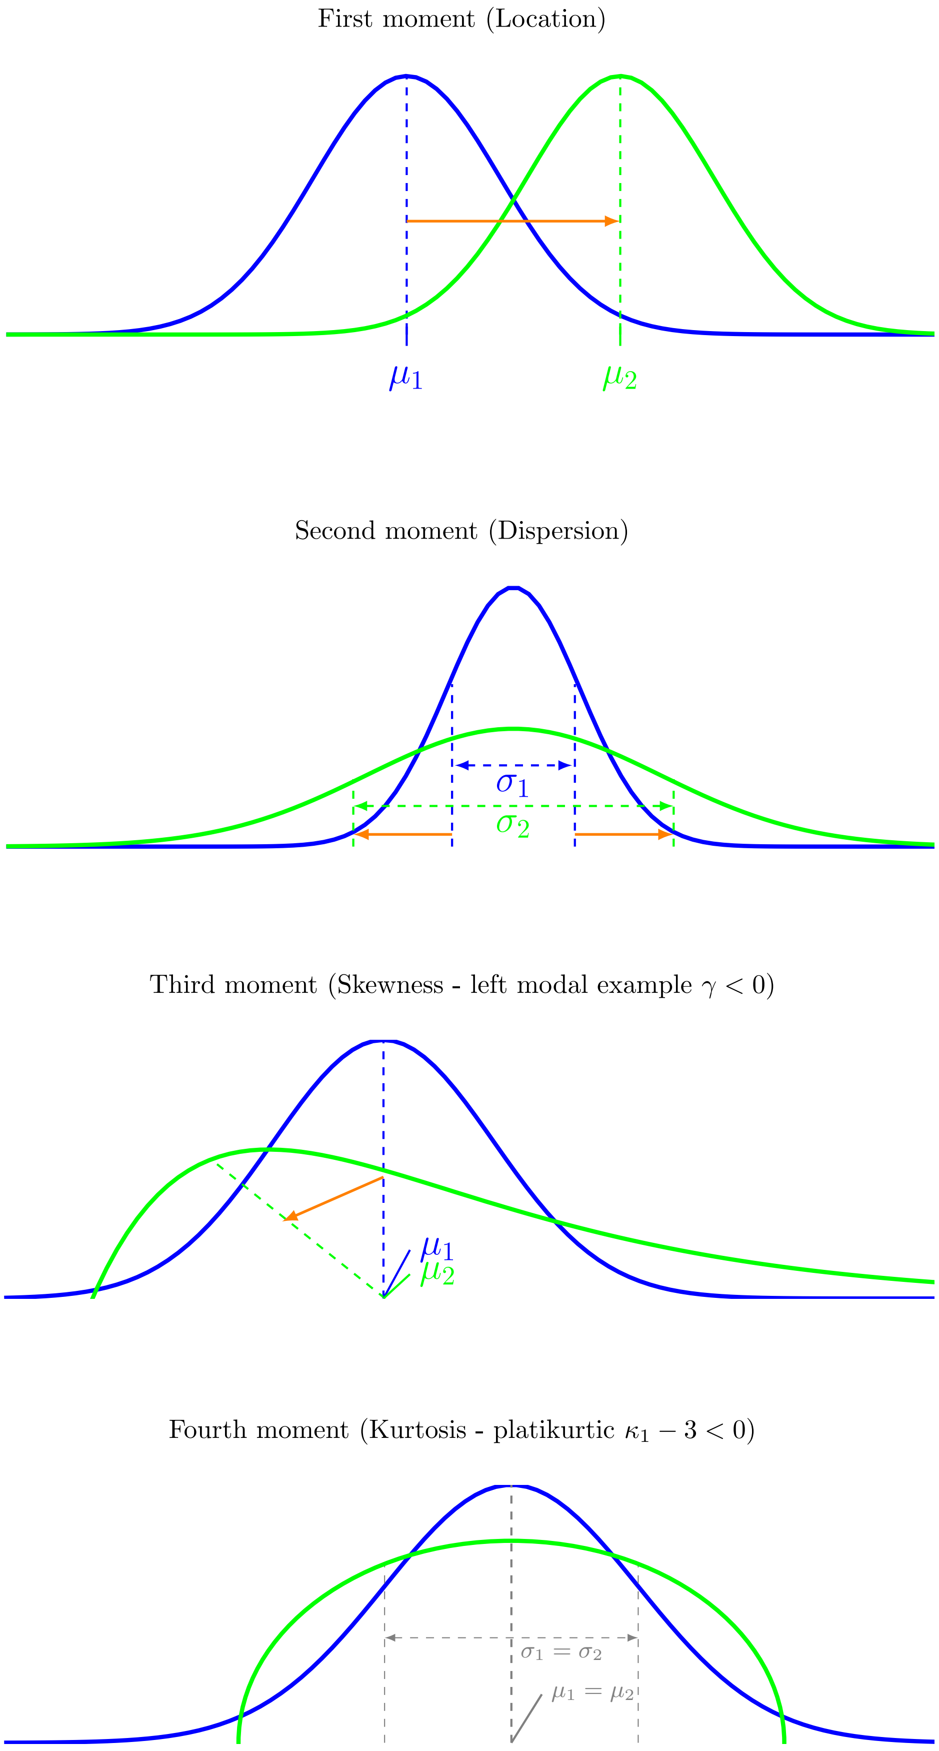
Rigorously kurtosis measure how far the underlying distribution is from being symmetric and bimodal (algebraically, a perfectly symmetric and bimodal distribution will have a kurtosis of 1, which is the smallest possible value the kurtosis can have). Most elementary texts describe kurtosis as a measure of the "peakedness" of a distribution. This term is misleading, and that a far better term for describing kurtosis is "bimodality," where the lower the kurtosis, the greater the bimodality.

Notice that the kurtosis may seems similar to the idea of measuring the dispersion (i.e. variance). However, one way to look at kurtosis is that it measures the width of a random distribution compared to that of a Normal distribution with the same mean and variance as the distribution in question. If the distribution is symmetric about the mean, a distribution with a positive kurtosis will have a sharper peak and much longer tails than does the Normal distribution. The opposite is the case for distributions with a negative kurtosis.

Here is an illustration:

---

[37] Rigorously a Normal distribution has a zero kurtosis. But the opposite is not true! Distributions that don't look Normal at all can have zero kurtosis!



First moment (Location)

Second moment (Dispersion)

Third moment (Skewness - left modal example $\gamma < 0$)

Fourth moment (Kurtosis - platikurtic $\kappa_1 - 3 < 0$)

Figure 5.116: **Kurtosis and Skewness range map of some distributions (author: Simon H. Hess)**

Remark

If one does image searches for the "kurtosis" on Google, quite a few images show the kurtosis as being only a Gaussian distributions with a greater or smaller second order moment (i.e. the Gaussian is just larger or smaller). Such images are misleading representations of kurtosis.

There have been a fairly large number of attempts to give measures corresponding to these notions, but these often-useful measures can be surprisingly counter-intuitive at times. For example, the moment-based skewness can be zero when the distribution is asymmetric (contradicting an assertion one can surprisingly often find when reading elementary texts which discuss skewness).

In facts moments of a continuous distribution, and functions of them like the kurtosis, tell you extremely little about the graph of its density function!!!! It should be abundantly clear that kurtosis and skewness is not an easily interpretable or intuitive measure of symmetry, unimodality, bimodality, convexity, or any other familiar geometric characterization of a curve. Functions of moments, therefore (and kurtosis as a special case) do not describe geometric properties of the graph of the probability density function. This intuitively makes sense: because a probability density function represents probability by means of area, we can almost freely shift probability density around from one location to another, radically changing the appearance of the probability density function, while fixing any finite number of pre-specified moments.

Here are the skewness used by `R` (implements γ_1, γ_2, γ_3), MATLAB® (implements γ_1, γ_2), Mathematica (implements γ_1), and MINITAB/IBM SPSS and Microsoft® Excel® (that implement γ_3):

$$\begin{aligned}
\gamma_1 &= \frac{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^3}{\left(\sqrt{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^2}\right)^3}=\frac{\mu_3}{\sigma^3}\\
\gamma_2 &= \gamma_1\frac{n}{(n-1)(n-2)}\\
\gamma_3 &= \gamma_1\left(\frac{n-1}{n}\right)^{3/2}\\
\gamma_{\text{Pearson mode}} &= \frac{\mu-M_0}{\sigma}\\
\gamma_{\text{Pearson median}} &= \frac{3(\mu-M_e)}{\sigma}\\
\gamma_{\text{Bowley}} &= B_1=\frac{Q_3+Q_1-2Q_2}{Q_3-Q_1}=\frac{\dfrac{Q_3+Q_1}{2}-Q_2}{\dfrac{Q_3-Q_1}{2}}\\
&\ldots
\end{aligned}\tag{5.7.348}$$

and the kurtosis used by `R` (implements κ_3, κ_4, κ_5), MATLAB® (implements κ_1, κ_2), Mathematica (implements κ_1), and MINITAB/IBM SPSS and Microsoft® Excel® (that implement

κ_3):

$$\begin{aligned}
\kappa_1 &= \frac{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^4}{\left(\sqrt{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^2}\right)^4} = \frac{\mu_4}{\sigma^4}\\
\kappa_2 &= \frac{(N-1)((N+1)\kappa_1-3(N+1))}{(N-2)(N-3)}+3\\
\kappa_3 &= \frac{N(N+1)}{(N-1)(N-2)(N-3)}\kappa_1-\frac{3(N-1)^2}{(N-2)(N-3)}\\
\kappa_4 &= \kappa_1-3\\
\kappa_5 &= (\kappa_4+3)\left(1-\frac{1}{N}\right)^2-3\\
&\ldots
\end{aligned} \tag{5.7.349}$$

From the relations above, only γ_1, γ_2, κ_1 and κ_3 are actually in the ISO 3534-1 standard.

Remark

It exist at least 11 methods to calculate the Skewness. See the study by Tabor, J. (12010 according to holocene calendar), *Investigating the Investigative Task: Testing for Skewness - An Investigation of Different Test Statistics and their Power to Detect Skewness*, Journal of Statistics Education, 18, 1-13. www.amstat.org/publications/jse/v18n2/tabor.pdf

Skewness γ_1 can be expressed in terms of the non-central moment $\mathrm{E}[X^3]$ by expanding its general definition (this form is very useful in practice to calculate the explicit skewness of a given distribution!):

$$\begin{aligned}
\gamma_1 &= \mathrm{E}\left[\left(\frac{X-\mu}{\sigma}\right)^3\right]\\
&= \frac{\mathrm{E}[X^3]-3\mu\mathrm{E}[X^2]+3\mu^2\mathrm{E}[X]-\mu^3}{\sigma^3}\\
&= \frac{\mathrm{E}[X^3]-3\mu(\mathrm{E}[X^2]-\mu\mathrm{E}[X])-\mu^3}{\sigma^3}\\
&= \frac{\mathrm{E}[X^3]-3\mu\sigma^2-\mu^3}{\sigma^3}
\end{aligned} \tag{5.7.350}$$

For a sample of n values, a natural method of moments estimator of the population skewness γ_1 is obviously as already defined earlier above:

$$\gamma_1 = \frac{\dfrac{1}{n}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^3}{\left(\sqrt{\dfrac{1}{n-1}\displaystyle\sum_{i=1}^{n}(x_i-\bar{x})^3}\right)^3} \tag{5.7.351}$$

Same for the Kurtosis:

$$\begin{aligned}\kappa_1 &= \mathrm{E}\left[\left(\frac{X-\mu}{\sigma}\right)^4\right]\\ &= \frac{\mathrm{E}[X^4]-4\mu\mathrm{E}[X^3]+6\mu^2\mathrm{E}[X^2]-4\mu^3\mathrm{E}[X]-\mu^4}{\sigma^4}\end{aligned} \tag{5.7.352}$$

Here is a figure giving an idea of the range values of skewness squared and kurtosis for some distributions:

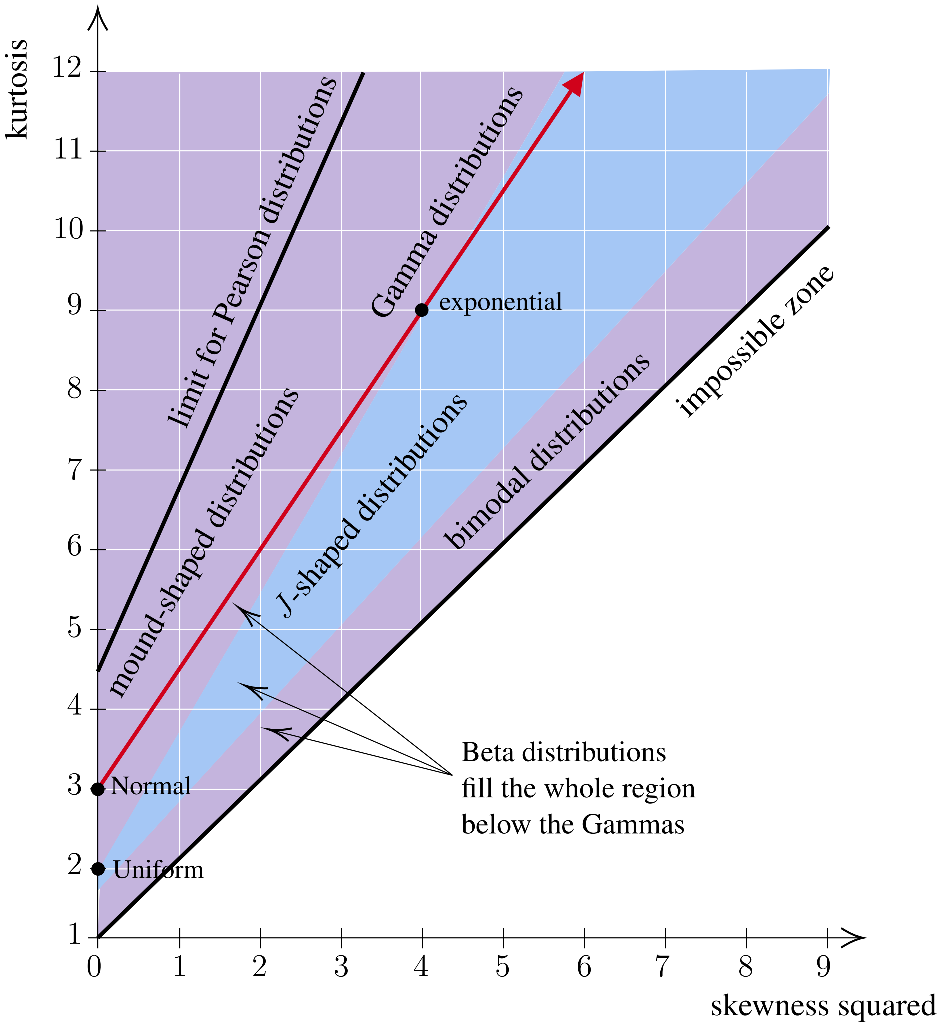


Figure 5.117: The Beta and Gamma families of distributions on the shape characterization plane

Later during the study of some important distributions, we will prove in details the values of the skewness and kurtosis for: the Uniform, Triangular, Normal, Student and the Beta distribution.

But before doing this let us prove an interesting theorem!

Theorem 5.46. Given a random variable X with symmetric probability density function $f(x)$, we have $\mathrm{E}(X)=a\mathrm{E}(X)=a$ where a is the point of symmetry assuming that $\mathrm{E}(X)$ exists.

Proof 5.46.1. First, it is obvious that symmetry about a means according to the assumptions of the theorem statement that:

$$f(a+z)=f(a-z) \tag{5.7.353}$$

for all z.

Suppose that the expectation $\mathrm{E}(X)$ exists. Then we know that:

$$\mathrm{E}(X)=\int\limits_{-\infty}^{+\infty} xf(x)\mathrm{d}x \tag{5.7.354}$$

Let us rewrite this as:

$$\mathrm{E}(X)=\int\limits_{-\infty}^{+\infty} (a+(x-a))f(x)\mathrm{d}x \tag{5.7.355}$$

which is equal to:

$$\int\limits_{-\infty}^{+\infty} af(x)\mathrm{d}x+\int\limits_{-\infty}^{+\infty} (x-a)f(x)\mathrm{d}x \tag{5.7.356}$$

The first integral is obviously equal to a as $f(x)$ is a density function.

In the second integral we make the change of variable $y=x-a$. Then this second integral becomes:

$$\int\limits_{-\infty}^{+\infty} yf(a+y)\mathrm{d}y \tag{5.7.357}$$

Break up at $y=0$. We get:

$$\int\limits_{-\infty}^{0} yf(a+y)\mathrm{d}y+\int\limits_{0}^{+\infty} yf(a+y)\mathrm{d}y \tag{5.7.358}$$

For the first integral, make the change of variable $z=-y$. We get:

$$\int\limits_{+\infty}^{0} (-1)(-z)f(a-z)\mathrm{d}z \tag{5.7.359}$$

Using $f(a-z)=f(a+z)$, and some minor fooling with minus signs, we end up with:

$$-\int\limits_{0}^{+\infty} zf(a+z)\mathrm{d}z \tag{5.7.360}$$

Therefore:

$$\int\limits_{-\infty}^{0} yf(a+y)\mathrm{d}y+\int\limits_{0}^{+\infty} yf(a+y)\mathrm{d}y \tag{5.7.361}$$

becomes:

$$-\int_{0}^{+\infty} zf(a+z)\mathrm{d}z+\int_{0}^{+\infty} yf(a+y)\mathrm{d}y \tag{5.7.362}$$

And this is equal to zero! Then we have:

$$\int_{-\infty}^{+\infty} af(x)\mathrm{d}x+\int_{-\infty}^{+\infty}(x-a)f(x)\mathrm{d}x=a+\left(-\int_{0}^{+\infty} zf(a+z)\mathrm{d}z+\int_{0}^{+\infty} yf(a+y)\mathrm{d}y\right)=a+0=a \tag{5.7.363}$$

■ Q.E.D.

Remark

The skewness and kurtosis are fundamental moments to develop the famous Jarque-Bera test of normality or the famous Cornish-Fisher Value at Risk (we will see all that later in this textbook).

5.7.4 Fundamental postulate of statistics

One of the ultimate goals of statistics is, starting from a sample, to find the analytical distribution function that gave birth to the sample. This goal will be presented in this textbook as a postulate (even if this assumption is quite difficult to apply in practice).

Postulate: For any empirical distribution function $\hat{F}_n(x)$ of the n-th measurement of the x random variable we can associate a theoretical distribution function $F(x)$ to which it converges when the sample size is large enough if:

$$X_n=\sup|\hat{F}_n(x)-F(x)| \tag{5.7.364}$$

is the random variable defined as the largest difference (in absolute value) between $\hat{F}_n(x)$ and $F(x)$ (observed for all values of x for a given sample), then X_n converges to 0 almost surely.

Remark

Mathematicians of Statistics prove this postulate rigorously as a theorem named the "fundamental theorem of statistics" or the "Glivenko-Cantelli theorem" regarding continuous functions. Personally, even if we offends the experts, we think that this proof is not one because it is very far away from the practical reality (yes this is our physicist side that emerges...) and this theoretical result leads many practitioners do their utmost (excluding data, transformations and other abominations) to find a known distribution law that they can adjust to their measured data.

5.7.5 Diversity Index

It happens in the field of biology or business that you it is asked to a statistician or analyst to measure the diversity of a number of predefined elements. For example, imagine a multinational with a range of well-defined products and some of the stores (customers) in the world can choose a subset of this range for their business sales. The request is then to make a ranking of stores that sell the widest range of branded products and that by taking also into account the quantity.

For example, we have a list of a total 4 products in our catalogue. By hazard, three of our customers sell our 4 products but we would like to know which customers sells the greatest diversity and this by taking into account the quantities.

We have the following sales data by product for the customer 1:

Customer 1	
Product 1	5
Product 2	5
Product 3	5
Product 4	5

For the customer 2:

Customer 2	
Product 1	1
Product 2	1
Product 3	1
Product 4	17

and for the customer 3:

Customer 3	
Product 1	2
Product 2	2
Product 3	2
Product 4	34

A measure of information (diversity of states) that is well suited to this purpose is the Shannon formula introduced in the section of Statistical Mechanics (page 3530) whose mean:

$$S(x)=\mathrm{E}(h(x))=-\lambda\sum_{i=1}^{n}p_i\log(p_i) \tag{5.7.365}$$

Arbitrarily, we will take $\lambda=1$ and the logarithm in base 10 (so, if we have 10 equiprobable variables, entropy is unitary for example...).

Therefore we have:

$$S(x)=-\sum_{i=1}^{n}p_i\log_{10}(p_i) \tag{5.7.366}$$

We will rewrite this more adequately for the application in business. Thus, if n is the number of products and p_i the proportion (or "relative frequency") of sales of product i from all sales N then:

$$p_i=\frac{f_i}{N} \tag{5.7.367}$$

Then we have:

$$\begin{aligned}S(x)&=-\sum_{i=1}^{n}\frac{f_i}{N}\log_{10}(\frac{f_i}{N})=-\frac{1}{N}\sum_{i=1}^{n}f_i\,[\log_{10}(f_i)-\log_{10}(N)]\\&=\frac{\displaystyle\sum_{i=1}^{n}f_i\,[\log_{10}(N)-\log_{10}(f_i)]}{N}=\frac{\log_{10}(N)\displaystyle\sum_{i=1}^{n}f_i-\sum_{i=1}^{n}f_i\log_{10}(f_i)}{N}\\&=\frac{N\log_{10}(N)-\displaystyle\sum_{i=1}^{n}f_i\log_{10}(f_i)}{N}\end{aligned} \tag{5.7.368}$$

This gives for the customer 1 (we stay in base 10 for the logarithm):

$$\begin{aligned}S_1&=\frac{N\log(N)-\displaystyle\sum_{i=1}^{n}f_i\log(f_i)}{N}\\&=\frac{20\log(20)-(5\log(5)+5\log(5)+5\log(5)+5\log(5))}{20}\\&=\frac{20\log(20)-20\log(5)}{20}=\log(20)-\log(5)=\log(4)=0.602\end{aligned} \tag{5.7.369}$$

which is the maximum possible value (each state is equally likely). And for customer 2 we have:

$$\begin{aligned}S_2&=\frac{N\log(N)-\displaystyle\sum_{i=1}^{n}f_i\log(f_i)}{N}\\&=\frac{20\log(20)-(1\log(1)+1\log(1)+1\log(1)+17\log(17))}{20}=0.255\end{aligned} \tag{5.7.370}$$

And finally for customer 3:

$$\begin{aligned}S_3&=\frac{N\log(N)-\displaystyle\sum_{i=1}^{n}f_i\log(f_i)}{N}\\&=\frac{40\log(40)-(2\log(2)+2\log(2)+2\log(2)+34\log(34))}{40}=0.255\end{aligned} \tag{5.7.371}$$

Thus, the customer that has the greatest diversity is the first one. We also see an interesting property of the Shannon formula with customer 2 and 3 and this is that the quantity does not affect diversity (since the only difference between the two customers is that the quantity is multiplied by a factor of 2 and not diversity)!

Notice that if we put all the products in only one customer (set), we get:

$$\begin{aligned}S_{\text{tot}} &= \frac{N\log(N)-\displaystyle\sum_{i=1}^{n}f_i\log(f_i)}{N} \\ &= \frac{80\log(80)-(8\log(8)+8\log(8)+8\log(8)+56\log(56))}{80}=0.408\end{aligned} \tag{5.7.372}$$

Therefore we guess that (without general proof):

$$\boxed{S_{\text{tot}}\leq\sum_i S_i} \tag{5.7.373}$$

Hence the fact that it is better to have various product in one place than in multiple place (result used for example in the field of document management where the purpose is to avoid to have the same type of documents saved in different share drive or libraries).

5.7.6 Distribution Functions (probabilities laws)

When we observe probabilistic phenomena, and we take note of the values taken by them and that we report them graphically, we can observe that the individual measurements follow a typical characteristic which is sometimes adjustable theoretically with a good level of quality.

In the field of probabilities and statistics, we name these characteristics "distribution functions" because they indicate the frequency with which the random variable appears for given values.

Remark

We sometimes simply use the term "function" or "law" to describe these characteristics.

These functions are in practice bounded by what we name the "range of the distribution" which is the difference between the maximum value (on the right) and the minimum value (on the left) of the observed values:

$$R = \max - \min \tag{5.7.374}$$

In theory they are not necessarily bounded and then we talk (see section Functional Analysis page 2207) about a "domain of definition" or more simply about the "support" of the function.

If the observed values are distributed in a certain way then there is a probability (or "cumulative probability" in the case of continuous distribution functions) to have a certain value of the distribution function.

In industrial practice (see section Industrial Engineering page 8684), the range of statistical values is important (as well as the standard deviation) because it gives an indication of the variation of a process (variability).

If L denote any possible univariate distribution function the range of the function is simply denoted by L if its domain of definition is $\mathbb{R}$ otherwise if it is bounded you will typically see something like $L_{]a,b]}$.

Definitions (#5.7.133):

D1. The mathematical relation that gives the probability of a given value of the distribution function a random variable is named the "density function" (or "probability density function"), "mass function" or "marginal function".

D2. The mathematical relation that gives the cumulative probability that a random variable to be lower than or equal to a certain value of the distribution function is referred to as the "repartition function" or "cumulative function" or "cumulative distribution function".

D3. Random variables are "independent and identically distributed (i.i.d.)" if they all follow the same distribution function, with the same parameters values and that they are independent.

Such functions are very numerous, we offer then here to the reader a detailed study of the most known only.

Before going any further it could be useful to know that if X is a continuous or discrete random variable, then are several tradition of notation in the literature to indicate that it follows a given probability distribution L. Here are the most common:

$$\begin{aligned} X &\sim L\\ X &\overset{\mathcal{L}}{=} L\\ X &\mapsto L\\ X &= L \end{aligned}\tag{5.7.375}$$

In this section and throughout the book in general, we will use the last notation!

Here is the list of the univariate and multivariate distribution functions that we will see here as well as distribution functions commonly used in the industry and located in other chapters/sections and those whose proof has yet still to be written:

- Discrete Uniform distribution $\mathcal{U}(a,b)$ (see below)
- Bernoulli distribution $\mathrm{B}(1,p)$ (see below)
- Geometric distribution $\mathcal{G}(N)$ (see below)
- Binomial distribution $\mathcal{B}(N,k)$ (see below)
- Binomial Negative distribution $\mathrm{NB}(N,k,p)$ (see below)
- Hypergeometric distribution $\mathcal{H}(n,p,m,k)$ (see below)
- Multinomial distribution $\mathcal{H}(\vec{k},\vec{p},m)$ (see below)
- Poisson distribution $\mathcal{P}(\mu,k)$ (see below)
- Gauss-Laplace/Normal distribution $\mathcal{N}(\mu,\sigma)$ (see below)
- General Folded Normal distribution (see below)
- Half-Normal distribution (see below)
- Log-Normal distribution $\mathcal{LN}(\mu,\sigma)$ (see below)
- Continuous Uniform distribution (see below)
- Triangular distribution (see below)
- Pareto distribution (see below)
- Exponential distribution (see below)
- Weibull distribution (see section Industrial Engineering page 8736)
- Generalized Exponential distribution (still must be written)
- Erlang/Erlang-B/Erlang-C distributions (see section Quantitative Management page 8147)
- Cauchy distribution (see below)
- Beta distribution (below and section Quantitative Management page 8076)
- Gamma distribution (see below)
- Chi-squared distribution (see below)
- Student distribution (see below)
- Fisher-Snedecor distribution (see below)
- Benford distribution (see below)
- Logistic distribution (see section Numerical Methods page 6453)
- Laplace distribution $\mathcal{L}(\mu,b)$ (see below)
- Square Gauss Distribution (see below)
- Exponentially modified Gaussian distribution (see below)
- Extreme value Distribution (still must be written)
- Vasicek distribution (already written but need to be reviewed)

All these distributions are mathematical evidence that randomness can produce precision!

By the way, for a more exhaustive list (almost a hundred!) and classification of distribution functions, the reader can see refer to the Data Science mind map at page 6770.

Remark

The reader will find the mathematical developments of the Weibull distribution function in the section on Industrial Engineering (page 8736), and the logistic distribution function in the section of Numerical Methods (page 6453).

> *All epistemologic value of the theory of probability is based on this: that large-scale random phenomena in their collective action create strict, non-random regularity.*

5.7.6.1 Discrete Uniform Distribution

If we accept that it is possible to associate a probability to an event, we can conceive of situations where we can assume a priori that all elementary events are equally likely (that is to say, they have the same probability to occur). We then use the ratio between the number of favourable cases and the number of possible cases to calculate the probability of all events in the Universe of events U. More generally, if U is a finite set of equally likely events and A is part of U, then we have using set theory notation (see section Set Theory page 388):

$$P(A)=\frac{\text{Card}(A)}{\text{Card}(U)}=\frac{\#A}{\#U} \tag{5.7.376}$$

More commonly, if e is an event that may have N equally likely possible outcomes. Then the probability of observing the outcome of this given event follows a "discrete uniform function" (or "discrete uniform law") given by the relation:

$$\boxed{P_e=\frac{1}{N}} \tag{5.7.377}$$

And obviously this is also equal to the modal (mode) value of the distribution.

Whose mean (or average) is given by:

$$\text{E}(X)=\sum_i p_i x_i=\sum_i P_e x_i=P_e\sum_i x_i=\frac{1}{N}\sum_i x_i \tag{5.7.378}$$

If we put ourselves in the particular case where $x_i=1$ with $i=1\ldots N$. We then have (see section Sequences and Series page 1666):

$$\text{E}(X)=\frac{1}{N}\sum_i x_i=\frac{1}{N}\sum_{i=1}^{N} i=\frac{1}{N}\frac{N(N+1)}{2}=\frac{N+1}{2} \tag{5.7.379}$$

Obviously the as this distribution is symmetric to the mean, the median is equal to mean.

If the random variable e take all values between $[a,b]$ (another special case) such the distribution will be now denoted by $\mathcal{U}(a,b)$ and the probability mass function of e is:

$$f_e(x)=\frac{1}{b-a+1}\qquad\text{where}\qquad x\in\{a,a+1,\ldots,b-1,b\}\tag{5.7.380}$$

as the number of integers between and including a and b is $n=b-a+1$. It is immediate that the cumulative distribution function is given by:

$$F_e(x)=\begin{cases}0\text{ if }x<a\\ \dfrac{\lfloor x\rfloor-a+1}{b-a+1}\text{ if }a\leq x\leq b\\ 1\text{ if }x>b\end{cases}\tag{5.7.381}$$

and it should be obvious that we have for the expected mean:

$$\begin{aligned}\mathrm{E}(X)&=\sum_{i=a}^{b}P_e i=P_e\sum_{i=a}^{b}i=\frac{1}{b-a+1}\sum_{i=a}^{b}i=\frac{1}{b-a+1}\left(\sum_{i=1}^{b}i-\sum_{i=1}^{a-1}i\right)\\&=\frac{1}{b-a+1}\left(\frac{b(b+1)}{2}+\frac{(a-1)((a-1)+1)}{2}\right)=\frac{1}{b-a+1}\frac{b(b+1)-a(a-1)}{2}\\&=\frac{1}{b-a+1}\frac{(b-a+1)(b+a)}{2}=\frac{a+b}{2}\end{aligned}\tag{5.7.382}$$

For the variance we have (always using the results of the section on Sequences and Series page 1667):

$$\begin{aligned}\mathrm{V}(X)&=\sum_{i=1}^{N}p_i(i-\mu)^2=\sum_{i=1}^{N}P_e(i-\mu)^2=\sum_{i=1}^{N}\frac{1}{N}(i-\mu)^2=\frac{1}{N}\sum_{i=1}^{N}(i-\mu)^2\\&=\frac{1}{N}\left(\sum_{i=1}^{N}i^2-2\mu\sum_{i=1}^{N}i+\sum_{i=1}^{N}\mu^2\right)=\frac{1}{N}\left(\sum_{i=1}^{N}i^2-2\mu\sum_{i=1}^{N}i+N\mu^2\right)\\&=\frac{1}{N}\sum_{i=1}^{N}i^2-\frac{2}{N}\mu\sum_{i=1}^{N}i+\mu^2=\frac{1}{N}\frac{N(N+1)(2N+1)}{6}-\frac{2}{N}\frac{N+1}{2}\sum_{i=1}^{N}i+\left(\frac{N+1}{2}\right)^2\\&=\frac{(N+1)(2N+1)}{6}-\frac{N+1}{N}\sum_{i=1}^{N}i+\frac{(N+1)^2}{4}\\&=\frac{(N+1)(2N+1)}{6}-\frac{N+1}{N}\frac{N(N+1)}{2}+\frac{(N+1)^2}{4}\\&=\frac{(N+1)(2N+1)}{6}-\frac{(N+1)^2}{2}+\frac{(N+1)^2}{4}=\frac{(N+1)(2N+1)}{6}-\frac{(N+1)^2}{4}\\&=\frac{2(N+1)(2N+1)-3(N+1)^2}{12}=\frac{2(2N^2+N+2N+1)-3N^2-6N-3}{12}\\&=\frac{4N^2+6N+2-3N^2-6N-3}{12}=\frac{N^2-1}{12}\end{aligned}\tag{5.7.383}$$

If the random variable e take all values between $[a,b]$ (another special case) such the distribution will be now denoted by $\mathcal{U}(a,b)$ then it should be obvious that we have for the variance:

$$\text{V}(X)=\frac{N^2-1}{12}=\frac{(b-a+1)^2+1}{12} \tag{5.7.384}$$

By symmetry of the distribution if all values of the domain of definition $[a,b]$ are taken by the random variable we have for the median:

$$M_e=\text{E}(X)=\frac{a+b}{2} \tag{5.7.385}$$

Here is a plot example of the mass distribution function and cumulative distribution function respectively for discrete uniform law of parameters $\{1,5,8,11,12\}$ (we see that each value is equally likely):

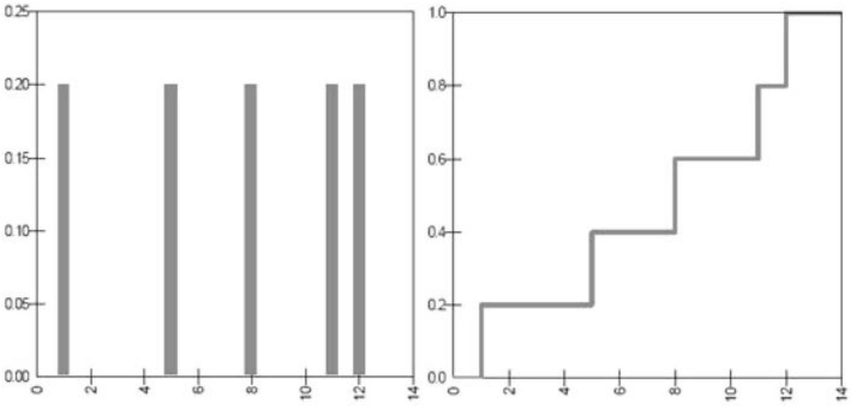

Figure 5.118: **Uniform law $\mathcal{U}$ (density and cumulative distribution function)**

As we can see in the above diagram the cumulative distribution function can be written:

$$F(x)=P(X\leq x)=\frac{\#(i:x_i\leq x)}{N} \tag{5.7.386}$$

Remark

For sure the discrete uniform distribution has no specific modal value M_0!

Let e be a random variable following a discrete uniform distribution $e\sim\mathcal{U}(a,b)$. Then, the quantile function of e is:

$$Q_e(p)=a(1-p)+(b+1)p-1 \quad \text{when } p\in\left\{\frac{1}{n},\frac{2}{n},\ldots,\frac{b-a}{n},1\right\} \tag{5.7.387}$$

with $n=b-a+1$. Remember that the quantile function $Q_X(p)$ is in general defined as the smallest x, such that $F_X(x)=p$:

$$Q_X(p)=\min\{x\in\mathbb{R}\mid F_X(x)=p\} \tag{5.7.388}$$

Because the cumulative distribution function only returns multiples of $1/n$ with $n = b - a + 1$, the quantile function is only defined for such values. First, we have $Q_X(p) = -\infty$, if $p = 0$. Second, since the cumulative probability increases step-wise by $1/n$ at each integer between and including a and b, the minimum x at which:

$$F_e(x) = \frac{c}{n} \quad \text{where} \quad c \in \{1, \ldots, n\} \tag{5.7.389}$$

is given by:

$$Q_e\left(\frac{c}{n}\right) = a + \frac{c}{n} \cdot n - 1 = a + c - 1 \tag{5.7.390}$$

Substituting $p = c/n$ and $n = b - a + 1$, we can finally show:

$$\begin{aligned} Q_e(p) &= a + p \cdot (b - a + 1) - 1 \\ &= a + pb - pa + p - 1 \\ &= a(1-p) + (b+1)p - 1 \end{aligned} \tag{5.7.391}$$

We will prove in the section of Statistical Mechanics (see page 3542) that the discrete uniform distribution maximizes (Shannon) entropy for a random variable with finite support.

5.7.6.2 Bernoulli Distribution

If we are dealing with a binary observation then the probability of an event is constant from one observation to the other if there is no memory effect (in other words: a sum of Bernoulli variables, two by two independent).

We name this kind of observations where the random variables takes the values 0 (false) or 1 (true), with probability $q = 1 - p$ respectively p, "Bernoulli trials" with "contrary events with contrary probabilities".

Thus, a random variable X follows a "Bernoulli function" $\text{B}(1, p)$ (or "Bernoulli law") if it can take only the values 0 or 1 , associated with probabilities p and q and so that $q + p = 1$ and:

$$\boxed{P(X = 0) = q \qquad P(X = 1) = p = 1 - q} \tag{5.7.392}$$

The classic example of such a process is the game of piece face or sampling with replacement or be considered as such (this last case is very important in industrial practice). There certainly is no need for the reader to formally verify that the cumulative probability is unitary...

Remark

The introduction above is perhaps not relevant for business, but we will see in the section of Quantitative Techniques (page 8141) that the Bernoulli function naturally appears at the beginning of our study of queuing theory.

Note that, by extension, if we consider N events where we get in a particular order k times one possible outcomes (success) and the other $N - k$ (fail) times, then the probability of such a series (k successes and $N - k$ failures ordered in any particular way) is given intuitively by (applying independent events rule):

$$P(N, k) = p^k (1-p)^{N-k} = p^k q^{N-k} \tag{5.7.393}$$

with $N \in \mathbb{N}^*$.

Here is an example plot of the cumulative distribution function for $q = 0.3$:

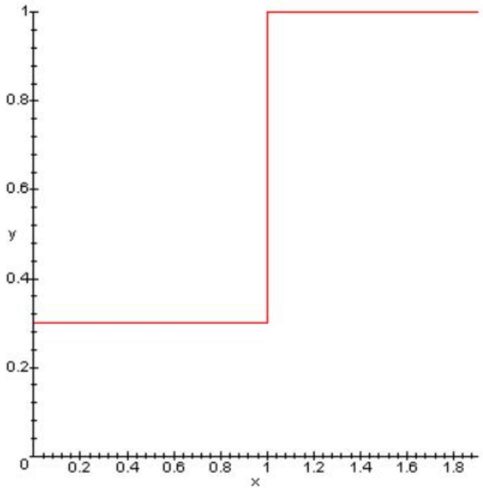

Figure 5.119: **Bernoulli law B (cumulative distribution function)**

The Bernoulli function has therefore for expected mean (average) choosing p as the probability of the event of interest:

$$\mu = \mathrm{E}(X) = \sum_i p_i x_i = p \cdot 1 + (1-p) \cdot 0 = p \tag{5.7.394}$$

and for variance (we use the Huygens theorem proved above):

$$\mathrm{V}(X) = \sigma^2 = \mathrm{E}(X^2) - \mathrm{E}(X)^2 = p - p^2 = p(1-p) = pq \tag{5.7.395}$$

The modal value M_0 of the Bernoulli law depends on the values of p or q. So we have (it could be obvious for the reader):

$$\begin{aligned} M_0 &= 0 \Leftrightarrow p < q \\ M_0 &= \{0,1\} \Leftrightarrow p = q \\ M_0 &= 1 \Leftrightarrow q > 0 \end{aligned} \tag{5.7.396}$$

Remark

For sure the Bernoulli distribution has no specific median value M_e!

5.7.6.3 Geometric Distribution

The geometric law $\mathcal{G}(N)$ or "Pascal's law" consist in a Bernoulli trial, where the probability of success is p and that of failure $q = 1 - p$ are constant, that we renew independently until the first success.

Remember that during our presentation of the Bernoulli law we have deduce an extension to N such that:

$$P(N,k) = p^k(1-p)^{N-k} = p^k q^{N-k} \tag{5.7.397}$$

Therefore the probability to get the first success $k = 1$ after N trials is:

$$\boxed{\mathcal{G}(N) = p(1-p)^{N-1} = pq^{N-1}} \tag{5.7.398}$$

with $N \in \mathbb{N}^*$.

As you can see, greater is N, smaller is the probability $\mathcal{G}(N)$. This can be seem non-logic but in fact it is! Indeed in the sentence «*the probability to get the first success after N trials*», you must not forget that it is written after and not during.

Therefore for sure... the probability to have $N - 1$ failures followed by 1 success will be always be smaller when N increase (have a look to the figure a little bit further below for $p = 0.5$, it may help to understand).

This law has for expected mean:

$$\mu = \mathrm{E}(X) = \sum_i p_i x_i = \sum_{N=1}^{+\infty} pq^{N-1}N = \sum_{N=1}^{+\infty} p(1-p)^{N-1}N = p\sum_{N=1}^{+\infty}(1-p)^{N-1}N \tag{5.7.399}$$

However, the last relation can also be written:

$$\sum_{N=1}^{+\infty} Nq^{N-1} = \frac{1}{(1-q)^2} \tag{5.7.400}$$

Indeed, we proved in the section of Sequences and Series (page 1679) during our study of geometric series that:

$$\sum_{k=0}^{n} q^k = \frac{1-q^{n+1}}{1-q} \tag{5.7.401}$$

Taking the limit $n \to +\infty$ when we get:

$$\sum_{k=0}^{+\infty} q^k = \frac{1}{1-q} \tag{5.7.402}$$

because $0 \leq q < 1$. Then we just derive both members of equality with respect to q and we get:

$$\sum_{k=1}^{+\infty} kq^{k-1} = \frac{1}{(1-q)^2} \tag{5.7.403}$$

This done let us continue...

We have then the average number of trials X it takes to get the first success (or in other words, the expected rank - number of expected trials - to see the first success):

$$\text{E}(X)=\sum_{N=0}^{+\infty}NP(X=N)=\sum_{N=0}^{+\infty}Npq^{N-1}=\frac{p}{(1-q)^2}=\frac{p}{p^2}=\frac{1}{p} \tag{5.7.404}$$

Now we calculate the variance and reminding once again (Huygens theorem):

$$\text{V}(X)=\text{E}(X^2)-\text{E}(X)^2 \tag{5.7.405}$$

So let's start by calculating $\text{E}(X^2)$:

$$\begin{aligned}\text{E}(X^2)&=\sum_{N=0}^{+\infty}N^2P(X=N)=p\sum_{N=0}^{+\infty}N^2q^{N-1}=p\sum_{N=0}^{+\infty}N(N-1+1)q^{N-1}\\&=p\sum_{N=1}^{+\infty}N(N-1)q^{N-1}+p\sum_{N=0}^{+\infty}Nq^{N-1}\end{aligned} \tag{5.7.406}$$

The last term of this expression is equivalent to the expected mean calculated previously. Thus:

$$p\sum_{N=0}^{+\infty}Nq^{N-1}=\frac{1}{p} \tag{5.7.407}$$

It remains to calculate:

$$p\sum_{N=1}^{+\infty}N(N-1)q^{N-1} \tag{5.7.408}$$

We have:

$$p\sum_{N=1}^{+\infty}N(N-1)q^{N-1}=pq\sum_{N=2}^{+\infty}N(N-1)q^{N-2} \tag{5.7.409}$$

But deriving the following equality:

$$\sum_{k=1}^{+\infty}kq^{k-1}=\frac{1}{(1-q)^2} \tag{5.7.410}$$

We get:

$$\sum_{k=1}^{+\infty}k(k-1)q^{k-2}=\frac{2}{(1-q)^3} \tag{5.7.411}$$

Therefore:

$$pq\sum_{N=2}^{+\infty}N(N-1)q^{N-2}=pq\frac{2}{(1-q)^3}=pq\frac{2}{p^3}=\frac{2q}{p^2} \tag{5.7.412}$$

Thus:

$$\mathrm{E}(X^2)=\frac{2q}{p^2}+\frac{1}{p^2} \tag{5.7.413}$$

Finally when it comes to ranking the expected variance of the first success (i.e.: the variance expected number before the first successful trials):

$$\mathrm{V}(X)=\sigma^2=\mathrm{E}(X^2)-\mathrm{E}(X)^2=\frac{2q}{p^2}+\frac{1}{p}-\frac{1}{p^2}=\frac{1-p}{p^2} \tag{5.7.414}$$

The modal value is easy to get because we need to find the value of N that maximize the definition of the geometric law:

$$pq^{N-1} \tag{5.7.415}$$

and we hope that it is immediate to the reader that this is satisfy when $N=1$ therefore:

$$M_0=pq^{1-1}=pq^0=p \tag{5.7.416}$$

Now let us determine the median M_e. For this, by definition we know we must have:

$$\sum_{N=1}^{M_e}pq^{N-1}=\sum_{N=M_e}^{+\infty}pq^{N-1}=0.5 \tag{5.7.417}$$

But we can rewrite:

$$\sum_{N=1}^{M_e}pq^{N-1}=\sum_{N=M_e}^{+\infty}pq^{N-1}=pq^{M_e-1}\sum_{N=0}^{+\infty}q^N=pq^{M_e-1}\frac{1}{1-q}=pq^{M_e-1}\frac{1}{p}=q^{M_e-1}=0.5 \tag{5.7.418}$$

Therefore (in base 10):

$$\log\left(q^{M_e-1}\right)=(M_e-1)\log(q)=\log(0.5) \tag{5.7.419}$$

Finally, based on our definition of the median, we get:

$$M_e=\frac{\log(0.5)}{\log(q)}+1 \tag{5.7.420}$$

Now we determine the cumulative function of the geometrical law. We start from:

$$\mathcal{G}(N)=pq^{N-1} \tag{5.7.421}$$

Then we have, by definition of the cumulative probability, that the experience is successful in the first N trials:

$$P(X\leq N)=1-\sum_{j=N+1}^{+\infty}pq^{j-1}=1-p\sum_{j=N+1}^{+\infty}q^{j-1} \tag{5.7.422}$$

with N being for sure an integer of values $0,1,2,\ldots$.

We write:

$$j-1=n+k \Rightarrow k=n-j+1 \tag{5.7.423}$$

We then have for the cumulated distribution function:

$$\begin{aligned}P(X \leq N) &= 1-p\sum_{k=0}^{+\infty} q^{N+k} = 1-p\sum_{k=0}^{+\infty} q^N q^k = 1-pq^N\sum_{k=0}^{+\infty} q^k = 1-pq^N\sum_{k=0}^{+\infty} q^k \\ &= 1-pq^N\frac{1}{1-q} = 1-(1-q)q^N\frac{1}{1-q} = 1-q^N\end{aligned} \tag{5.7.424}$$

✍**Example:**

You try late at night and in the dark, to open a lock with a bunch of five keys, without attention, because you are a little tired (or a little tipsy ...) you will try each key. Knowing that only one key will work, what is the probability of using the right key at the N-th test?

The solution is:

$$\mathcal{G}(N) = pq^{N-1} = \frac{1}{5}\left(\frac{4}{5}\right)^{N-1} \tag{5.7.425}$$

Plot of the mass function and cumulative distribution function for the Geometric law with parameter $p=0.5$:

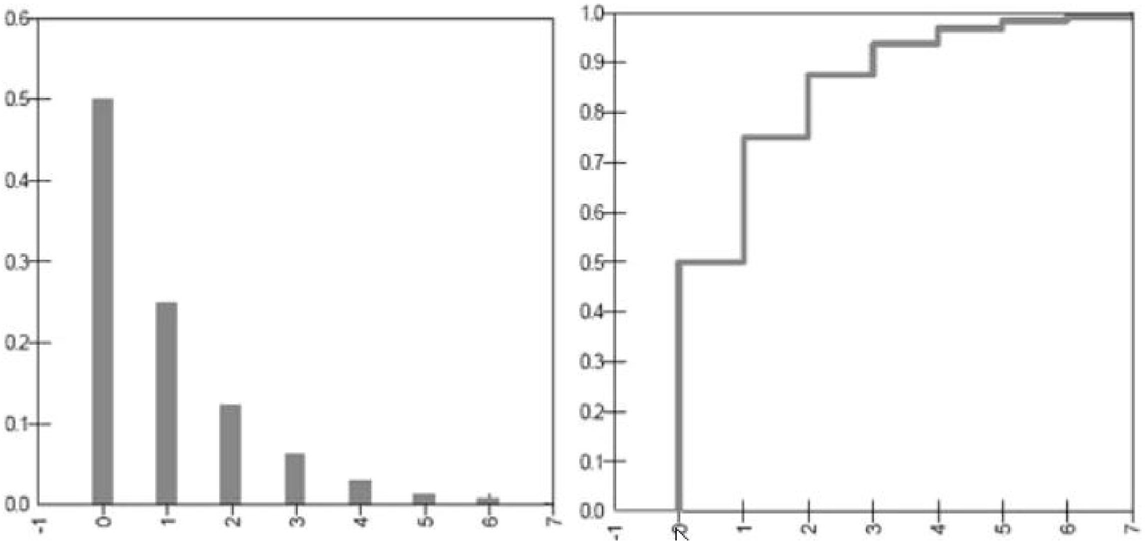

Figure 5.120: **Geometric law $\mathcal{G}$ (mass and cumulative distribution function)**

5.7.6.4 Binomial Distribution

We come back now to our Bernoulli experiment. More generally, any particular N-tuple consisting of k successes and of $N-k$ failures will have for probability (within a sampling with replacement or without replacement if the population is large ... in a first approximation):

$$P(N,k)=p^k(1-p)^{N-k}=p^kq^{N-k} \tag{5.7.426}$$

to be drawn (or appear) whatever the order of appearance of successes and failures (the reader will have perhaps notice that this is a generalization of the geometric distribution, just write $k=1$ to find the geometric distribution back).

But we know that the combinatorial determines the number of N-tuples of this type (the number of ways to order the appearance of failures and successes). The number of possible arrangements is, as we proved it (see section Probabilities page 528), given by the binomial coefficient (we recall that the notation in this textbook does not comply with ISO standard 31-11):

$$C_k^N=\frac{N!}{k!(N-k)!} \tag{5.7.427}$$

So as the probability of obtaining a given series of k successes and $N-k$ failures is always the same (regardless of the order) then we have just to multiply the probability of a particular series by the binomial coefficient (this is equivalent to a sum) such that:

$$P(N,k)=C_k^NP=\frac{N!}{k!(N-k)!}p^k(1-p)^{N-k}=\frac{N!}{k!(N-k)!}p^kq^{N-k} \tag{5.7.428}$$

to get the total probability to obtain any of these possible series (since each is possible).

Remark

This is equivalent to the study of a sampling with simple replacement (see section Probabilities page 528) with constraint on the order or to the study of a series of successes and failures. We will use this relation in the context of the queuing theory or reliability (see section Industrial Engineering page 8673). Note that in the case of large populations, even if the sampling is not with replacement it can be considered as with...

Written in another way this gives the "binomial function" (or "binomial law"), also known as the following distribution function:

$$\boxed{\mathcal{B}(N,k)=C_k^Np^k(1-p)^{N-k}=C_k^Np^kq^{N-k}=\binom{N}{k}p^kq^{N-k}} \tag{5.7.429}$$

and sometimes also denoted by $\beta(n,p)$ with a lowercase n or uppercase N (it does not really matter...) and can be calculated in the English version of Microsoft® Excel® 11.8346 using the `BINOMDIST( )` function.

We sometimes say that the binomial law is not exhaustive as the size of the initial population is not apparent in the expression of the law.

The binomial distribution appears across a wide span of scientific and engineering fields wherever researchers model processes made of repeated, independent trials with two possible outcomes. It is central in biology and medicine for analyzing genetic inheritance patterns, mutation rates, and clinical trial success counts; in physics and chemistry for modeling particle detection events, reaction successes, or defect formation; in computer science and information theory for packet-loss modeling, randomized algorithms, and error-correcting codes; in electrical and mechanical engineering for reliability analysis, component failure probabilities, and quality-control sampling; in environmental science for species-occurrence surveys and detection probabilities; and in social sciences for survey response modeling and behavioral event counts, and it also plays a clear role in quantitative finance, where it underpins discrete-time models of asset prices, option valuation, and risk assessment. Across these domains, the binomial distribution provides a mathematically clean way to quantify how often a “success” should occur when conditions are stable and repeatable.

Remark

The Binomial distribution is named "Symmetric Binomial Distribution" when $p = 0.5$.

✍**Examples:**

E1. We want to test the alternator of a generator. The probability of failure at solicitation of this material is estimated to be 1 failure per $1,000$ starts.

We decided to test 100 starts. The probability of observing one failure in this test is:

$$\begin{aligned}\mathcal{B}(N=100,k=1)=C_k^N p^k(1-p)^{N-k}&=\frac{N!}{k!(N-k)!}p^k(1-p)^{N-k}\\&=\frac{100!}{1!(100-1)!}\left(\frac{1}{1000}\right)^1\left(1-\frac{1}{1000}\right)^{99}\cong 9\%\end{aligned}\tag{5.7.430}$$

E2. Maybe you remember the prosecutor’s fallacy we have introduced at page 477. Let us come back on the example related to the crime-scene DNA sample. Now that we have introduced the binomial distribution, we can calculate the probability of getting at least one match among the record:

$$\mathcal{B}(N=20000,k=1)=C_k^N p^k(1-p)^{N-k}=\frac{N!}{k!(N-k)!}p^k(1-p)^{N-k}\cong 27.07\%\tag{5.7.431}$$

So, this evidence alone is an uncompelling data hacking result. If the culprit was in the database then he and one or more other men would probably be matched; in either case, it would be a fallacy to ignore the number of records searched when weighing the evidence. "Cold hits" like this on DNA databanks are now understood to require careful presentation as trial evidence.

We obviously have for the cumulative distribution function (very useful in practice for suppliers batch control or reliability as we will see in the section of Industrial Engineering page 8904!):

$$\sum_{k=0}^{N}C_k^N p^k(1-p)^{N-k}=1\tag{5.7.432}$$

Indeed, we have proved in the section Calculus (page 1364) the "binomial theorem":

$$(x+y)^n=\sum_{k=0}^{n} C_k^n x^k y^{n-k}=1 \tag{5.7.433}$$

Therefore:

$$\sum_{k=0}^{N} C_k^N p^k (1-p)^{N-k}=(p+(1-p))^N=1^N=1 \tag{5.7.434}$$

Instead of calculating such cumulated probability rather than hand it is better to use Microsoft® Excel® 11.8346 (or any other widely known software) with the function `CRITBINOM()` to not bother to calculate these type of values.

The expected mean (average) of $\mathcal{B}(N,k)$ is given by:

$$\mathrm{E}(X)=\sum_{k=0}^{N} p_i k=\sum_{k=0}^{N} P(X=k)k=\sum_{k=0}^{N} C_k^N p^k (1-p)^{N-k}k=\sum_{k=1}^{N} C_k^N p^k (1-p)^{N-k}k \tag{5.7.435}$$

But having:

$$C_k^N=\frac{N}{k}C_{k-1}^{N-1}\Leftrightarrow kC_k^N=NC_{k-1}^{N-1} \tag{5.7.436}$$

We finally get:

$$\begin{aligned}\mathrm{E}(X)&=\sum_{k=1}^{N} C_k^N p^k (1-p)^{N-k}=N\sum_{k=1}^{N} C_{k-1}^{N-1} p^k (1-p)^{N-k}\\&=Np\sum_{k=1}^{N} C_{k-1}^{N-1} p^{k-1} (1-p)^{(N-1)-(k-1)}=Np\sum_{k=0}^{N-1} C_k^{N-1} p^k (1-p)^{(N-1)-k}\\&=Np(p+(1-p))^{N-1}=Np\end{aligned} \tag{5.7.437}$$

that gives the average number of times that we will get the desired outcome of probability p after N trials.

The mean of the binomial distribution is sometimes noted in the specialized literature with the following notation if r is the potential number of possible expected outcomes in a population of size n:

$$\mathrm{E}(X)=Np=N\frac{r}{n} \tag{5.7.438}$$

Before calculating the variance, we need to introduce the following equality:

$$\sum_{s=0}^{N-1} s\frac{(N-1)!}{s!(N-1-s)!}p^s q^{N-1-s}=(N-1)p \tag{5.7.439}$$

Indeed, let us proof this relation using the previous developments:

$$\begin{aligned}&\sum_{s=0}^{N-1} s\frac{(N-1)!}{s!(N-1-s)!}p^sq^{N-1-s}=\sum_{s=0}^{N-1} s\frac{(N-1)!}{s(s-1)!(N-1-s)!}p^sq^{N-1-s}\\&=\sum_{s=1}^{N-1}\frac{(N-1)!}{(s-1)!(N-1-s)!}p^sq^{N-1-s}=(N-1)\sum_{s=1}^{N-1}\frac{(N-2)!}{(s-1)!(N-1-s)!}p^sq^{N-1-s}\\&=(N-1)\sum_{j=0}^{N-2}\frac{(N-2)!}{j!(N-2-j)!}p^{j+1}q^{N-2-j}=(N-1)p\sum_{j=0}^{N-2}C_j^{N-2}p^jq^{N-2-j}\\&=(N-1)p\sum_{j=0}^{N-2}C_j^{N-2}p^jq^{N-2-j}\end{aligned} \tag{5.7.440}$$

We recognize in the last equality the cumulative distribution function that is equal to 1. Therefore:

$$(N-1)p\sum_{j=0}^{N-2}C_j^{N-2}p^jq^{N-2-j}=(N-1)p\cdot 1=(N-1)p \tag{5.7.441}$$

We start now the (long) calculation of the variance of the binomial distribution by using the previous results:

$$\begin{aligned}
\text{V}(k) &= \sum_{k=0}^{N} p_i(k-\mu)^2 = \sum_{k=0}^{N} \frac{N!}{k!(N-k)!}p^kq^{N-k}(k-Np)^2 = \sum_{k=0}^{N} \frac{N!}{k!(N-k)!}p^kq^{N-k}(k-\mu)^2 \\
&= \sum_{k=0}^{N} k^2\frac{N!}{k!(N-k)!}p^kq^{N-k} + \sum_{k=0}^{N} \mu^2\frac{N!}{k!(N-k)!}p^kq^{N-k} - \sum_{k=0}^{N} 2k\mu\frac{N!}{k!(N-k)!}p^kq^{N-k} \\
&= \sum_{k=0}^{N} k^2\frac{N!}{k!(N-k)!}p^kq^{N-k} + \mu^2\sum_{k=0}^{N} \frac{N!}{k!(N-k)!}p^kq^{N-k} - 2\mu\sum_{k=0}^{N} k\frac{N!}{k!(N-k)!}p^kq^{N-k} \\
&= \sum_{k=0}^{N} k^2\frac{N!}{k!(N-k)!}p^kq^{N-k} + \mu^2\underbrace{\sum_{k=0}^{N} C_k^N p^kq^{N-k}}_{=1} -2\mu\underbrace{\sum_{k=0}^{N} k\frac{N!}{k!(N-k)!}p^kq^{N-k}}_{=\mu=Np} \\
&= \sum_{k=0}^{N} k^2\frac{N!}{k!(N-k)!}p^kq^{N-k} + \mu^2 - 2\mu^2 = \sum_{k=0}^{N} k^2\frac{N!}{k!(N-k)!}p^kq^{N-k} - \mu^2 \\
&\underset{s=k-1}{=} -\mu^2 + N\sum_{s=0}^{N-1}(s+1)\frac{(N-1)!}{s!(N-1-s)!}p^sq^{N-(s+1)} \\
&= -\mu^2 + Np\sum_{s=0}^{N-1}(s+1)\frac{(N-1)!}{s!(N-1-s)!}p^sq^{N-s-1} \\
&= -\mu^2 + Np\sum_{s=0}^{N-1} s\frac{(N-1)!}{s!(N-1-s)!}p^sq^{(N-1)-s} + Np\sum_{s=0}^{N-1} s\frac{(N-1)!}{s!((N-1-s)!}p^sq^{(N-1)-s)} \\
&= -\mu^2 + Np\sum_{s=0}^{N-1} sC_s^{N-1}p^sq^{(N-1)-s} + Np\sum_{s=0}^{N-1} sC_s^{N-1}p^sq^{(N-1)-s)} \\
&= -\mu^2 + Np(N-1)p + Np\sum_{s=0}^{N-1} sC_s^{N-1}p^sq^{(N-1)-s)} \\
&= -\mu^2 + Np^2(N-1) + Np\cdot 1 = -\mu^2 + Np^2(N-1) + Np \\
&= -\mu^2 + N^2p^2 - Np^2 + Np = -\mu^2 + \mu^2 - Np^2 + Np = Np(1-p) \\
&= Npq
\end{aligned} \tag{5.7.442}$$

Finally:

$$\text{V}(k) = \sigma^2 = Np(1-p) = Npq \tag{5.7.443}$$

The standard deviation of the binomial distribution is sometimes noted in the specialized literature in the following way if r is the potential number of expected outcomes in a population of size n and s the not expected one:

$$\sigma = \sqrt{Npq} = \sqrt{N\frac{r}{n}\frac{s}{n}} = \frac{1}{n}\sqrt{Nrs} \tag{5.7.444}$$

Here is a plot example of the binomial $\mathcal{B}(10, 0.5)$ distribution and cumulative distribution function:

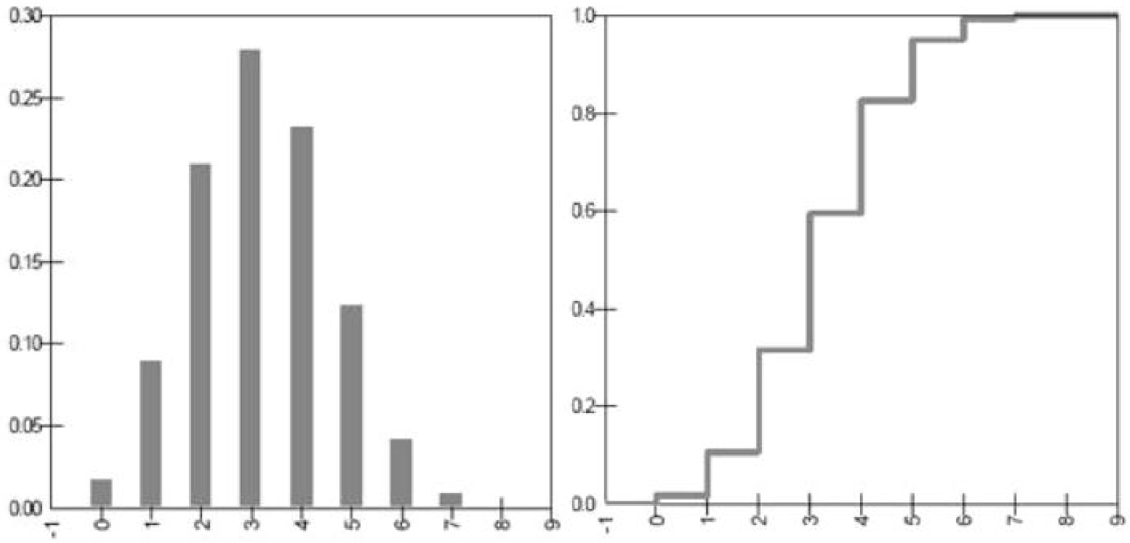

Figure 5.121: Binomial law $\mathcal{B}$ (mass and cumulative distribution function)

It could be useful to note that some employees in companies (especially physicians in the field of survival analysis - clinical studies - as we will see later!) normalize the calculation of the mean and standard deviation to the unit of N. Then we have:

$$\begin{gathered}\mathrm{E}\left(\frac{k}{N}\right)=\frac{Np}{N}=p\\ \mathrm{V}\left(\frac{k}{N}\right)=\frac{1}{N^2}\mathrm{V}(X)=\frac{1}{N^2}Npq=\frac{1}{N}p(1-p)\Leftrightarrow\sigma_{k/N}=\sqrt{\frac{p(1-p)}{N}}\end{gathered}\tag{5.7.445}$$

✍**Example:**

In a sample of 100 workers, 25% are late at least once a week. The mean number and variance of late people is then:

$$\begin{gathered}\mathrm{E}(k)=Np=100\cdot 0.25=25\\ \sigma_k=\sqrt{Np(1-p)}=\sqrt{100\cdot 0.25(1-0.25)}\cong 4.33\end{gathered}\tag{5.7.446}$$

Normalized to the unit of N this give us:

$$\begin{gathered}\mathrm{E}\left(\frac{k}{N}\right)=p=0.25\\ \sigma_{k/N}=\sqrt{\frac{p(1-p)}{N}}=0.0433\end{gathered}\tag{5.7.447}$$

Let us now calculate the mode. Because the function is discrete we can not use derivative. Then we will use a hint. We compute the ratio:

$$\frac{\mathcal{B}(N,k)}{\mathcal{B}(N,k+1)}\tag{5.7.448}$$

and we check that this ratio is > 1 for every $k < k^*$ and ≤ 1 for every $k \geq k^*$, for some integer k^* that is the k value corresponding to the modal value.

Let $a_k = P(X = k)$. We have:

$$a_k = C_k^N p^k q^{N-k} \qquad a_{k+1} = C_{k+1}^N p^{k+1} q^{N-k-1} \tag{5.7.449}$$

We calculate the ratio $\dfrac{a_{k+1}}{a_k}$. Note that:

$$\frac{a_{k+1}}{a_k} = \frac{C_{k+1}^N p^{k+1} q^{N-k-1}}{C_k^N p^k q^{N-k}} = \frac{\dfrac{N!}{(k+1)!(N-(k+1))!}}{\dfrac{N!}{k!(N-k)!}} \frac{p^{k+1} q^{N-k-1}}{p^k q^{N-k}} = \frac{n-k}{k+1}\frac{p}{q} = \frac{n-k}{k+1}\frac{p}{1-p} \tag{5.7.450}$$

What is important now is to analyse:

$$\frac{n-k}{k+1}\frac{p}{1-p} = \frac{np-kp}{k-kp+1-p} \tag{5.7.451}$$

depending on the value of k. First we can see that this ratio is equal to 1 and therefore we have two modes if:

$$\frac{np-kp}{k-kp+1-p} = 1 \Leftrightarrow np-kp = k-kp+1-p \tag{5.7.452}$$

That is to say if $k = np+p-1 = p(n+1)-1$. This can be seen as the limit point of interest. But don't forget we are looking for the k such that the ratio is less than 1. So we try two values:

$$\begin{aligned} k &= [p(n+1)-1]+1 \\ k &= [p(n+1)-1]-1 \end{aligned} \tag{5.7.453}$$

Injecting this in our ratio we see that:

$$k = [p(n+1)-1]+1 = k^* = M_0 \tag{5.7.454}$$

Is the value we were looking for! Finally there are two possible values for the modes. A unique modal value and a double modal value.

As we know, the median value is the value of X such that we have:

$$\sum_{k=0}^{X} C_k^N p^k (1-p)^{N-k} = 0.5 \tag{5.7.455}$$

But we did not yet found an easy proof to determine M_e in the general case for the Binomial law.

To conclude on the binomial law, we will develop now a result that we will need to build the McNemar paired test for a square contingency table (and as it is squared it is also dichotomous) that we will study further below (page 1264).

We need for this test to calculate the covariance of two-paired binomial random variables (this is why the covariance is non-zero):

$$\text{cov}(n_i,n_j)=\text{E}(n_in_j)-\text{E}(n_i)(n_j) \tag{5.7.456}$$

As they are paired, this means that:

$$\begin{gathered}n_i+n_j=n\\ p_i=1-p_j\\ 1-p_i=p_j\end{gathered} \tag{5.7.457}$$

And therefore:

$$\text{cov}(n_i,n_j)=\text{E}(n_in_j)-\text{E}(n_i)(n_j)=\text{E}(n_in_j)-(np_i)(np_j)=\text{E}(n_in_j)-n^2p_j(1-p_j) \tag{5.7.458}$$

Now comes the difficulty that is to calculate $\text{E}(n_in_j)$. To calculate this term it does not exist to our knowledge other methods than looking for the law of the pair (sometimes we can get around such approach). In this case it is a multinomial distribution (more precisely: trinomial) that it is customary to write in the following way by construction:

$$\mathcal{M}(n_i,n_j,p_i,p_j,1-p_i-p_j)=\frac{n!}{n_i!n_j!(n-n_i-n_j)!}p_i^{n_i}p_j^{n_j}(1-p_i-p_j)^{n-n_i-n_j} \tag{5.7.459}$$

that we will write now temporarily as following to condense the expression:

$$\mathcal{M}(n,k,l,p,q,r)=\frac{n!}{k!l!(n-k-l)!}p^kq^lr^{n-k-l}=\frac{n!}{k!l!(n-k-l)!}p^kq^l(1-p-q)^{n-k-l} \tag{5.7.460}$$

So we have a trinomial law as we are looking for the number of times we have the event k, the event l and neither one nor the other (so the rest of the time).

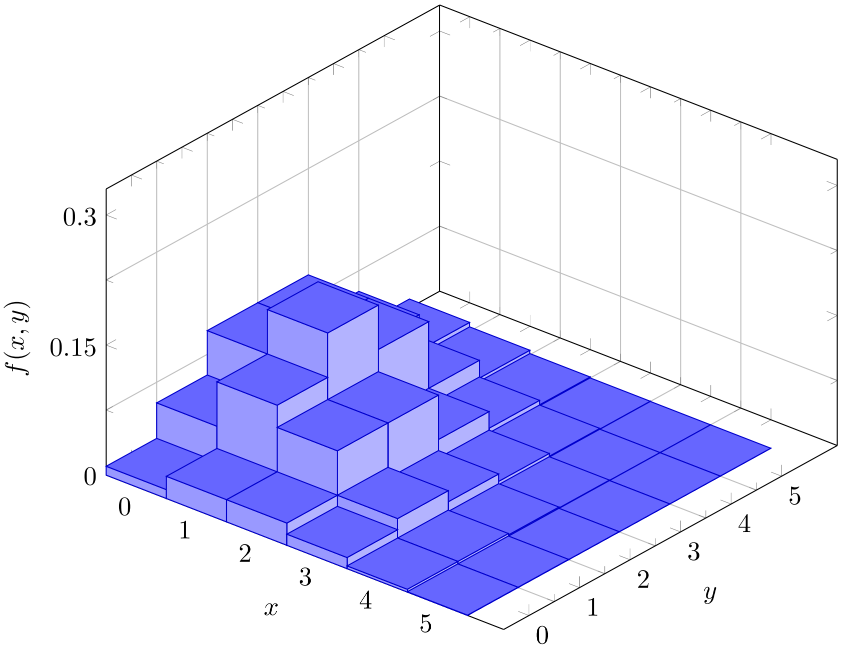

Figure 5.122: Trinomoial distribution with $p=1/5,q=2/5$ and $n=5$

We then get:

$$\begin{aligned}\mathrm{E}(kl)&=\sum_{k,l}klP(kl)=\sum_{k,l}\frac{n!}{k!l!(n-k-l)!}p^kq^lr^{n-k-l}\\&=\underbrace{0}_{k=0,l\neq 0}+\underbrace{0}_{l=0,k\neq 0}+\underbrace{0}_{k=0,l=0}+\sum_{k\geq 1,l\geq 1}kl\frac{n!}{k!l!(n-k-l)!}p^kq^lr^{n-k-l}\end{aligned}\tag{5.7.461}$$

If $k\geq 1$ and $l\geq 1$, we obtain:

$$\begin{aligned}kl\frac{n!}{k!l!(n-k-l)!}&=\frac{n!}{k(k-1)!l(l-1)!(n-k-l)!}=\frac{n(n-1)(n-2)!}{(k-1)!(l-1)!(n-k-l)!}\\&=n(n-1)\frac{(n-2)!}{(k-1)!(l-1)!(n-k-l)!}\end{aligned}\tag{5.7.462}$$

Now we use this relation in the joint mean:

$$\begin{aligned}\mathrm{E}(kl)&=\sum_{k\geq 1,l\geq 1}kl\frac{n!}{k!l!(n-k-l)!}p^kq^lr^{n-k-l}\\&=n(n-1)\sum_{1\leq k\leq n,1\leq l\leq n}kl\frac{(n-2)!}{k(k-1)!l(l-1)!(n-k-l)!}p^kq^lr^{n-k-l}\\&=n(n-1)pq\sum_{1\leq k\leq n,1\leq l\leq n}\frac{(n-2)!}{(k-1)!(l-1)!(n-k-l)!}p^{k-1}q^{l-1}r^{n-k-l}\end{aligned}\tag{5.7.463}$$

Consider now the special case where n is equal 2. We then have:

$$\begin{aligned}&\sum_{1\leq k\leq n,1\leq l\leq n}\frac{(n-2)!}{(k-1)!(l-1)!(n-k-l)!}p^{k-1}q^{l-1}r^{n-k-l}\\&=\sum_{1\leq k\leq 2,1\leq l\leq 2}\frac{0!}{(k-1)!(l-1)!(2-k-l)!}p^{k-1}q^{l-1}r^{2-k-l}\\&=\frac{0!}{(1-1)!(1-1)!(2-1-1)!}p^{1-1}q^{1-1}r^{2-1-1}=1\end{aligned}\tag{5.7.464}$$

where the sum is reduced to only one term because if we take for example $k=2,l=1$ we get a negative factorial at the denominator.

For n equal 3, the result will be also 1, and so on (we will assume to simplify... that some numerical examples will suffice to convince the reader of the generality of this property because it is very boring to write with LaTeX).

Then we have:

$$\mathrm{E}(kl)=n(n-1)pq\underbrace{\sum_{1\leq k\leq n,1\leq l\leq n}\frac{(n-2)!}{(k-1)!(l-1)!(n-k-l)!}p^{k-1}q^{l-1}r^{n-k-l}}_{=1}=n(n-1)pq\tag{5.7.465}$$

So in the end:

$$\text{cov}(n_i,n_j)=\text{E}(n_in_j)-n^2p_j(1-p_j)=n(n-1)p_ip_j-n^2p_ip_j=-np_ip_j \tag{5.7.466}$$

It does make sense for the covariance to be negative, since the more there are in category 1, the fewer are available for category 2. And this is the major result we will need for the study of the McNemar test.

Let X and Y be independent binomial random variables with parameters (n,p) and (m,p), respectively. Let $Z=X+Y$. Then the distribution of Z is given by:

$$\begin{aligned}
P(Z=k)&=\sum_{i=0}^{k}P(X=i)P(Y=k-i)\\
&=\sum_{i=0}^{k}\binom{n}{i}p^i(1-p)^{n-i}\binom{m}{k-i}p^{k-i}(1-p)^{m-(k-i)}\\
&=\sum_{i=0}^{k}\binom{n}{i}p^k(1-p)^{n-i}\binom{m}{k-i}(1-p)^{m-k+i}\\
&=\sum_{i=0}^{k}\binom{n}{i}p^k(1-p)^{n+m-k}\binom{m}{k-i}\\
&=p^k(1-p)^{n+m-k}\sum_{i=0}^{k}\binom{n}{i}\binom{m}{k-i}=p^k(1-p)^{n+m-k}\binom{n+m}{k}
\end{aligned} \tag{5.7.467}$$

Hence the binomial distribution is indeed stable by addition:

$$\mathcal{B}(n,p)+\mathcal{B}(m,p)=\mathcal{B}(n+m,p) \tag{5.7.468}$$

Doing the same development with different probabilities and without forgetting that $p_i+p_j=1$ then we have:

$$\mathcal{B}(n,p_i)+\mathcal{B}(m,p_j)=\mathcal{B}(n+m,p_i+p_J) \tag{5.7.469}$$

5.7.6.5 Negative Binomial Distribution

The negative binomial distribution is applied in the same situation as for binomial distribution, but it gives the probability to have E failures before the R-th success when the probability of success is p (or, at contrary, the probability to have R success before E-th failure when the failure probability is p).

We will introduce this important distribution with an example. Consider this for this purpose the following probabilities:

$$P(\text{success})=0.2=p \qquad P(\text{failure})=0.8=1-p=q \tag{5.7.470}$$

Imagine that we have done 10 trials and we wanted to stop at the third success and that the 10th trial is the third successful one! We will write this:

$$[1\ 2\ 3\ 4\ 5\ 6\ 7\ 8\ 9]\ 10 \tag{5.7.471}$$

Now we highlight what we will consider as the successes (R) and failures (E):

$$\begin{matrix}[1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9] & 10\\ [\texttt{E} & \texttt{E} & \texttt{R} & \texttt{E} & \texttt{E} & \texttt{E} & \texttt{R} & \texttt{E} & \texttt{E}] & \texttt{R}\end{matrix} \qquad (5.7.472)$$

We have also 7 failures and 3 successes. In an experiment where the draws are independent (or can be considered as independent...), the probability that we get this particular result is:

$$(0.8)^7(0.2)^3 \qquad (5.7.473)$$

But the order of successes and failures in the bracketed part is irrelevant. So as we have 2 success among the 9 trial in brackets it follows that the probability of obtaining the same result regardless of the order is then using combinatorics:

$$C_2^9(0.8)^7(0.2)^3=\binom{9}{2}(0.8)^7(0.2)^3\cong 0.0603 \qquad (5.7.474)$$

Which corresponds to the probability of having 7 failures before the 3rd success (or otherwise seen: 3 successes after 10 trials). This can be written with Microsoft® Excel® 14.0.6123 or later ($7+3=10$ trials, 7 failures including 3 successes):

```
=NEGBINOMDIST(7,3,0.2,0)=0.0604
```

We now generalize the prior-previous notation by writing the number of failures k, N the total number of trials and p the probability of success:

$$\text{NB}(N,k,p)=C_{N-k-1}^{N-1}q^kp^{N-k}=\binom{N-k-1}{N-1}q^kp^{N-k} \qquad (5.7.475)$$

However, there are several possible notations because the previous relation is not very intuitive to practice as may have perhaps noticed the reader. Thus, if we denote k as the number of successes and not the number of failures, then we have (the most common writing way from my point of view among a lot of others notations) the following probability of having $N-k$ success before having a number k of failures with a probability p (or of failures before having k successes ... it's symmetrical!):

$$\text{NB}(N,k,p)=C_{N-1}^{k-1}q^{N-k}p^k=\binom{N-1}{k-1}p^kq^{N-k} \qquad (5.7.476)$$

therefore the comparison with the formulation of the binomial distribution proved above is then perhaps more obvious!

However, it is more common to write the previous relation by removing N because for the moment the notation is still perhaps not very clear. For this, we note R the number of successes, E the number of failures, p the probability of success and then comes the probability of having R success after E failures (this is perhaps much more clear...):

$$\text{NB}(R,E,p)=C_{E+R-1}^{E-1}q^{(E+R)-E}p^E=\binom{E+R-1}{E-1}p^Eq^R \qquad (5.7.477)$$

We sometimes find this last relation with another relation using explicitly the binomial coefficient:

$$\begin{aligned}\text{NB}(R,E,p)&=\binom{E+R-1}{E-1}q^Rp^E=\frac{(E+R-1)!}{(E-1)!R!}q^Rp^E=\frac{(E+R-1)!}{R!(E-1)!}q^Rp^E\\&=\binom{E+R-1}{R}q^Rp^E\end{aligned} \tag{5.7.478}$$

The cumulative probability that we have at least R successes before the E-th failure is obviously given by:

$$\sum_{R=0}^{N}\binom{E+R-1}{E-1}q^Rp^E \tag{5.7.479}$$

Remark

The name of this law comes from the fact that some statisticians use a definition of the binomial coefficient with a negative value for the expression of the function. Since this is a rather a rare notation, we do not want lose time to prove the origin of the name. You should also know that this law is also known as the "Pascal's law" (as well as the geometric distribution ...) in honour of Blaise Pascal and also as "Polya's law" in honour of George Pólya.

✍**Examples:**

E1. A long-term quality control has enabled us to compute the estimator of the proportion p of nonconforming pieces as equal to 2% at the output of a production line. We would like to know the cumulative probability to have 200 pieces before the 3rd defective piece appears. With Microsoft® Excel® 14.0.6123 or later it comes using the negative binomial distribution:

`=NEGBINOM.DIST(200,3,0.02,1)=77.35%`

E2. To compare with the binomial distribution, we can ask ourselves what is the cumulative probability of drawing 198 non-defective parts from 201 using Microsoft® Excel® 14.0.6123 or later:

`=BINOM.DIST(198,201,0.98,1)=76.77%`

Therefore we see that the difference is small. In fact the difference between the two laws is in practice so small that we then use almost always the binomial law (but you should still be careful with this choice!).

As usual, we will now determine the variance and mean of this law. Let's start with the mean of having R successes when the E-th failure appears knowing that the probability of a failure is p. For this we will use a very simple and ingenious trick (all art was thinking about it...). If we return to our initial example:

$$\begin{matrix}[1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9] & 10\\ [\texttt{R} & \texttt{R} & \texttt{E} & \texttt{R} & \texttt{R} & \texttt{R} & \texttt{E} & \texttt{R} & \texttt{R}] & \texttt{E}\end{matrix} \tag{5.7.480}$$

and we rewrite this example as follows:

$$\begin{matrix}[1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10] \\ [\underbrace{\texttt{R} \;\; \texttt{R} \;\; \texttt{E}}_{=X_1} & \underbrace{\texttt{R} \;\; \texttt{R} \;\; \texttt{R} \;\; \texttt{E}}_{=X_2} & \underbrace{\texttt{R} \;\; \texttt{R} \;\; \texttt{E}}_{=X_3}]\end{matrix} \quad (5.7.481)$$

We then notice that the third success R of the first notation can be decomposed into the sum of three geometric random variables such that:

$$R = X_1 + X_2 + \ldots + X_n \quad (5.7.482)$$

With in the case of this particular example $n = 3$ corresponding in fact to $E = 3$. So quite generally the sum of n random geometric variables always gives a negative binomial distribution if the probability p is equal for each geometric variable!!! Anyway... as we have proved the expression of the mean and variance of the Geometric law as (thus giving us the mean rank of the first failure):

$$\mathrm{E}(X) = \frac{1}{p} \qquad \mathrm{V}(X) = \frac{1-p}{p^2} = \frac{q}{p^2} \quad (5.7.483)$$

since the random variables are independent and of same parameters then it comes for the negative binomial the mean of the rank of E-th failure using the property of the mean:

$$\mathrm{E}(X) = \mathrm{E}(X_1 + X_2 + \ldots + X_n) = \mathrm{E}(X_1) + \mathrm{E}(X_2) + \ldots \mathrm{E}(X_n) = n\mathrm{E}(X) = n\frac{1}{p} = E\frac{1}{p} \quad (5.7.484)$$

And therefore for the variance of the negative binomial distribution:

$$\mathrm{V}(X) = \mathrm{V}(X_1 + X_2 + \ldots + X_n) = \mathrm{V}(X_1) + \mathrm{V}(X_2) + \ldots \mathrm{V}(X_n) = n\mathrm{V}(X) = n\frac{1-p}{p^2} = E\frac{q}{p^2} \quad (5.7.485)$$

So the mean and variance of the rank (corresponding to the number of trials N or from another point of view: the mean number of successes by the simple subtraction $X - E$) to have the E-th failure is then to summarize:

$$\begin{aligned}\mathrm{E}(X) &= \frac{E}{p} \\ \mathrm{V}(X) &= E\frac{1-p}{p^2}\end{aligned} \quad (5.7.486)$$

Thus, putting $E = 1$, we fall back on the mean and variance of the geometric distribution!

Now, let Y be the random variable representing the number of trials before the R-th success. We then have the following expressions for the variance and the mean that are very common in the literature (these expressions of mean and variance corresponds to what we can find for the negative binomial law in Wikipedia for example):

$$\begin{aligned}\mathrm{E}(Y) &= \mathrm{E}(X-1) = \mathrm{E}(X) - \mathrm{E}(1) = \mathrm{E}(X) - 1 = \frac{E}{p} - 1 = \frac{E-p}{p} = \frac{\mathrm{E}(1-p)}{p} \\ \mathrm{V}(Y) &= \mathrm{V}(X-1) = \mathrm{V}(X) + \mathrm{V}(1) = \mathrm{V}(X) = \frac{\mathrm{E}(1-p)}{p^2}\end{aligned} \quad (5.7.487)$$

✍**Example:**

What is the expected number (mean) of trials we can expect before we fall on the third non-conforming part, knowing that the probability of a non-conforming part is 2%?

$$\text{E}(X)=\dfrac{E}{p}=\dfrac{3}{2\%}=150 \tag{5.7.488}$$

and for the standard deviation:

$$\sigma=\sqrt{E\dfrac{q}{p^2}}=\sqrt{3\dfrac{(1-2\%)}{(2\%)^2}}=85.732 \tag{5.7.489}$$

Like always the reader will find below a plot example of the distribution and cumulative distribution function for the negative binomial law of parameters $\text{NB}(N,k,p)=P(N,3,0.6)$ based on the example of the begging, but where the only difference is the probability of success where we he have taken 60% instead of 20%.

Thus, there is 21.6% of probability of having the third success after the third successive trial (i.e. 0 trials more than the number of successes), 25.92% of probability of having the third success after the fourth successive trial (i.e. one trial more than the number of successes), 20.7% of probability of having the third success after the fifth successive trial (i.e. two trial more than the number of successes) and so on...:

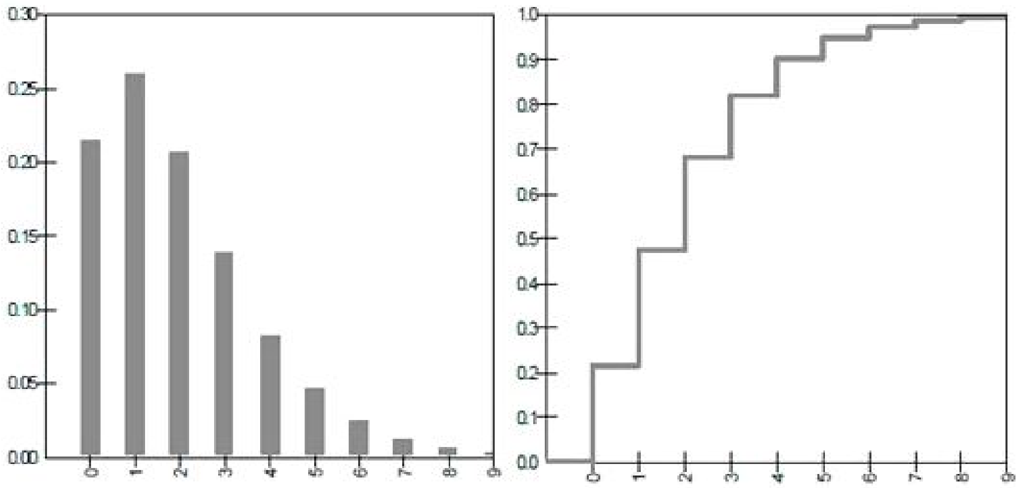

Figure 5.123: **Negative Binomial law `NB` (mass and cumulative distribution function)**

The above distributions are truncated to 9 (corresponding to 12 trials) but they theoretically continue indefinitely. What particularly distinguishes the binomial and geometric distributions from the negative binomial are the tails of the distribution.

The binomial negative distribution has an important place in a special regression technique that we will see in the section of Theoretical Computing at page 6316.

5.7.6.6 Hypergeometric Distribution

We consider to approach this function a simple example (but not very interesting in practice) that is this of an urn containing n balls where m are black and the other m' white (for several important examples used in the industry refer to the sections of Industrial Engineering page 8677). We take successively, and without replacement in the urn, p balls. The question is to find the probability that among the p balls, there is k that are black (in this statement the order of the drawing does not interest us).

We often talk about "exhaustive sampling" with the hypergeometric distribution because at the opposite of to the binomial distribution, the size of the lot which is the basis for the sampling will appear in the law.

> **Remark**
>
> This is also equivalent to a non-ordered sampling without replacement/repetition (see section Probabilities page 528) with constraint on the occurrences sometimes named "simultaneous sampling". We will often use the hypergeometric distribution in the field of quality and reliability where the black balls are associated to items with defects and the white one to items without defects.

The p balls can be chosen among n balls in C_p^n ways (thus representing the number of possible different outcomes) with as reminder (see section Probabilities page 528):

$$C_p^n = \binom{n}{p} = \frac{A_n^p}{p!} = \frac{n!}{p!(n-p)!} \tag{5.7.490}$$

The k black balls can be chosen among the m black in C_k^m ways. The $p-k$ white balls can be chosen in C_{p-k}^{n-m} ways. There is therefore $C_k^m C_{p-k}^{n-m}$ ways to have k black balls and $p-k$ white balls.

The searched probability is therefore given by (we will see an alternative notation in the section of Industrial Engineering page 8677):

$$\boxed{\mathcal{H}(n,p,m,k) = \frac{C_k^m C_{p-k}^{n-m}}{C_p^n} = \frac{\dfrac{m!}{k!(m-k)!}\dfrac{(n-m)!}{(p-k)!((n-m)-(p-k))!}}{\dfrac{n!}{p!(n-p)!}}} \tag{5.7.491}$$

and is said to follow a "Hypergeometric distribution" (or "Hypergeometric law") and can be obtained fortunately directly in Microsoft® Excel® 14.0.7153 with the function `HYPGEOM.DIST()`.

✍**Examples:**

E1. We want to develop a small computer program of $10,000$ lines of code (n). The return on experience shows that the probability of failure is one bug per $1,000$ lines of code (or 0.1% of $10,000$ lines) that corresponds to the value m.

We test about 50% of the functionality of the software randomly before sending it to the customer (corresponding to the equivalent of $5,000$ lines that is p). The probability of observing 5 bugs (k) is then given with Microsoft® Excel® 14.0.715:

`HYPGEOMDIST(k,p,m,n)=HYPGEOMDIST(5,5000,1%*10000,10000)=24.62%`

E2. In a small single production of a batch of $1,000$ pieces we know that 30% on average are bad because of the complexity of the pieces and by return on experience from a previous similar manufacturing. We know that a customer will randomly draw 20 pieces to decide whether to accept or reject the lot. He will not reject the lot if he finds zero defective pieces on the 20. What is the probability of having exactly 0 defective?

`=HYPGEOMDIST(0,20,300,1000)=0.073%`

and as we require a null draw drawing result, the calculation of the hypergeometric distribution simplifies manually to:

$$\frac{700}{1000}\frac{699}{999}\frac{698}{998}\frac{697}{997}\ldots\frac{681}{981}=0.073\% \tag{5.7.492}$$

It is not forbidden to make direct calculation of the mean and variance of the hypergeometric distribution, but the reader will without much trouble guess that this calculation will be ... relatively indigestible. Then we can use an indirect method that is much more interesting!

First, the reader will perhaps, even certainly, have noticed that experienced of the hypergeometric distribution is a series of Bernoulli trials (without replacement of course!).

So we will cheat by using initially the property of linearity of the mean. We define for this purpose a new variable corresponding implicitly in fact to the experience of the hypergeometric distribution (a sequence of k Bernoulli trials!):

$$X=\sum_{i=1}^{k}X_i \tag{5.7.493}$$

where X_i is the success of obtaining at the i-th drawing a black ball (either 0 or 1). But, we know that for all i the random variable X_i follows a Bernoulli function for which we have proved in our study of the Bernoulli distribution that $\text{E}(X_i)=p$.

Therefore, by the property of linearity of the mean we have (caution! here p is not the number of balls, but the probability associated with an expected event!):

$$\text{E}(X)=\text{E}\left(\sum_{i=1}^{k}X_i\right)=kp \tag{5.7.494}$$

In the Bernoulli trial, p is the probability of obtaining the desired item or event (for reminder...). In the hypergeometric distribution what interests us is the probability of a black ball (which are in quantity m, therefore with m' white balls) compared to the total amount of n balls. And the ratio obviously gives us this probability. Thus, we have:

$$\mu=\text{E}(X)=kp=k\frac{m}{m+m'}=k\frac{m}{n} \tag{5.7.495}$$

where k is the number of trials (do not confuse with the notation of the initial statement where it was by the variable p!). The mean gives then the average number of black balls in a drawing of k balls among n, where m are known as being black. The reader will have noticed that the mean of the hypergeometric distribution is the same as the binomial distribution!

To determine the variance, we use the variance of the Bernoulli distribution and the following relation proved during the introduction of the mean and covariance at the beginning of this chapter:

$$\text{V}(X+Y)=\text{V}(X)+\text{V}(Y)+2\text{cov}(X,Y)+\text{V}(X)+\text{V}(Y)+2(\text{E}(XY)-\text{E}(X)\text{E}(Y)) \tag{5.7.496}$$

Recalling that we have $X=\sum_{i=1}^{k} X_i$, we get:

$$\text{V}(X)=\text{V}\left(\sum_{i=1}^{k} X_i\right)=\sum_{i=1}^{k}\text{V}(X_i)+2\sum_{i=1\leq 1<j\leq n}^{k}(\text{E}(X_iX_j)-\text{E}(X_i)\text{E}(X_j)) \tag{5.7.497}$$

However, for the Bernoulli law, we have:

$$\text{V}(X)=pq=\frac{m}{m+m'}\frac{m'}{m+m'}=\frac{mm'}{(m+m')^2}=\frac{mm'}{n^2} \tag{5.7.498}$$

Then we first already get:

$$\text{V}\left(\sum_{i=1}^{k} X_i\right)=k\frac{mm'}{(m+m')^2}=k\frac{mm'}{n^2} \tag{5.7.499}$$

Afterwards, we have easily:

$$\text{E}(X_i)\text{E}(X_j)=\frac{m}{m'+m}\frac{m}{m'+m}=\left(\frac{m}{m'+m}\right)^2 \tag{5.7.500}$$

The calculation of $\text{E}(X_iX_j)$ requires a good understanding of probabilities (this will be a good refresh!).

The mean $\text{E}(X_iX_j)$ is given (implicitly), as we know, by the weighted sum of the probabilities that two events occur at the same time. However, our events are binary: either it is a black ball (1) or it is a white ball (0). So all terms of the sum without two consecutive black balls consecutively will be null!

The problem is then to calculate the probability of having two consecutive black balls and it is thus written:

$$\begin{aligned}P(X_iX_j=1)&=P((X_i=1)\cap(X_j=1))=P(X_i=1)P_{X_i=1}P(X_j=1)\\&=\frac{m}{m'+m}\frac{m-1}{(m'+m)-1}\end{aligned} \tag{5.7.501}$$

So we finally have:

$$\text{E}(X_iX_j)=\frac{m}{m'+m}\frac{m-1}{(m'+m)-1} \tag{5.7.502}$$

Therefore:

$$\begin{aligned}\text{cov}(X_i,X_j)&=\text{E}(X_iX_j)-\text{E}(X_i)(X_j)=\frac{m}{m'+m}\frac{m-1}{(m'+m)-1}-\left(\frac{m}{m'+m}\right)^2\\&=\frac{-mm'}{(m'+m)^2(m'+m-1)}\end{aligned}\tag{5.7.503}$$

Finally (using the result of Gauss series seen in the section of Sequences and Series page 1666):

$$\begin{aligned}\text{V}(X)&=\sum_{i=1}^{k}\text{V}(X_i)+2\sum_{i=1\leq 1<j\leq n}^{k}(\text{E}(X_iX_j)-\text{E}(X_i)\text{E}(X_j))\\&=k\frac{mm'}{(m'+m)^2}+2\frac{-mm'}{(m'+m)^2(m'+m-1)}\sum_{i=1\leq 1<j\leq n}^{k}1\\&=k\frac{mm'}{(m'+m)^2}+2\frac{-mm'}{(m'+m)^2(m'+m-1)}\frac{(k-1)k}{2}\\&=\frac{kmm'(m'+m-1)-mm'k(k-1)}{(m'+m)^2(m'+m-1)}=\frac{kmm'(m'+m-1-k+1)}{(m'+m)^2(m'+m-1)}\\&=\frac{kmm'(m'+m-k)}{(m'+m)^2(m'+m-1)}=k\frac{m}{m'+m}\frac{m'}{m'+m}\frac{m'+m-k}{m'+m-1}\\&=kpq\frac{m'+m-k}{m'+m-1}=kpq\frac{n-k}{n-1}\end{aligned}\tag{5.7.504}$$

where we have used the fact that:

$$\sum_{i<j}\text{cov}(X_i,X_j)\tag{5.7.505}$$

is composed of:

$$C_2^k=\binom{k}{2}=\frac{k(k-1)}{2}\tag{5.7.506}$$

terms that correspond to the number of ways there are to choose a pair (i,j) with $i<j$.

Because:

$$\text{V}(X)=kpq\frac{n-k}{n-1}=k\frac{m}{n}\frac{n-m}{n}\frac{n-k}{n-1}\tag{5.7.507}$$

We can write:

$$\sigma=\sqrt{kpq}\sqrt{\frac{n-k}{n-1}}=\sqrt{k\frac{m}{n}\frac{n-m}{n}}\sqrt{\frac{n-k}{n-1}}\tag{5.7.508}$$

In the specialized literature, we often find the variance written in the following way by noting the expected event r and the non-expected event s:

$$\text{V}(X)=kpq\frac{n-k}{n-1}=k\frac{r}{n}\frac{s}{n}\frac{n-k}{n-1}=\frac{krs(n-k)}{n^2(n-1)}=\frac{klrs}{n^2(n-1)}\tag{5.7.509}$$

so with $l=n-k$. This last notation will be very useful further below during our study of the Mantel-Haenszel test (page 1283). Furthermore, we see that in:

$$\sigma=\sqrt{kpq}\sqrt{\frac{n-k}{n-1}} \tag{5.7.510}$$

there is the standard deviation as the binomial distribution, at the difference of a factor that is noted:

$$\text{fpc}=\sqrt{\frac{n-k}{n-1}} \tag{5.7.511}$$

that we found often in statistics and is named "finite population correction factor".

Here is an example plot example of the distribution function and cumulative distribution for the Hypergeometric function of parameters $(n,p,m,k)=(10,6,5,k)$:

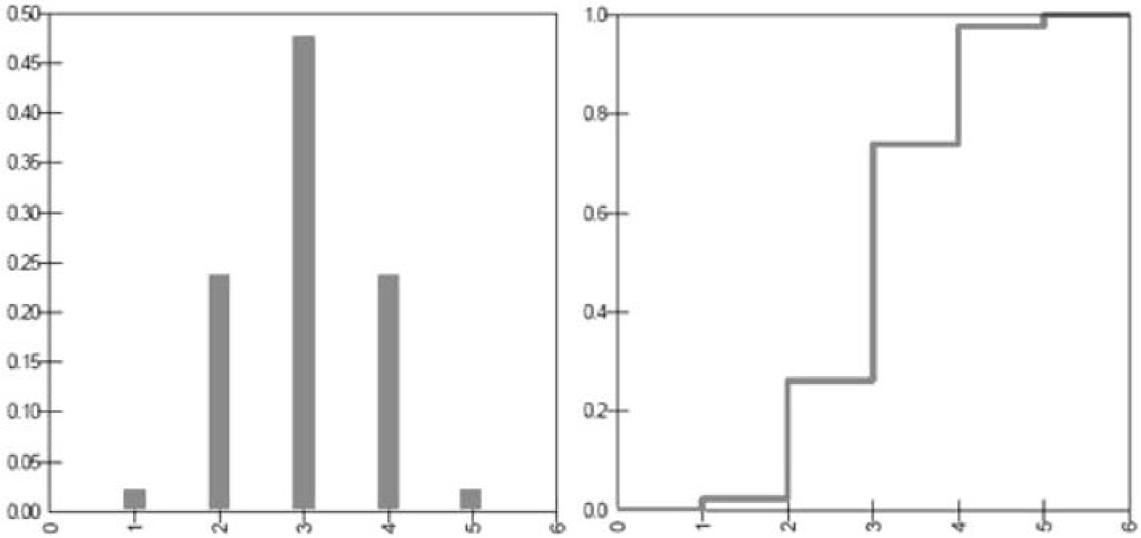

Figure 5.124: **Hypergeometric law $\mathcal{H}$ (mass and cumulative distribution function)**

We will prove now that the Hypergeometric distribution tends to a binomial distribution since this property is used many times in different sections of this textbook (especially the section of Industrial Engineering page 8677).

To do this, we decompose:

$$\mathcal{H}(n,p,m,k)=\frac{C_k^m C_{p-k}^{n-m}}{C_p^n} \tag{5.7.512}$$

We then get:

$$\begin{aligned}\frac{C_k^m C_{p-k}^{n-m}}{C_p^n}&=\frac{\dfrac{m!}{k!(m-k)!}\dfrac{(n-m)!}{(p-k)!((n-m)-(p-k))!}}{\dfrac{n!}{p!(n-p)!}}\\&=\frac{m!}{k!(m-k)!}\frac{(n-m)!}{(p-k)!((n-m)-(p-k))!}\frac{p!(n-p)!}{n!}\\&=\frac{p!}{k!(p-k)!}\frac{m}{(m-k)!}\frac{(n-m)!}{(p-k)!((n-m)-(p-k))!}\frac{(n-p)!}{n!}\\&=C_p^k\frac{m}{(m-k)!}\frac{(n-m)!}{(p-k)!((n-m)-(p-k))!}\frac{(n-p)!}{n!}\end{aligned}\tag{5.7.513}$$

For the second term:

$$\frac{m}{(m-k)!}=\frac{1\cdot 2\cdot 3\cdot\ldots\cdot m}{1\cdot 2\cdot 3\cdot\ldots\cdot(m-k)}=m(m-1)\ldots(m-k+1)\tag{5.7.514}$$

For $m\rightarrow+\infty$ (...) all the terms are of then of the order of m. Then we have:

$$m(m-1)\ldots(m-k+1)\cong m^k\tag{5.7.515}$$

For the third term, a identical development to the previous one provides (for sure we need that also $n\rightarrow+\infty$ (...)):

$$\frac{(n-m)!}{(p-k)!((n-m)-(p-k))!}\cong(n-m)^{p-k}\tag{5.7.516}$$

And for sure... we can debate therefore about $n-m$ when both terms tends to infinity...

Ditto for the fourth term:

$$\frac{(n-p)!}{n!}\cong n^{-p}\tag{5.7.517}$$

In conclusion we have:

$$\frac{C_k^m C_{p-k}^{n-m}}{C_p^n}\underset{n,m\rightarrow+\infty}{=}C_p^k\frac{m^k(n-m)^{p-k}}{n^p}\tag{5.7.518}$$

We change the notation by writing p (the number of individuals drawn) as being N. We get then:

$$\frac{C_k^m C_{N-k}^{n-m}}{C_N^n}\underset{n,m\rightarrow+\infty}{=}C_k^N\frac{m^k(n-m)^{N-k}}{n^N}\tag{5.7.519}$$

We make another change of notation by writing b the black balls and w the white balls. We get then:

$$\frac{C_k^b C_{N-k}^{n-b}}{C_N^n}\underset{n,b\rightarrow+\infty}{=}C_k^N\frac{b^k(n-b)^{N-k}}{n^N}=C_k^N\frac{b^k w^{N-k}}{n^N}\tag{5.7.520}$$

Finally, we note p the proportion of black balls and q that of white balls in the lot. We then get:

$$\frac{C_k^{np}C_{N-k}^{n-np}}{C_N^n} \underset{np\to+\infty}{=} C_k^N\frac{(np)^k(nq)^{N-k}}{n^N}=C_k^N(np)^k(nq)^{N-k}n^{-N}=C_k^Np^kq^{N-k} \tag{5.7.521}$$

We find out the binomial distribution! In practice, it is common to approximate the hypergeometric distribution with a binomial distribution when the ratio of the number of individuals from the total number of individuals is less than 10% (that is to say when the sample is 10 times smaller than the whole population). It follows that the hypergeometric distribution tends also (as we will show later) to a Normal distribution when the population tends to infinity and that the sample is small.

In practice, Monte Carlo simulations with testing adjustments (see later in this chapter) have shown that the hypergeometric distribution could be approximated by a Normal distribution (very important case in contingency statistical tests that we will study further below in this section) if the following three conditions are met simultaneously:

$$k>9\frac{n-m}{m}\qquad k>9\frac{m}{n-m}\qquad k<\frac{n}{10} \tag{5.7.522}$$

Thus graphically and approximately...:

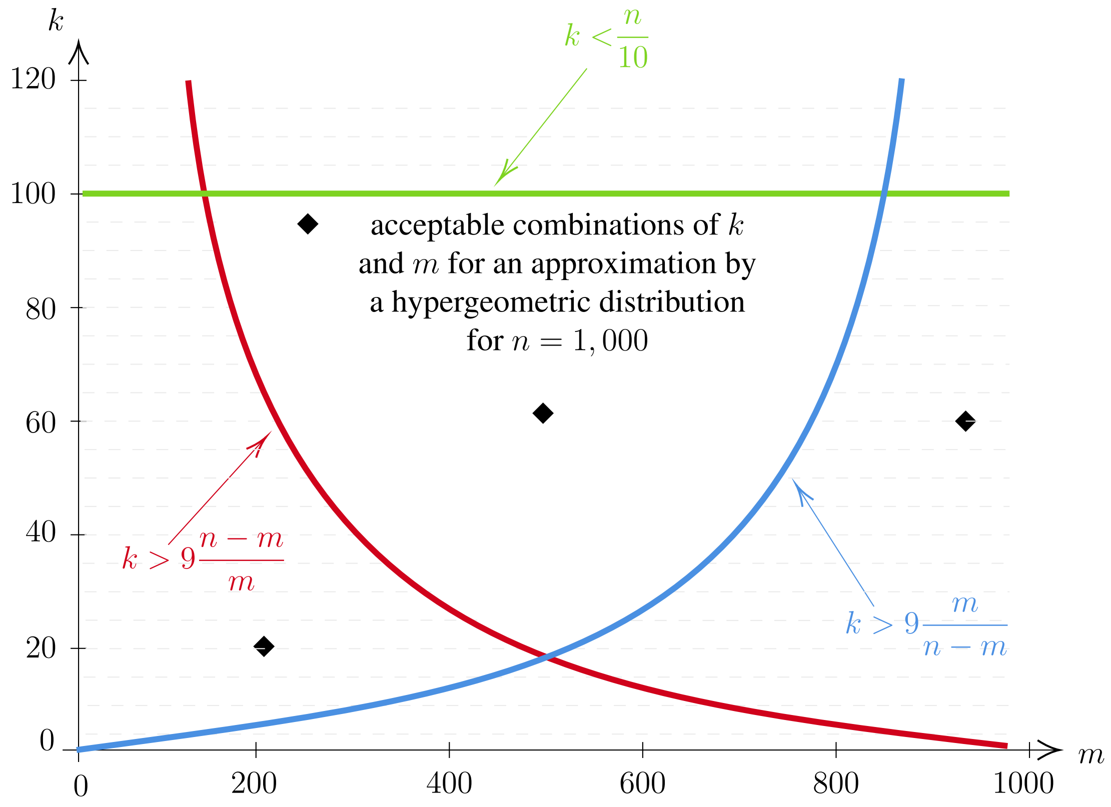

Figure 5.125: Conditions of application of the approximation by a Normal distribution

Thus:

$$\mathcal{H}(k,m,n)\cong\mathcal{N}(\mu,\sigma)=\mathcal{N}\left(k\frac{m}{n},\sqrt{\frac{krs(n-k)}{n^2(n-1)}}\right)=\mathcal{N}\left(k\frac{m}{n},\sqrt{\frac{kmm'(n-k)}{n^2(n-1)}}\right) \tag{5.7.523}$$

5.7.6.7 Multinomial Distribution

The multinomial distribution (so named because it involves several times the binomial coefficient) is a law applicable to n distinguishable events, each with a given probability, which occur one or more times and it is not necessarily ordered. This is a frequent case in marketing research and that will be useful to build the statistical McNemar test that we will study much later (see further below page 1264) and also the Multinomial logistic regression (see section Numerical Methods page 6477).

The multinomial law is a generalization of the binomial law applicable for example to n trials of a six-sided die but with the difference that probabilities are not equal!

More technically, consider the space of events $\Omega = \{1, 2, \ldots, m\}$ with the probabilities $P(\{i\}) = p_i, i = 1, 2, \ldots, n$. We take n times a given element of Ω with replacement with the probability $p_i, i = 1, 2, \ldots, n$. We will search what is the probability of getting in a non-necessarily ordered way the event 1, k_1 times, event 2, k_2 times and this on a sequence of n drawings.

Remark

This is equivalent to the study of a sampling with replacement AND constraints on the occurrences! So without constraints we will see with an example that we fall back on a sampling with simple replacement.

We know that (see section Probabilities page 528) if we take a set of events with multiple outcomes, then the different combinations of sequences we can get taking p selected elements among n is given by:

$$C_p^n = \frac{n!}{p!(n-p)!} \tag{5.7.524}$$

We have therefore:

$$C_{k_1}^n = \frac{n!}{k_1!(n-k_1)!} \tag{5.7.525}$$

different ways to get k_1 times a given event. Thus an associated probability of (it's the binomial distribution):

$$P(n, k_1) = C_{k_1}^n p_1^{k_1} q_1^{n-k_1} = C_{k_1}^n p_1^{k_1} (1-p_1)^{n-k_1} \tag{5.7.526}$$

Now comes the particularity of the multinomial distribution!: there are no failures in contrast to the binomial distribution. Each "pseudo-failure" can be considered as a subset draw of k_2 items from the $n - k_1$ remaining elements.

Thus the term:

$$C_{k_1}^n p_1^{k_1} q_1^{n-k_1} \tag{5.7.527}$$

will be written on the whole experience if we consider a particular case limited to two types of events:

$$C_{k_1}^n p_1^{k_1} q_1^{n-k_1} := C_{k_1}^n p_1^{k_1} (C_{k_2}^{n-k_1} p_2^{k_2}) \tag{5.7.528}$$

so with:

$$C_{k_2}^{n-k_1}=\frac{(n-k_1)!}{k_2!((n-k_1)-k_2)!} \tag{5.7.529}$$

which gives us the number of different times to get k_2 times a second event because in the whole sequence of n elements k_1 of them have already been taken so have now only $n-k_1$ remaining on which we can get the k_2 desired.

These relations then show us that this is a situation where each event probability is considered as a binomial (hence its name ...).

So we have in the case of two sets of t-uples:

$$\begin{aligned}C_{k_1}^{n}p_1^{k_1}C_{k_2}^{n-k_1}p_2^{k_2}&=C_{k_1}^{n}C_{k_2}^{n-k_1}p_1^{k_1}p_2^{k_2}=\frac{n!}{k_1!(n-k_1)!}\frac{(n-k_1)!}{k_2!((n-k_1)-k_2)!}p_1^{k_1}p_2^{k_2}\\&=\frac{n!}{k_1!k_2!}\frac{1}{n-k_1-k_2}p_1^{k_1}p_2^{k_2}\end{aligned} \tag{5.7.530}$$

and because:

$$-k_1-k_2=-n \tag{5.7.531}$$

we get:

$$P=\frac{n!}{k_1!k_2!}\frac{1}{0!}p_1^{k_1}p_2^{k_2}=\frac{n!}{k_1!k_2!}p_1^{k_1}p_2^{k_2} \tag{5.7.532}$$

and we see that the construction of this distribution therefore requires that:

$$\sum_i p_i=1 \qquad \sum_i k_i=n \tag{5.7.533}$$

Thus, by induction we have the probability $\mathcal{M}$ we were looking for and named the "Multinomial function" and using the previous relation given by:

$$\boxed{\mathcal{M}(\vec{k},\vec{p},m)=\frac{n!}{\prod\limits_{i=1}^{m}k_i!}\prod_{i=1}^{m}p_i^{k_i}=\frac{\left(\sum\limits_{i=1}^{m}k_i\right)!}{\prod\limits_{i=1}^{m}k_i!}\prod_{i=1}^{m}p_i^{k_i}} \tag{5.7.534}$$

In other words if there are m random variables, i.e. X_i, $i\in[1,n]$, where X_i represents the number of occurrences of item i in a choice of n items, with entry i in the vector of probabilities $\vec{p}$, p_i giving the probability of drawing item i. The probability of selecting k_i of item $k_1\ldots k_m$ of item m is then given by $\mathcal{M}(\vec{k},\vec{p},m)$ above (if this explanation is not clear, see the example further below!).

Remark

Note that if $m=2$ then the above relation becomes:

$$\mathcal{M}=\frac{(k_1+k_2)!}{k_1!k_2!}p_1^{k_1}p_2^{k_2} \tag{5.7.535}$$

But as $k_1+k_2=n$ then:

$$\mathcal{M}=\frac{n!}{k_1!(n-k_1)!}p_1^{k_1}p_2^{n-k_1} \tag{5.7.536}$$

and as $p_1+p_2=1$ we finally have:

$$\mathcal{M}=\frac{n!}{k_1!(n-k_1)!}p_1^{k_1}(1-p_1)^{n-k_1} \tag{5.7.537}$$

We recognize here the binomial distribution!

In a spreadsheet software Microsoft® Excel® 11.8346, the term:

$$\frac{\left(\sum\limits_{i=1}^{m} k_i\right)!}{\prod\limits_{i=1}^{m} k_i!} \tag{5.7.538}$$

is named "multinomial coefficient" and is available under the name of the function `MULTINOMIAL( )`. In the literature we also find this term sometimes under the following respective notations:

$$\binom{k_1+k_2+\ldots+k_m}{k_1,k_2,\ldots,k_m} \qquad \binom{n}{k_1,k_2,\ldots,k_m} \tag{5.7.539}$$

Which gives then for the expression of the multinomial distribution:

$$\mathcal{M}(\vec{k},\vec{p},m)=\binom{n}{k_1,k_2,\ldots,k_m}\prod_{i=1}^{m}p_i^{k_i} \tag{5.7.540}$$

Theorem 5.47. We will show now that the multinomial distribution is effectively a probability distribution (because we could doubt ...). If this is the case, as we know it, the sum of the probabilities must be equal to 1.

Proof 5.47.1. Let us recall that we proved the binomial theorem (see section Calculus page 1364):

$$(x+y)^n=\sum_{k=0}^{n}C_k^n x^k y^{n-k} \tag{5.7.541}$$

Now do a little bit of notation:

$$(x_1+x_2)^n=\sum_{k_1=0}^{n}C_k^n x_1^{k_1}x_2^{n-k_1}=\sum_{k_1=0}^{n}\frac{n!}{k_1!(n-k_1)!}x_1^{k_1}x_2^{n-k_1} \tag{5.7.542}$$

and this time a change of variables:

$$(x_1+x_2)^n=\sum_{k_1=0}^{n}C_k^n x_1^{k_1}x_2^{n-k_1}=\sum_{k_1=0}^{n}\frac{n!}{k_1!k_2!}x_1^{k_1}x_2^{k_2} \tag{5.7.543}$$

This last relation (which is a special case with two terms of the "multinomial theorem") will be useful to us to show that the multinomial distribution is effectively a probability distribution. We also take the special case with two groups of drawing:

$$\mathcal{M}(\vec{k},\vec{k},m)=\frac{n!}{\prod\limits_{i=1}^{m}k_i!}\prod_{i=1}^{m}p_i^{k_i}=\frac{n!}{k_1!k_2!}p_1^{k_1}p_2^{k_2} \tag{5.7.544}$$

which can is also written by the construction of the multinomial distribution:

$$\mathcal{M}=\frac{n!}{k_1!(n-k_1)!}p_1^{k_1}p_2^{n-k_1} \tag{5.7.545}$$

and therefore, the sum must be equal to the unit such that:

$$\sum_{k_1=0}^{n}\frac{n!}{k_1!(n-k_1)!}p_1^{k_1}p_2^{n-k_1}=1 \tag{5.7.546}$$

To check this we use the multinomial theorem shown above:

$$(p_1+p_2)^n=\sum_{k_1=0}^{n}\frac{n!}{k_1!k_2!}p_1^{k_1}p_2^{k_2} \tag{5.7.547}$$

However, by construction of the multinomial sum of probabilities is unitary, we have effectively:

$$(p_1+p_2)^n=(1)^n=1=\sum_{k_1=0}^{n}\frac{n!}{k_1!(n-k_1)!}p_1^{k_1}p_2^{n-k_1} \tag{5.7.548}$$

■ Q.E.D.

✍**Examples:**

E1. We launch an unbiased die 12 times. The probability that all 6 faces appear the same number of times (not necessarily consecutively!) is given by:

$$\mathcal{M}=\frac{n!}{\prod\limits_{i=1}^{m}k_i!}\prod_{i=1}^{m}p_i^{k_i}=\frac{12!}{\prod\limits_{i=1}^{6}2!}\prod_{i=1}^{6}\left(\frac{1}{6}\right)^2=\frac{12!}{2^6 6^{12}}=0.34\% \tag{5.7.549}$$

where we see well that m is the number of successes.

E2. We launch an unbiased die 12 times. The probability that a single unique face appears

12 times (hence the "1" appears 12 times, or the "2" or the "3", etc.) is given by:

$$\mathcal{M}=\frac{n!}{\prod\limits_{i=1}^{m}k_i!}\prod_{i=1}^{m}p_i^{k_i}=\frac{12!}{\prod\limits_{i=1}^{1}12!}\prod_{i=1}^{1}\left(\frac{1}{6}\right)^{12}=\frac{12!}{6^{12}} \tag{5.7.550}$$

So we end up with this last example known a being a binomial distribution result.

Let us recall that we have proved just earlier above (we just changes the notation a bit):

$$\mathcal{M}(\vec{x},\vec{p},r)=\frac{n!}{\prod\limits_{i=1}^{r}x_i!}\prod_{i=1}^{r}p_i^{x_i}=\frac{n!}{x_1!x_2!\ldots x_r!}p_1^{x_1}p_2^{x_2}\ldots p_r^{x_r} \tag{5.7.551}$$

And then we have obviously:

$$\sum_{\substack{x_1,x_2,\ldots,x_r\\ \sum_{i=1}^{r}x_i=n}}\frac{n!}{x_1!x_2!\ldots x_r!}p_1^{x_1}p_2^{x_2}\ldots p_r^{x_r}=1 \tag{5.7.552}$$

The mean of the multinomial distribution is in fact a mean of vector. But as the mean of a vector is equal to the mean of its components we want to calculate $\text{E}(x_i)$. For this, without loss of generality, let us calculate $\text{E}(x_1)$. To do this let us recall that by definition of the mean:

$$\text{E}(x_1)=\sum_{x_1=0}^{n}x_1P(X_1=x_1) \tag{5.7.553}$$

But for $x_1=0$ the corresponding terms is equal to zero. Then we can directly write:

$$\text{E}(x_1)=\sum_{x_1=1}^{n}x_1P(X_1=x_1) \tag{5.7.554}$$

Now as the sum already acts on the term $P(X_1=x_1)$, for that latter we have only to sum on all terms excepted x_1 such that:

$$\begin{aligned}\text{E}(x_1)&=\sum_{x_1=1}^{n}x_1\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^{r}x_i=n-x_1}}\frac{n!}{x_1!x_2!\ldots x_r!}p_1^{x_1}p_2^{x_2}\ldots p_r^{x_r}\\&=\sum_{x_1=1}^{n}\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^{r}x_i=n-x_1}}\frac{n!}{(x_1-1)!x_2!\ldots x_r!}p_1p_1^{x_1-1}p_2^{x_2}\ldots p_r^{x_r}\end{aligned} \tag{5.7.555}$$

Now we make the following change of variables $x_1'=x_1-1$. Then:

$$\begin{aligned}\mathrm{E}(x_1)&=\sum_{x_1'=0}^{n-1}\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^{r}x_i=n-x_1'+1}}\frac{n!}{x_1'!x_2!\ldots x_r!}p_1p_1^{x_1'}p_2^{x_2}\ldots p_r^{x_r}\\&=\sum_{x_1'=0}^{n-1}\sum_{\substack{x_2,\ldots,x_r\\ x_1'+x_2+\ldots+x_r=n-1}}\frac{n!}{x_1'!x_2!\ldots x_r!}p_1p_1^{x_1'}p_2^{x_2}\ldots p_r^{x_r}\\&=np_1\sum_{x_1'=0}^{n-1}\sum_{\substack{x_2,\ldots,x_r\\ x_1'+x_2+\ldots+x_r=n-1}}\frac{(n-1)!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'}p_2^{x_2}\ldots p_r^{x_r}\end{aligned}\tag{5.7.556}$$

But the second summation is knows to us! Indeed, it's the cumulated probability on all $n-1$ (instead of the classical n). And that one is equal to 1. Therefore we have:

$$\begin{aligned}\mathrm{E}(x_1)&=np_1\sum_{x_1'=0}^{n-1}\underbrace{\sum_{\substack{x_2,\ldots,x_r\\ x_1'+x_2+\ldots+x_r=n-1}}\frac{(n-1)!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'}p_2^{x_2}\ldots p_r^{x_r}}_{=1}\\&=np_1\sum_{x_1'=0}^{n-1}1=np_i\end{aligned}\tag{5.7.557}$$

Therefore:

$$\mathrm{E}(\vec{x})=n\vec{p}\tag{5.7.558}$$

Now let us see the variance (it's also a vector of variance in fact!). The idea is quite the same as for the mean. First we will use the Huygens relation:

$$\mathrm{V}(x_i)=\mathrm{E}(x_i^2)-\mathrm{E}(x_i)^2=\mathrm{E}(x_i^2)-(np_i)^2\tag{5.7.559}$$

So only the first term $\mathrm{E}(x_i^2)$ is unknown to us. Without loss of generality, and again by taking the definition of the expected mean, let us consider:

$$\begin{aligned}\mathrm{E}(x_1^2)&=\sum_{x_1=0}^{n}x_1^2P(X_1=x_1)=\sum_{x_1=1}^{n}x_1^2P(X_1=x_1)\\&=\sum_{x_1=1}^{n}x_1^2\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^{r}x_i=n-x_1}}\frac{n!}{x_1!x_2!\ldots x_r!}p_1^{x_1}p_2^{x_2}\ldots p_r^{x_r}\\&=\sum_{x_1=1}^{n}x_1\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^{r}x_i=n-x_1}}\frac{n!}{(x_1-1)!x_2!\ldots x_r!}p_1^{x_1}p_2^{x_2}\ldots p_r^{x_r}\end{aligned}\tag{5.7.560}$$

Let us do now the change of variable:

$$x_1'=x_1-1\Leftrightarrow x_1=x_1'+1\tag{5.7.561}$$

Therefore:

$$
\begin{aligned}
\mathrm{E}(x_1^2) &= \sum_{x_1'=0}^{n-1}(x_1'+1)\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^r x_i=n-x_1'-1}}\frac{n!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'+1}p_2^{x_2}\ldots p_r^{x_r}\\
&=\sum_{x_1'=0}^{n-1}x_1'\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^r x_i=n-x_1'-1}}\frac{n!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'+1}p_2^{x_2}\ldots p_r^{x_r}+\sum_{x_1'=0}^{n-1}\sum_{\substack{x_2,\ldots,x_r\\ \sum_{i=2}^r x_i=n-x_1'-1}}\frac{n!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'+1}p_2^{x_2}\ldots p_r^{x_r}\\
&=np_1\sum_{\substack{x_1',\ldots,x_r\\ x_1'+\ldots+x_r=n-1}}\frac{(n-1)!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'}p_2^{x_2}\ldots p_r^{x_r}+np_1\sum_{\substack{x_1',\ldots,x_r\\ x_1'+\ldots+x_r=n-1=n-1}}\frac{(n-1)!}{x_1'!x_2!\ldots x_r!}p_1^{x_1'}p_2^{x_2}\ldots p_r^{x_r}\\
&=np_1\begin{pmatrix}\text{expected valued of}\\ \text{multinomial with } n-1\end{pmatrix}+np_1\underbrace{\begin{pmatrix}\text{cumulated probability}\\ \text{of a multinomial } n-1\end{pmatrix}}_{=1}\\
&=np_1\left((n-1)p_1\right)+np_1
\end{aligned}
\tag{5.7.562}
$$

So finally:

$$
\mathrm{V}(x_i)=\mathrm{E}(x_i^2)-\mathrm{E}(x_i)^2=\left[np_1\left((n-1)p_1\right)+np_1\right]-(np_i)^2=np_1(1-p_1)
\tag{5.7.563}
$$

5.7.6.8 Poisson Distribution

For some rare events, the probability p is very small and tends to zero. However, the average value np tends to a fixed value as n tends to infinity.

We start from a binomial distribution with mean $\mu = np$ that we will assume finite when n tends to infinity.

The probability of k successes after n trials is (Binomial distribution):

$$\mathcal{B}(n,k) = C_k^n p^k (1-p)^{n-k} = C_k^n p^k q^{n-k} = \binom{n}{k} p^k q^{n-k} \tag{5.7.564}$$

By writing $p = \dfrac{m}{n}$ (where m will be temporarily the new notation for the mean according to $\mu = np$), this expression can be rewritten as:

$$\mathcal{B}(n,k) = \binom{n}{k} p^k q^{n-k} = \frac{n!}{k!(n-k)!}\left(\frac{n}{m}\right)^k \left(1-\frac{m}{n}\right)^{n-k} \tag{5.7.565}$$

By grouping the terms, we can put the value $\mathcal{B}(n,k)$ under the form:

$$\mathcal{B}(n,k) = \frac{m^k}{k!}\left(1-\frac{m}{n}\right)^n \frac{n!}{(n-k)!n^k\left(1-\dfrac{m}{n}\right)^k} \tag{5.7.566}$$

We recognize that when n tends to infinity, the second factor of the product has for limit $e^{-\mu}$ (see Functional Analysis page 2289). The third factor, since we are interested to the small values of k (the probability of success is very small), its limit for n tending to infinity is equal to 1.

This technique of passing to the limit is sometimes named in this context: the "Poisson limit theorem".

So we get the "Poisson distribution" (or "Poisson law"), also sometimes named the "law of rare events" therefore given by:

$$\boxed{\mathcal{P}(\mu,k) = \frac{\mu^k}{k!}e^{-\mu}} \tag{5.7.567}$$

which can be obtained in Microsoft® Excel® 11.8346 with the function `POISSON( )` and in practice and the specialized literature is often indicated by the letter u.

It is indeed a probability distribution since using the Taylor series (see section Sequences and Series page 1703), we show that the sum of the cumulative probabilities is:

$$\sum_{k=0}^{+\infty}\frac{\mu^k}{k!}e^{-\mu} = e^{-\mu}\sum_{k=0}^{+\infty}\frac{\mu^k}{k!} = e^{-\mu}e^{\mu} = 1 \tag{5.7.568}$$

Remark

We will frequently encounter this distribution in different sections of the book such as in the study of preventive maintenance in the section of Industrial Engineering page 8716 or in the section of Quantitative Management for the study of queuing theory page 8141 (the reader can refer to them for interesting and pragmatic examples) and finally in the field of life and non-life insurance.

Here is a plot example of the Poisson distribution and cumulative distribution function with parameter $\mu = 3$:

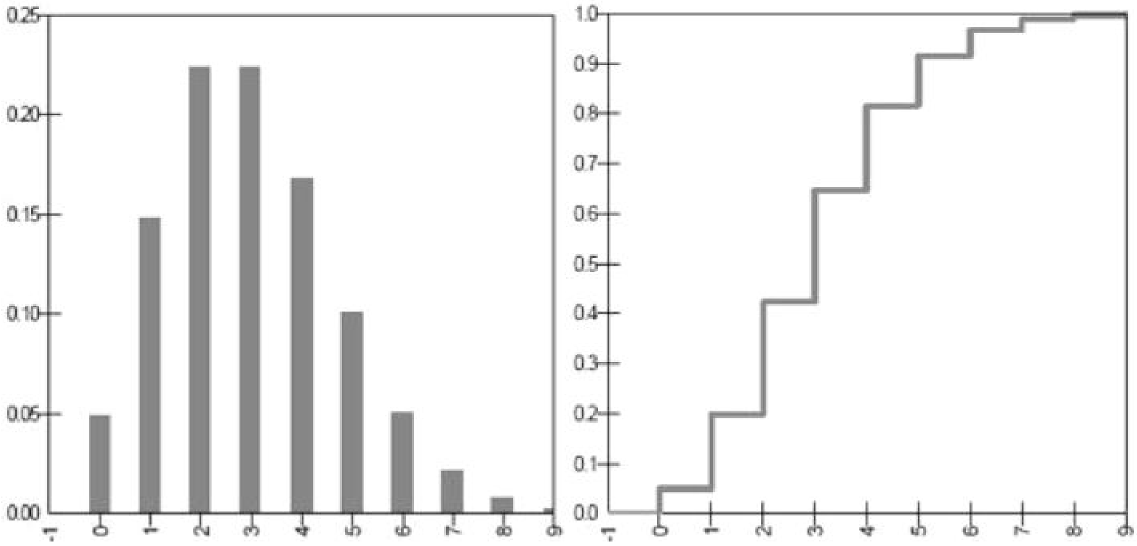

Figure 5.126: Poisson law $\mathcal{P}$ (mass and cumulative distribution function)

This distribution is important because it describes many processes whose probability is small and constant. It is often used in the "queuing theory" (waiting time), acceptability and reliability test and statistical quality control. Among other things, it applies to processes such as the emission of light quanta by excited atoms, the number of red blood cells seen under the microscope, the number of incoming calls to a call center. The Poisson distribution is valid for many observations in nuclear and particle physics.

The mean (average) of the Poisson distributions is (we use the Taylor series of the exponential):

$$\mu = \mathrm{E}(k) = \sum_{k=0}^{+\infty} k\mathcal{P}(\mu, k) = \sum_{k=0}^{+\infty} k\frac{\mu^k}{k!}e^{-\mu} = e^{-\mu}\mu\sum_{k=1}^{+\infty}\frac{\mu^{k-1}}{(k-1)!} = e^{-\mu}\mu e^{\mu} = \mu \tag{5.7.569}$$

and gives the average number of times that you get the desired outcome.

This result may seem confusing .... the mean is expressed by the mean?? Yes must simply not forget that it is given since the beginning by:

$$\mu = np \tag{5.7.570}$$

Remark

For more details the reader may also refer to the subsection on "estimators" page 818.

The variance of the Poisson distribution function is itself given by (again we use the Taylor series):

$$\begin{aligned}
\sigma^2=\mathrm{V}(k)&=\sum_{k=0}^{+\infty}[k-\mu^2]P_k=\sum_{k=0}^{+\infty}[k-\mu^2]\frac{\mu^k}{k!}e^{-\mu}\\
&=\sum_{k=0}^{+\infty}k^2\frac{\mu^k}{k!}e^{-\mu}-\sum_{k=0}^{+\infty}2k\mu\frac{\mu^k}{k!}e^{-\mu}+\sum_{k=0}^{+\infty}\mu^2\frac{\mu^k}{k!}e^{-\mu}\\
&=\sum_{k=0}^{+\infty}k^2\frac{\mu^k}{k!}e^{-\mu}-2\mu\mu\sum_{k=1}^{+\infty}\frac{k\mu^{k-1}}{k(k-1)!}e^{-\mu}+\mu^2\sum_{k=0}^{+\infty}\frac{\mu^k}{k!}e^{-\mu}\\
&=\sum_{k=0}^{+\infty}k^2\frac{\mu^k}{k!}e^{-\mu}-2\mu^2\sum_{k=1}^{+\infty}\frac{\mu^{k-1}}{(k-1)!}e^{-\mu}+\mu^2\cdot 1=\sum_{k=0}^{+\infty}k^2\frac{\mu^k}{k!}e^{-\mu}-2\mu^2+\mu^2\\
&=e^{-\mu}\sum_{k=0}^{+\infty}k^2\frac{\mu^k}{k!}-\mu^2=\mu e^{-\mu}\sum_{k=1}^{+\infty}k\frac{\mu^{k-1}}{(k-1)!}-\mu^2\\
&\underset{s=k-1}{=}\mu e^{-\mu}\sum_{s=0}^{+\infty}(s+1)\frac{\mu^s}{s!}-\mu^2=\mu e^{-\mu}\left(\sum_{s=0}^{+\infty}s\frac{\mu}{s!}+\sum_{s=0}^{+\infty}\frac{\mu^s}{s!}\right)-\mu^2\\
&=\mu e^{-\mu}\left(\mu\sum_{s=1}^{+\infty}\frac{\mu^{s-1}}{(s-1)!}+e^{\mu}\right)-\mu^2=\mu e^{-\mu}(\mu e^{\mu}+e^{\mu})-\mu^2\\
&=\mu e^{-\mu}\mu e^{\mu}+\mu e^{-\mu}e^{\mu}-\mu^2=\mu^2-\mu-\mu^2=\mu
\end{aligned}\tag{5.7.571}$$

always with:

$$\mu=np\tag{5.7.572}$$

The important fact for the Poisson distribution is that the variance that is equal to the mean is named the "equidispersion property of the Poisson distribution". This is a property often used in practice as an indicator to identify whether the data (with discrete support) are distributed according to a Poisson distribution.

The theoretical laws of statistical distributions are determined assuming completion of an infinite number of measurements. It is obvious that we can only perform in practice a finite number N. Hence the utility to establish correspondence between the theoretical and experimental values. For the experimental values we obviously obtain only an approximation whose validity is, however, often accepted as sufficient.

Now we will prove an important property of the Poisson distribution in the field of engineering and statistics that we name "stability by addition". The idea is as follows:

Let X and Y be two independent random variables with Poisson distribution of respective parameters λ and μ. We want to ensure that their sum is also a Poisson distribution:

$$X+Y=P_{\lambda+\mu}\tag{5.7.573}$$

See this:

$$P(X+Y=k)=\sum_{i=0}^{k}P\left[(X=i)\cap(Y=k-i)\right]=\sum_{i=0}^{k}P(X=i)P(Y=k-i) \quad (5.7.574)$$

because the events are independent. Then we have:

$$\begin{aligned}P(X+Y=k)&=\sum_{i=0}^{k}P(X=i)P(Y=k-i)=\sum_{i=0}^{k}\frac{\lambda^i e^{-\lambda}}{i!}\frac{\mu^{k-i}e^{\mu}}{(k-i)!}\\&=\frac{e^{-(\lambda+\mu)}}{k!}\sum_{i=0}^{k}\frac{k!}{i!(k-i)!}\lambda^i\mu^{k-i}\end{aligned} \quad (5.7.575)$$

However, by applying the binomial theorem (see section Calculus page 1364):

$$\sum_{i=0}^{k}\frac{k!}{i!(k-i)!}\lambda^i\mu^{k-i}=\sum_{i=0}^{k}C_i^k\lambda^i\mu^{k-i}=(\lambda+\mu)^k \quad (5.7.576)$$

So in the end:

$$P(X+Y=k)=(\lambda+\mu)^k\frac{e^{-(\lambda+\mu)}}{k!} \quad (5.7.577)$$

and therefore the Poisson distribution is stable by addition. So any Poisson distribution where the parameter is verbatim indefinitely dividable into a finite or infinite sum of independent Poisson distributions.

For the people who may not have access to a spreadsheet or statistical software here are some useful tables:

5.7.6.9 Normal & Gauss-Laplace Distribution

This is the most important function of distribution in the field of statistics following a famous theorem named the "central limit theorem", which as we will see later, permits to prove (among other things) that any sum of independent identically distributed random variables with a finite mean and variance converges to a Laplace-Gaussian function (Normal distribution).

It is therefore very important to focus your attention on the developments that will be presented right now!

Let start from a binomial function and make tender the number of trials n to infinity. If p is set from the beginning , the mean $\mu = np$ also tends to infinity, furthermore the standard deviation $\sigma = npq$ also tends to infinity.

Remark

The case where p varies and tends to 0 while keeping fixed the mean has already been studied during the study of the Poisson function.

If we want to calculate the limit of the binomial function, it will then be necessary to make a change of origin, which stabilizes the mean, to 0 for example, and a change of unit change that stabilizes the standard deviation to 1 for example.

Let us now denote by $P_n(k)$ the binomial probability of k success and let's see first how $P_n(k)$ vary with k and calculate the difference:

$$\begin{aligned} P_n(k+1)-P_n(k) &= \binom{n}{k+1}p^{k+1}q^{n-k-1}-\binom{n}{k}p^kq^{n-k} \\ &= \binom{n}{k}p^kq^{n-k}\left(\frac{(n-k)p}{(k+1)q}-1\right)=P_n(k)\frac{np-k-q}{(k+1)q} \end{aligned} \tag{5.7.578}$$

We conclude that $P_n(k)$ is an increasing function of k, as $np-k-q$ is positive (for n, p and q fixed). Too see it, just take a few values (of the right term of the equality) or to observe the graph of the binomial distribution function, remembering that:

$$\mu = np \tag{5.7.579}$$

As $q<1$ it is therefore evident that the value of k close to the mean $\mu = np$ of the binomial distribution is the maxima of $P_n(k)$.

On the other hand the difference $P_n(k+1)-P_n(k)$ is the increase rate of the function $P_n(k)$. We can then write:

$$\frac{\Delta P_n(k)}{\Delta k}=\frac{P_n(k+1)-P_n(k)}{(k+1)-k} \tag{5.7.580}$$

as being the slope of the function.

We now define a new random variable such that its average is zero (negligible variations) and its standard deviation equal to the unit (this will be a centered-reduced variable in other words). Then we have:

$$x=\frac{k-np}{\sqrt{npq}} \tag{5.7.581}$$

Then we also have with this new random variable:

$$\Delta x=\frac{(k+1)-np}{\sqrt{npq}}-\frac{k-np}{\sqrt{npq}}=\frac{[(k+1)-np]-(k-np)}{\sqrt{npq}} \tag{5.7.582}$$

Let us denote $F(x)$ as being $P_n(k)$ calculated using the new random variable with zero mean and unit standard deviation which we seek the expression when n tends to infinity.

Let's go back to:

$$\frac{\Delta P_n(k)}{\Delta k}=\frac{np-k-q}{(k+1)q}P_n(k)=\frac{-(k-np)-q}{(k+1)q}P_n(k) \tag{5.7.583}$$

To simplify the study of this relation when n tends to infinity and k to mean $\mu=np$, multiply both sides by $npq/\sqrt{npq}$:

$$\frac{\Delta P_n(k)}{\Delta k}\frac{npq}{\sqrt{npq}}=\frac{np-k-q}{(k+1)q}\frac{npq}{\sqrt{npq}}P_n(k)=\frac{-(k-np)-q}{(k+1)q}\frac{npq}{\sqrt{npq}}P_n(k) \tag{5.7.584}$$

We rewrite now the right-hand side of this equality. Then we get:

$$\frac{-(k-np)-q}{(k+1)}\frac{np}{\sqrt{npq}}P_n(k)=\frac{[-(k-np)-q]np}{(k+1)\sqrt{npq}}P_n(k) \tag{5.7.585}$$

And now let us rewrite the left term of the prior-previous relation. We then get:

$$\begin{aligned}\frac{\Delta P_n(k)}{\Delta k}\frac{npq}{\sqrt{npq}}&=\frac{\Delta P_n(k)}{(k+1)-1}\frac{npq}{\sqrt{npq}}=\frac{\Delta P_n(k)}{[(k+1)-np]-(k-np)}\frac{npq}{\sqrt{npq}}\\&=\frac{\Delta P_n(k)}{\dfrac{[(k+1)-np]-(k-np)}{\sqrt{npq}}}\frac{npq}{\sqrt{npq}\sqrt{npq}}\\&=\frac{\Delta P_n(k)}{\dfrac{[(k+1)-np]-(k-np)}{\sqrt{npq}}}=\frac{\Delta P_n(k)}{\Delta x}\end{aligned} \tag{5.7.586}$$

After passing to the limit for n tending to infinity we have in a first time for the denominator of the second term of the prior-previous relation:

$$\frac{[-(k-np)-q]np}{(k+1)\sqrt{npq}}P_n(k) \tag{5.7.587}$$

the following simplification:

$$(k+1)\sqrt{npq}\underset{n\rightarrow+\infty}{=}k\sqrt{npq} \tag{5.7.588}$$

Thus:

$$\frac{-[(k-np)+q]np}{k\sqrt{npq}}P_n(k)=-\frac{k-np}{k\sqrt{npq}}npP_n(k)-\frac{qnp}{k\sqrt{npq}}P_n(k) \tag{5.7.589}$$

and in a second time, taking into account that the considered values of k are then in the neighborhood of the mean np, we get:

$$\frac{k-np}{k\sqrt{npq}}np=\frac{np}{k}\frac{k-np}{\sqrt{npq}}\underset{n\rightarrow+\infty}{\cong}\frac{k-np}{\sqrt{npq}}=x \tag{5.7.590}$$

and:

$$\frac{qnp}{k\sqrt{npq}}\underset{n\rightarrow+\infty}{\cong}\frac{qnp}{np\sqrt{npq}}=\frac{q}{\sqrt{npq}}\underset{n\rightarrow+\infty}{\cong}0 \tag{5.7.591}$$

Thus:

$$\frac{-[(k-np)+q]np}{k\sqrt{npq}}\underset{n\rightarrow+\infty}{\cong}-x \tag{5.7.592}$$

and as:

$$P_n(k)\underset{n\rightarrow+\infty}{:=}F(x) \tag{5.7.593}$$

where $F(x)$ represents (awkwardly) for the few lines that follow, the density function as n tends to infinity.

Finally we have:

$$\frac{\mathrm{d}F(x)}{\mathrm{d}x}=-xF(x) \tag{5.7.594}$$

This relation can also be rewritten rearranging the terms:

$$\frac{1}{F(x)}\mathrm{d}F(x)=-x\mathrm{d}x \tag{5.7.595}$$

and by integrating both sides of this equality we get (see section Differential and Integral Calculus page 1497):

$$\ln(F(x))=-\frac{x^2}{2}+c^{te} \tag{5.7.596}$$

The following function is a solution of the above equation:

$$F(x)=\lambda e^{-\frac{x^2}{2}} \tag{5.7.597}$$

Effectively:

$$\ln\left(\lambda e^{-\frac{x^2}{2}}\right)=\ln(\lambda)+\ln\left(e^{-\frac{x^2}{2}}\right)=c^{te}+\left(-\frac{x^2}{2}\right)=-\frac{x^2}{2}+c^{te} \tag{5.7.598}$$

The constant is determined by the condition that:

$$\int\limits_{-\infty}^{+\infty}F(x)\mathrm{d}x \tag{5.7.599}$$

which represents the sum of all probabilities, that mus be equal to 1. We prove for this that we need to have:

$$\lambda=\frac{1}{\sqrt{2\pi}} \tag{5.7.600}$$

Proof 5.47.2. We have:

$$\int\limits_{-\infty}^{+\infty} e^{\frac{-x^2}{2}}\mathrm{d}x=\int\limits_{-\infty}^{+\infty} e^{\left(-\frac{x}{\sqrt{2}}\right)^2}\mathrm{d}x=\sqrt{2}\int\limits_{-\infty}^{+\infty} e^{-z^2}\mathrm{d}z \tag{5.7.601}$$

So let us focus on the last term of this equality named the "Gauss integral" or "Gaussian integral" (in fact the case below is a special case of that integral) or also "probability integral". Thus:

$$I=\int\limits_{-\infty}^{+\infty} e^{-x^2}\mathrm{d}x=2\int\limits_{0}^{+\infty} e^{-x^2}\mathrm{d}x \tag{5.7.602}$$

since e^{-x^2} is an even function (see section Functional Analysis page 2212). Now we write the square of the integral as follows:

$$I^2=4\lim_{R\rightarrow+\infty}\left[\left(\int\limits_{0}^{R} e^{-x^2}\mathrm{d}x\right)\left(\int\limits_{0}^{R} e^{-y^2}\mathrm{d}y\right)\right]=4\lim_{R\rightarrow+\infty}\left(\int\limits_{0}^{R}\int\limits_{0}^{R} e^{-(x^2+y^2)}\mathrm{d}x\mathrm{d}y\right) \tag{5.7.603}$$

and make a change of variable passing in polar coordinates, therefore we also use the Jacobian in these same coordinates (see section Differential and Integral Calculus page 1524):

$$\begin{aligned}I^2&=4\lim_{R\rightarrow+\infty}\left(\int\int e^{-r^2}r\mathrm{d}r\mathrm{d}\phi\right)=4\lim_{R\rightarrow+\infty}\left(\int\limits_{0}^{\frac{\pi}{2}}\int\limits_{0}^{R} e^{-r^2}r\mathrm{d}r\mathrm{d}\phi\right)\\&=4\frac{\pi}{2}\lim_{R\rightarrow+\infty}\left(\int\limits_{0}^{R} e^{-r^2}r\mathrm{d}r\right)=2\pi\left(-\frac{1}{2}e^{-r^2}\Big|_0^{+\infty}\right)=2\pi\left(0+\frac{1}{2}\right)=\pi\end{aligned} \tag{5.7.604}$$

Therefore:

$$I=\sqrt{\pi} \tag{5.7.605}$$

By extension for $e^{-\frac{x^2}{2}}$ we have:

$$I=\lambda^{-1}=\sqrt{2\pi} \tag{5.7.606}$$

Hence, the reader must keep in mind for further developments that:

$$\boxed{I=\int\limits_{-\infty}^{+\infty} e^{-x^2}\mathrm{d}x=\sqrt{\pi}} \tag{5.7.607}$$

and that:

$$\boxed{I=\int\limits_{-\infty}^{+\infty} e^{-\frac{x^2}{2}}\mathrm{d}x=\sqrt{2\pi}} \tag{5.7.608}$$

■ Q.E.D.

We thus obtain the "standard Normal distribution" denoted as probability density function (with the capital letter F that may unfortunately lead to confusion in the present development with the notation of the cumulative distribution function... we apologize...):

$$F(x)=\frac{1}{\sqrt{2\pi}}e^{-\frac{x^2}{2}} \tag{5.7.609}$$

which can be calculated in Microsoft® Excel® 11.8346 with the function `NORMSDIST( )`. Notice also that is some textbooks that latter relation is denoted by $\phi(x)$.

Remark

Originally Gauss used the term "normal" (in the sense of "orthogonal") referring to the geometric interpretation of a system of linear (normal) equations from which the distribution bearing his name was derived. Pearson in 11920 (holocene calendar) credited himself for first using the term "normal curve" noting that: « *while it avoids an international question of priority [of Gauss vs Laplace], has the disadvantage of leading people to believe that all other distributions are 'abnormal'.*»

For information, a random variable following a Normal centered reduced distribution is by tradition often denoted by the letter Z ("Zentriert" in German meaning "centered" in English) and its realization by a lowercase z.

Returning to non-normalized variables (i.e. non-standardized) by remembering that:

$$x=\frac{k-np}{\sqrt{npq}}=\frac{k-\mu}{\sigma} \tag{5.7.610}$$

We get the "Gauss-Laplace function" (or "Gauss-Laplace law") or also named "Normal distribution" given in the form of probability density in this textbook by:

$$\boxed{P(k,\mu,\sigma)=\mathcal{N}(\mu,\sigma)=\frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(k-\mu)^2}{2\sigma^2}}} \tag{5.7.611}$$

Remark

So in general the reader must keep in mind that when a random variable x follows a $\mathcal{N}(\mu,\sigma)$, then standardizing it by subtracting it's mean (i.e. a "mean normalization") and dividing it by it's own standard deviation, make him follow a Normal centered reduced distribution Z so that its realization will be denoted:

$$z=\frac{x-\mu_x}{\sigma_x} \tag{5.7.612}$$

and named "Z-factor". Using this factor for non-Normal distributions can be a bit tricky. Without checking the Normality of the underlying data with a Kolmogorov-Smirnov, Anderson-Darling, Ryan-Joiner or one of the other many Normality tests (see page 1111) it should be avoided! Also doing a data adjustment like the Johnson transformation can completely change the interpretation of the results and in most cases should also be avoided. So as always in science: don't use any metric blindly without checking how it really works!

The cumulative probability (distribution cumulative function) to have a certain value k is obviously given in this special case by:

$$P(k \leq x) = \Phi(x) = \frac{1}{\sigma\sqrt{2\pi}} \int\limits_{-\infty}^{x} e^{-\frac{(k-\mu)^2}{2\sigma^2}} \mathrm{d}k \tag{5.7.613}$$

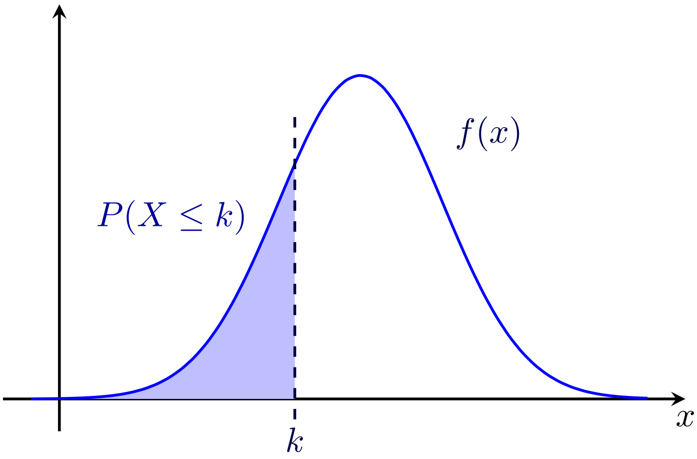

Figure 5.127: **Gaussian distribution cumulated area (author: Izaak Neutelings)**

On the request of a reader let us see how the cumulative function is often presented in textbooks... First remember that the density function of the Normal distribution is given by:

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{5.7.614}$$

Thus, the cumulative distribution function is:

$$\begin{aligned} F_X(x) &= \int\limits_{-\infty}^{x} \mathcal{N}\left(z;\mu,\sigma^2\right) \mathrm{d}z \\ &= \int\limits_{-\infty}^{x} \frac{1}{\sqrt{2\pi}\sigma} \cdot \exp\left[-\frac{1}{2}\left(\frac{z-\mu}{\sigma}\right)^2\right] \mathrm{d}z \\ &= \frac{1}{\sqrt{2\pi}\sigma} \int\limits_{-\infty}^{x} \exp\left[-\left(\frac{z-\mu}{\sqrt{2}\sigma}\right)^2\right] \mathrm{d}z \end{aligned} \tag{5.7.615}$$

Substituting $t=(z-\mu)/(\sqrt{2}\sigma)$, i.e. $z=\sqrt{2}\sigma t+\mu$, this becomes:

$$\begin{aligned}F_X(x)&=\frac{1}{\sqrt{2\pi}\sigma}\int\limits_{(-\infty-\mu)/(\sqrt{2}\sigma)}^{(x-\mu)/(\sqrt{2}\sigma)}\exp\left(-t^2\right)\mathrm{d}(\sqrt{2}\sigma t+\mu)\\&=\frac{\sqrt{2}\sigma}{\sqrt{2\pi}\sigma}\int\limits_{-\infty}^{\frac{x-\mu}{\sqrt{2}\sigma}}\exp\left(-t^2\right)\mathrm{d}t\\&=\frac{1}{\sqrt{\pi}}\int\limits_{-\infty}^{\frac{x-\mu}{\sqrt{2}\sigma}}\exp\left(-t^2\right)\mathrm{d}t\\&=\frac{1}{\sqrt{\pi}}\int\limits_{-\infty}^{0}\exp\left(-t^2\right)\mathrm{d}t+\frac{1}{\sqrt{\pi}}\int_0^{\frac{x-\mu}{\sqrt{2}\sigma}}\exp\left(-t^2\right)\mathrm{d}t\\&=\frac{1}{\sqrt{\pi}}\int\limits_{0}^{\infty}\exp\left(-t^2\right)\mathrm{d}t+\frac{1}{\sqrt{\pi}}\int\limits_{0}^{\frac{x-\mu}{\sqrt{2}\sigma}}\exp\left(-t^2\right)\mathrm{d}t\end{aligned}\tag{5.7.616}$$

We recognize here the Error function (see section Thermodynamics page 3697) defined for reminder by:

$$\mathrm{erf}(x)=\frac{2}{\sqrt{\pi}}\int\limits_0^x\exp\left(-t^2\right)\mathrm{d}t\tag{5.7.617}$$

Hence the last equality can be rewritten:

$$\begin{aligned}F_X(x)&=\frac{1}{2}\lim_{x\to\infty}\mathrm{erf}(x)+\frac{1}{2}\mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\\&=\frac{1}{2}+\frac{1}{2}\mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\\&=\frac{1}{2}\left[1+\mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right]\end{aligned}\tag{5.7.618}$$

Hence the famous relation:

$$F_X(x)=\frac{1}{2}\left[1+\mathrm{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right]\tag{5.7.619}$$

Caution! Because there is no closed formula for the cumulative distribution of the Normal law (and the same occurs for others statistical laws), there are plenty of different numerical implementation of the latter. For example eighteen (!!!) different numerical implementation exist for the Normal law as detailed in the paper [587] (the Zelen and Severo, Hart, Marsaglia, Cody, Dia, Shore methods etc.). That's why you will get the same result in SAS and Microsoft® Excel® at the eighth decimal but the result will be slightly different from Python™ and the GNU Scientific Library that doesn't use the same numerical implementation. None of the returned value is more exact than another one! It would be a nonsense ton claim the opposite! That's why professional scientists and statisticians communicate and validate their results for very important and critical statistics using three different tools/softwares at least!

Here is a plot example of the distribution and cumulative distribution function for the Normal law with the parameters example $(\mu, \sigma) = (0, 1)$ that is therefore the standard centered reduced Normal distribution:

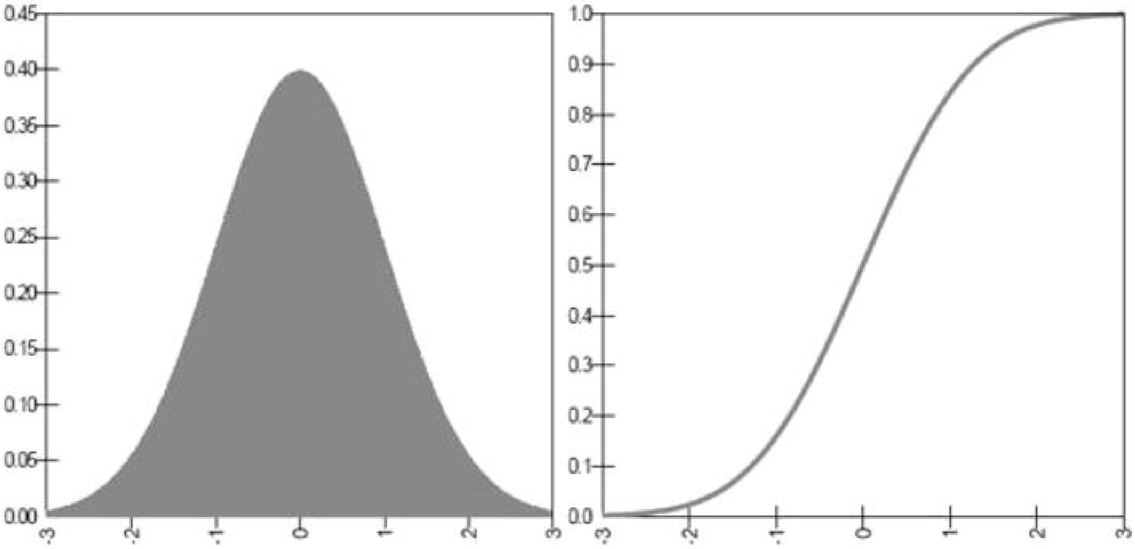

Figure 5.128: **Normal law $\mathcal{N}$ (mass and cumulative distribution function)**

This law governs under very general conditions, and often encountered, in many random phenomena. It is also symmetrical with respect to the mean (this is important to remember!).

We will now show that μ well represents the mean (or average) of x (this is a bit silly but we can still check ...):

$$\text{E}(X)=\int\limits_{-\infty}^{+\infty} xf(x)\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} e^{-\frac{(x-\mu)^2}{2\sigma^2}}\mathrm{d}x \tag{5.7.620}$$

We put:

$$u=\frac{x-\mu}{\sigma} \tag{5.7.621}$$

We then have:

$$\begin{aligned}\mathrm{E}(X)&=\int\limits_{-\infty}^{+\infty}xf(x)\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}(\sigma u+\mu)e^{-\frac{u^2}{2}}\sigma\mathrm{d}u\\&=\sigma\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}\sigma ue^{-\frac{u^2}{2}}\mathrm{d}u+\sigma\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}\mu e^{-\frac{u^2}{2}}\mathrm{d}u\\&=\sigma\frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}ue^{-\frac{u^2}{2}}\mathrm{d}u+\frac{1}{\sqrt{2\pi}}\mu\int\limits_{-\infty}^{+\infty}e^{-\frac{u^2}{2}}\mathrm{d}u\end{aligned}\tag{5.7.622}$$

Let us now calculate the first integral:

$$J=\int\limits_{-\infty}^{+\infty}ue^{-\frac{u^2}{2}}\mathrm{d}u=-e^{-\frac{u^2}{2}}\Big|_{-\infty}^{+\infty}=e^{-\frac{u^2}{2}}\Big|_{+\infty}^{-\infty}=0-0=0\tag{5.7.623}$$

So we finally get:

$$\mathrm{E}(X)=\frac{1}{\sqrt{2\pi}}\mu\int\limits_{-\infty}^{+\infty}e^{-\frac{u^2}{2}}\mathrm{d}u=\frac{1}{\sqrt{2\pi}}\mu\sqrt{2\pi}=\mu\tag{5.7.624}$$

Remarks

R1. The reader might find confusing at first that the parameter of a function is one of the results that we seek of this same function (as for the Poisson distribution). What bothers is to put in practice such a thing. In fact, everything will be more clear when we will discuss later in this chapter the concepts of "likelihood estimators".

R2. It could be interesting to know for the reader that in practice (finance, quality assurance, etc.) it is common to have to calculate only mean only positive values of the random variable which is then naturally defined as "positive mean" and given by:

$$\mathrm{E}^{+}(X)=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{0}^{+\infty}xe^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}\mathrm{d}x\tag{5.7.625}$$

We will see a practical example of this last relation in the section Economy during our study of the theoretical model of speculation of Louis Bachelier (page 7689).

Also we will prove now (...) that σ is the standard deviation of X (in other words to prove that $\mathrm{V}(X)=\sigma^2$) and for this we recall that we had prove that (Huygens relation):

$$\mathrm{V}(X)=\mathrm{E}(X^2)-\mathrm{E}(X)^2\tag{5.7.626}$$

We already know that at the level of the notations we have:

$$\mathrm{E}(X)=\mu\Rightarrow\mathrm{E}(X)^2=\mu^2\tag{5.7.627}$$

then we first calculate $\mathrm{E}(X^2)$:

$$\mathrm{E}(X^2)=\int x^2 f(x)\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} x^2 e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}\mathrm{d}x \qquad (5.7.628)$$

Let $y=(x-\mu)/\sqrt{2}\sigma$ that therefore leads us to:

$$\begin{aligned}\mathrm{E}(X^2)&=\int x^2 f(x)\mathrm{d}x=\frac{1}{\sigma\sqrt{\pi}}\int\limits_{-\infty}^{+\infty}(y\sqrt{2}\sigma+\mu)^2 e^{-y^2}\mathrm{d}x\\&=\frac{2}{\sigma\sqrt{\pi}}\int\limits_{-\infty}^{+\infty} y^2 e^{-y^2}\mathrm{d}y+2\mu\sigma\sqrt{\frac{2}{\pi}}\int\limits_{-\infty}^{+\infty} y e^{-y^2}\mathrm{d}y+\frac{\mu^2}{\sqrt{\pi}}\int\limits_{-\infty}^{+\infty} e^{-y^2}\mathrm{d}y\end{aligned} \qquad (5.7.629)$$

And we know that (already proved above):

$$\int\limits_{-\infty}^{+\infty} y e^{-y^2}\mathrm{d}y=0 \qquad \int\limits_{-\infty}^{+\infty} e^{-y^2}\mathrm{d}y=\sqrt{\pi} \qquad (5.7.630)$$

It remains to calculate therefore only the first integral. To do this, we proceed by integration by parts (see section Differential and Integral Calculus page 1532):

$$\int\limits_a^b f(t)g'(t)\mathrm{d}t=f(t)g(t)|_a^b-\int\limits_a^b f'(t)g(t)\mathrm{d}t \qquad (5.7.631)$$

leads us to:

$$\int\limits_{-\infty}^{+\infty} y^2 e^{-y^2}\mathrm{d}y=\int\limits_{-\infty}^{+\infty} y\left(ye^{-y^2}\right)\mathrm{d}y=-y\frac{e^{-\frac{y^2}{2}}}{2}\Bigg|_a^b+\int\limits_{-\infty}^{+\infty}\frac{e^{-y^2}}{2}\mathrm{d}y=\frac{\sqrt{\pi}}{2} \qquad (5.7.632)$$

Then we get:

$$\mathrm{E}(X^2)=\frac{2}{\sqrt{\pi}}\sigma^2\frac{\sqrt{\pi}}{2}+2\mu\sigma\sqrt{\frac{2}{\pi}}0+\frac{\mu^2}{\sqrt{\pi}}\sqrt{\pi}=\mu^2+\sigma^2 \qquad (5.7.633)$$

And finally:

$$\mathrm{V}(X)=\mathrm{E}(X^2)-\mathrm{E}(X)^2=(\mu^2+\sigma^2)-\mu^2=\sigma^2 \qquad (5.7.634)$$

An additional signification of the standard deviation of Gauss-Laplace distribution is a measure of the width of the distribution as (this can be checked only with the aid of integration by using numerical methods) for any non-zero mean and standard deviation we have (thanks to John Cannin for the LaTeX figure):

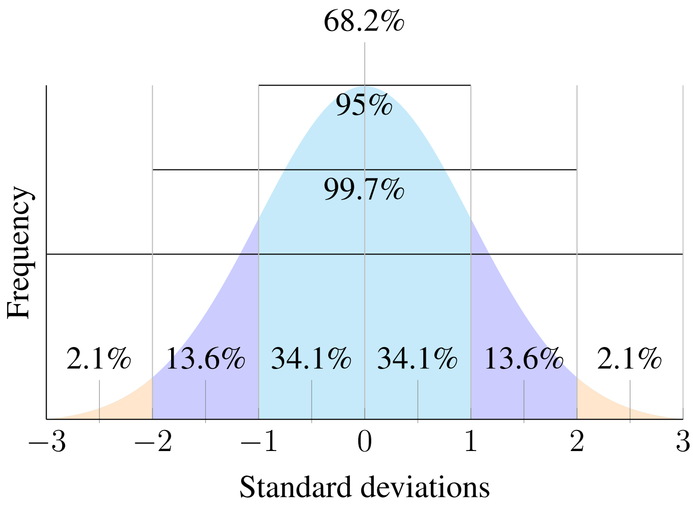

Figure 5.129: **Sigma intervals for the Normal distribution**

The width of the interval has a great importance in the interpretation of uncertainties measurement. The presentation of a result like $\bar{N} \pm \sigma$ has for signification that the average value has about 68.3% chance (probability) to lie between the limits of $\bar{N}-\sigma$ and $\bar{N}+\sigma$ or has approximately 95.4% to lie between the limits of $\bar{N}-2\sigma$ and $\bar{N}+2\sigma$ etc.

Let X be a random variable following a Normal distribution with mean μ and variance σ^2. Then, about 68%, 95% and 99.7% of the values of X will fall within 1, 2 and 3 standard deviations from the mean, respectively:

$$\begin{aligned} P(\mu-1\sigma\leq X\leq \mu+1\sigma)&\cong 68\%\\ P(\mu-2\sigma\leq X\leq \mu+2\sigma)&\cong 95\%\\ P(\mu-3\sigma\leq X\leq \mu+3\sigma)&\cong 99.7\% \end{aligned} \tag{5.7.635}$$

this is often named the "68-95-99.7 rule".

Indeed, the as we have seen just earlier, the cumulative distribution function of a Normally distributed random variable X is:

$$F_X(x)=\frac{1}{2}\left[1+\operatorname{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \tag{5.7.636}$$

where $\operatorname{erf}(x)$ is for recall the error function defined as:

$$\operatorname{erf}(x)=\frac{2}{\sqrt{\pi}}\int\limits_0^x \exp\left(-t^2\right)\mathrm{d}t \tag{5.7.637}$$

which exhibits a point-symmetry property:

$$\operatorname{erf}(-x)=-\operatorname{erf}(x) \tag{5.7.638}$$

Thus, the probability that X falls between $\mu - a\cdot\sigma$ and $\mu + a\cdot\sigma$ is equal to:

$$\begin{aligned}
p(a) &= P(\mu - a\sigma \leq X \leq \mu + a\sigma)\\
&= F_X(\mu + a\sigma) - F_X(\mu - a\sigma)\\
&= \frac{1}{2}\left[1 + \text{erf}\left(\frac{\mu + a\sigma - \mu}{\sqrt{2}\sigma}\right)\right] - \frac{1}{2}\left[1 + \text{erf}\left(\frac{\mu - a\sigma - \mu}{\sqrt{2}\sigma}\right)\right]\\
&= \frac{1}{2}\left[\text{erf}\left(\frac{\mu + a\sigma - \mu}{\sqrt{2}\sigma}\right) - \text{erf}\left(\frac{\mu - a\sigma - \mu}{\sqrt{2}\sigma}\right)\right]\\
&= \frac{1}{2}\left[\text{erf}\left(\frac{a}{\sqrt{2}}\right) - \text{erf}\left(-\frac{a}{\sqrt{2}}\right)\right]\\
&= \frac{1}{2}\left[\text{erf}\left(\frac{a}{\sqrt{2}}\right) + \text{erf}\left(\frac{a}{\sqrt{2}}\right)\right]\\
&= \text{erf}\left(\frac{a}{\sqrt{2}}\right)
\end{aligned} \tag{5.7.639}$$

With that, we can use numerical implementations of the error function to calculate:

$$\begin{aligned}
P(\mu - 1\sigma \leq X \leq \mu + 1\sigma) = p(1) = 68.27\%\\
P(\mu - 2\sigma \leq X \leq \mu + 2\sigma) = p(2) = 95.45\%\\
P(\mu - 3\sigma \leq X \leq \mu + 3\sigma) = p(3) = 99.73\%
\end{aligned} \tag{5.7.640}$$

Remark

This concept is widely used in quality management in industrial business especially with the Six Sigma methodology (see Industrial Engineering page 8674) which requires a mastery of 6 around each side of the mean (!) of the manufacturing (or anything else whose deviation is measured).

Sigma Quality Level	Insured non-defection rate in %	Defection rate in parts per million
1σ	68.26894	317,311
2σ	95.4499	45,500
3σ	99.73002	2,700
4σ	99.99366	63.4
5σ	99.999943	0.57
6σ	99.9999998	0.002

Table 5.41: **Sigma quality level with defection / non-defection rate**

The second column of the table can easily be obtained with Maple™ 4.00b (or also with the spreadsheet software from Microsoft). For example for the first line:

```
>S:=evalf(int(1/sqrt(2*Pi)*exp(-x^2/2),x=-1..1));
```

and the first row of the third column:

```
>(1-S)*1E6;
```

If the Normal distribution was not centered, then we just would write for the second column:

```
>S:=evalf(int(1/sqrt(2*Pi)*exp(-(x-mu)^2/2),x=-1..1));
```

and so on for any deviation and mean we will then obtain exactly the same intervals!!!

Let X be a random variable following a Normal distributions :

$$X \sim \mathcal{N}\left(\mu, \sigma^2\right) \tag{5.7.641}$$

Then, the quantile function of X is:

$$Q_X(p) = \sqrt{2}\sigma \cdot \text{erf}^{-1}(2p-1) + \mu \tag{5.7.642}$$

where $\text{erf}^{-1}(x)$ is the inverse error function.

Indeed, we have proven earlier that the cumulative function of the Normal distribution was:

$$F_X(x) = \frac{1}{2}\left[1 + \text{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \tag{5.7.643}$$

Because the cumulative distribution function (CDF) is strictly monotonically increasing, the quantile function is equal to the inverse of the CDF :

$$Q_X(p) = F_X^{-1}(x) \tag{5.7.644}$$

This can be derived by rearranging the prior-previous relation:

$$\begin{aligned} p &= \frac{1}{2}\left[1 + \text{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \\ 2p-1 &= \text{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right) \\ \text{erf}^{-1}(2p-1) &= \frac{x-\mu}{\sqrt{2}\sigma} \\ x &= \sqrt{2}\sigma \cdot \text{erf}^{-1}(2p-1) + \mu \end{aligned} \tag{5.7.645}$$

Let us now seek the median of the Normal law (obviously by its symmetry that's quite obvious...)! Remember that the cumulative distribution function of the Normal distribution is given by:

$$F_X(x) = \frac{1}{2}\left[1 + \text{erf}\left(\frac{x-\mu}{\sqrt{2}\sigma}\right)\right] \tag{5.7.646}$$

where $\text{erf}(x)$ is the error function. Thus, the inverse cumulative distribution function is:

$$x = \sqrt{2}\sigma \cdot \text{erf}^{-1}(2p-1) + \mu \tag{5.7.647}$$

where $\text{erf}^{-1}(x)$ is the inverse error function. Setting $p = 1/2$, we get:

$$\text{median}(X) = M_e(X) = \sqrt{2}\sigma \cdot \text{erf}^{-1}(0) + \mu = \mu \tag{5.7.648}$$

Following a reader request, let's prove how to obtain the modal value of the Normal law (even if it is trivial given its symmetry and shape...). So Let X be a random variable following a Normal distribution:

$$X \sim \mathcal{N}\left(\mu, \sigma^2\right) \tag{5.7.649}$$

The probability density function of the Normal distribution is for reminder given by:

$$\text{mode}(X) = \underset{x}{\arg\max} f_X(x) \tag{5.7.650}$$

The first derivative of this function is:

$$f'_X(x) = \frac{\mathrm{d}f_X(x)}{\mathrm{d}x} = \frac{1}{\sqrt{2\pi\sigma^3}} \cdot (-x+\mu) \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{5.7.651}$$

We can therefore calculate the root of the first derivative to get the result:

$$\begin{aligned} f'_X(x) = 0 &= \frac{1}{\sqrt{2\pi\sigma^3}} \cdot (-x+\mu) \cdot \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \\ 0 &= -x+\mu \\ x &= \mu \end{aligned} \tag{5.7.652}$$

Let us now derive the skewness of the centered reduced Normal distribution define for recall as:

$$\gamma_1 = \mathrm{E}\left[\left(\frac{X-\mu}{\sigma}\right)^3\right] = \frac{\mathrm{E}[X^3] - 3\mu\sigma^2 - \mu^3}{\sigma^3} \tag{5.7.653}$$

And hence for the Normal centered reduced distribution $\mathcal{N}(0,1)$:

$$\gamma_1 = \frac{\mathrm{E}[X^3] - 3\cdot 0 \cdot 1 - 0^3}{1^3} = \mathrm{E}[X^3] \tag{5.7.654}$$

Let now $Y = X - a$ be a random variable. Now note that due to symmetry of the Normal law Y and $-Y$ have the same distribution. That implies:

$$\mathrm{E}[Y^3] = \mathrm{E}[(-Y)^3] \tag{5.7.655}$$

This implies that the only possible solution is $\mathrm{E}[Y^3] = 0$. Hence for the Normal Law:

$$\gamma_1 = \mathrm{E}[X^3] = 0 \tag{5.7.656}$$

Let us now derive the kurtosis κ_1 and κ_4 for the centered reduced Normal distribution:

$$\mathcal{N}(0,1) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{+\infty} e^{\frac{x^2}{2}} \mathrm{d}x \tag{5.7.657}$$

For this purpose we use the following usual primitive (see section Differential and Integral Calculus page 1534):

$$\int x^n e^{ax} \mathrm{d}x = \frac{x^n e^{ax}}{a} - \frac{n}{a} \int x^{n-1} a^{ax} \mathrm{d}x \tag{5.7.658}$$

Therefore using also the Gauss integral:

$$\begin{aligned}
\mu_4 &= \int\limits_{-\infty}^{+\infty} x^4 f(x)\mathrm{d}x = \frac{1}{\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} x^4 e^{-\frac{x^2}{2}}\mathrm{d}x\\
&= \frac{2}{\sqrt{2\pi}}\int\limits_{0}^{+\infty} x^4 e^{-\frac{x^2}{2}}\mathrm{d}x = \frac{1}{\sqrt{2\pi}}\int\limits_{0}^{+\infty} y^{\frac{3}{2}} e^{-\frac{y}{2}}\mathrm{d}y\\
&= \frac{1}{\sqrt{2\pi}}\left(-2y^{\frac{3}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + 3\int\limits_{0}^{+\infty} y^{\frac{1}{2}} e^{-\frac{y}{2}}\mathrm{d}y\right)\\
&= \frac{1}{\sqrt{2\pi}}\left(-2y^{\frac{3}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + 3\left[-2y^{\frac{1}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + \int\limits_{0}^{+\infty} y^{-\frac{1}{2}} e^{-\frac{y}{2}}\mathrm{d}y\right]\right)\\
&= \frac{1}{\sqrt{2\pi}}\left(-2y^{\frac{3}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + 3\left[-2y^{\frac{1}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + 2\int\limits_{0}^{+\infty} e^{-\frac{x^2}{2}}\mathrm{d}x\right]\right)\\
&= \frac{1}{\sqrt{2\pi}}\left(-2y^{\frac{3}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + 3\left[-2y^{\frac{1}{2}}e^{-\frac{y}{2}}\Bigg|_0^{+\infty} + 2\frac{\sqrt{2\pi}}{2}\right]\right)\\
&= \frac{1}{\sqrt{2\pi}}\left(-2y^{\frac{3}{2}}e^{-\frac{y}{2}} - 6y^{\frac{1}{2}}e^{-\frac{y}{2}}\right)\Bigg|_0^{+\infty} + 3\\
&= 3
\end{aligned} \tag{5.7.659}$$

Therefore, the kurtosis is:

$$\kappa_1 = \frac{\mu_4}{\sigma^4} = \frac{3}{1^4} = 3 \tag{5.7.660}$$

Hence the normalized kurtosis:

$$\kappa_4 = \kappa_1 - 3 = 0 \tag{5.7.661}$$

Now for our study later of diffraction, let us calculate the "full width at half maximum" (FWHM) which is the difference between the two values of the independent variable at which the dependent variable is equal to half of its maximum value. In other words, it is the width of a spectrum curve measured between those points on the y-axis which are half the maximum amplitude.

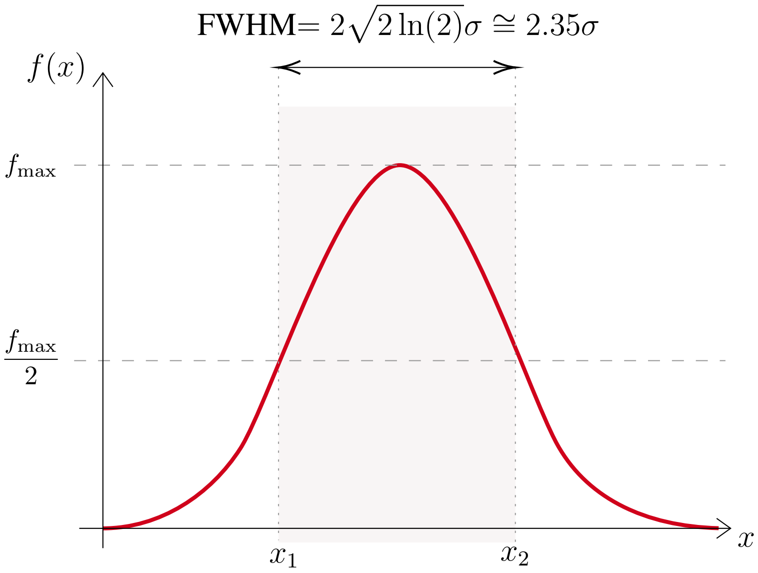

Figure 5.130: **Full width at half maximum (FWHM) illustrated**

FWHM is applied to such phenomena as the duration of pulse waveforms and the spectral width of sources used for optical communications and the resolution capabilities of spectrometers (to calculate crystallite site). The convention of "width" meaning "half maximum" is also widely used in signal processing to define bandwidth as "width of frequency range where less than half the signal's power is attenuated", i.e., the power is at least half the maximum. In signal processing terms, this is at most -3 [dB] of attenuation, named "half-power point" or, more specifically, "half-power bandwidth". When half-power point is applied to antenna beam width, it is named "half-power beam width".

So let X be a random variable following a Normal distribution:

$$X \sim \mathcal{N}\left(\mu,\sigma^2\right) \tag{5.7.662}$$

Then, the full width at half maximum (FWHM) of X is:

$$\text{FWHM}(X) = 2\sqrt{2\ln(2)}\sigma \tag{5.7.663}$$

Indeed, remember that the probability density function of the Normal distribution is as we have seen earlier above:

$$f_X(x) = \frac{1}{\sqrt{2\pi}\sigma}\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{5.7.664}$$

and we have proven just earlier that mode of the Normal distribution is:

$$\text{mode}(X) = \mu \tag{5.7.665}$$

such that:

$$f_{\text{max}} = f_X(\text{mode}(X)) = f_X(\mu) = \frac{1}{\sqrt{2\pi}\sigma} \tag{5.7.666}$$

The FWHM bounds satisfy the equation:

$$f_X\left(x_{\text{FWHM}}\right) = \frac{1}{2}f_{\text{max}} = \frac{1}{2\sqrt{2\pi}\sigma} \tag{5.7.667}$$

Using this cumulative distribution function we can develop this equation as follows:

$$\begin{aligned}
\frac{1}{\sqrt{2\pi}\sigma}\cdot\exp\left[-\frac{1}{2}\left(\frac{x_{\text{FWHM}}-\mu}{\sigma}\right)^2\right] &= \frac{1}{2\sqrt{2\pi}\sigma}\\
\exp\left[-\frac{1}{2}\left(\frac{x_{\text{FWHM}}-\mu}{\sigma}\right)^2\right] &= \frac{1}{2}\\
-\frac{1}{2}\left(\frac{x_{\text{FWHM}}-\mu}{\sigma}\right)^2 &= \ln\frac{1}{2}\\
\left(\frac{x_{\text{FWHM}}-\mu}{\sigma}\right)^2 &= -2\ln\left(\frac{1}{2}\right)\\
\frac{x_{\text{FWHM}}-\mu}{\sigma} &= \pm\sqrt{2\ln(2)}\\
x_{\text{FWHM}}-\mu &= \pm\sqrt{2\ln(2)}\sigma\\
x_{\text{FWHM}} &= \pm\sqrt{2\ln(2)}\sigma+\mu
\end{aligned}\tag{5.7.668}$$

This implies the following two solutions for x_{FWHM}:

$$\begin{aligned}
x_1 &= \mu-\sqrt{2\ln(2)}\sigma\\
x_2 &= \mu+\sqrt{2\ln(2)}\sigma
\end{aligned}\tag{5.7.669}$$

such that the full width at half maximum of X is:

$$\begin{aligned}
\text{FWHM}(X) &= \Delta x = x_2-x_1\\
&= (\mu+\sqrt{2\ln(2)}\sigma)-(\mu-\sqrt{2\ln(2)}\sigma)\\
&= 2\sqrt{2\ln(2)}\sigma
\end{aligned}\tag{5.7.670}$$

The probability density function of the Normal distribution with mean μ and variance σ^2 has two inflection points at $x=\mu-\sigma$ and $x=\mu+\sigma$, i.e. exactly one standard deviation away from the expected value!

To prove this let us remind that the probability density function of the Normal distribution is given by:

$$f_X(x)=\frac{1}{\sqrt{2\pi}\sigma}\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\tag{5.7.671}$$

The first derivative of this function is:

$$f'_X(x)=\frac{\mathrm{d}f_X(x)}{\mathrm{d}x}=\frac{1}{\sqrt{2\pi}\sigma}\cdot\left(-\frac{x-\mu}{\sigma^2}\right)\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\tag{5.7.672}$$

The second derivative is therefore:

$$\begin{aligned}
f''_X(x)=\frac{\mathrm{d}^2f_X(x)}{\mathrm{d}x^2} &= \frac{1}{\sqrt{2\pi}\sigma}\cdot\left(-\frac{1}{\sigma^2}\right)\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]+\frac{1}{\sqrt{2\pi}\sigma}\cdot\left(\frac{x-\mu}{\sigma^2}\right)^2\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]\\
&= \frac{1}{\sqrt{2\pi}\sigma}\cdot\left[\left(\frac{x-\mu}{\sigma^2}\right)^2-\frac{1}{\sigma^2}\right]\cdot\exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]
\end{aligned}\tag{5.7.673}$$

Therefore second derivative is zero, if and only if:

$$\begin{aligned}
0 &= \left[\left(\frac{x-\mu}{\sigma^2}\right)^2-\frac{1}{\sigma^2}\right]\\
0 &= \frac{x^2}{\sigma^4}-\frac{2\mu x}{\sigma^4}+\frac{\mu^2}{\sigma^4}-\frac{1}{\sigma^2}\\
0 &= x^2-2\mu x+\left(\mu^2-\sigma^2\right)\\
x_{1,2} &= -\frac{-2\mu}{2}\pm\sqrt{\left(\frac{-2\mu}{2}\right)^2-\left(\mu^2-\sigma^2\right)}\\
x_{1,2} &= \mu\pm\sqrt{\mu^2-\mu^2+\sigma^2}\\
x_{1,2} &= \mu\pm\sigma
\end{aligned} \tag{5.7.674}$$

hence there are inflection points at $x_{1/2}=\mu\pm\sigma$.

The Gauss-Laplace distribution is also not only a tool for data analysis but also for data generation. Indeed, this distribution is one of the largest used in the world of multinationals that use statistical tools for risk management, project management and simulation where a large number of random variables are to be controlled. The best examples of applications use the softwares Crystal Ball or Palisade @Risk (this last one being my favorite...).

In this context of application (project management), it is also very common to use the sum (task duration) or the product of random variables (customer uncertainty) following Gauss-Laplace distributions. We will see now how to calculate this:

5.7.6.9.1 Sum of two random Normal variables

Let X, Y be two independent random variables. Suppose that X follows the distribution $\mathcal{N}(\mu_1,\sigma_1)$ and that Y follows the distribution $\mathcal{N}(\mu_2,\sigma_2)$. Then the random variable $Z=X+Y$ has a density equal to the convolution product of f_x and f_y (see section Functional Analysis page 2293). That is to say:

$$f_z(s)=\int\limits_{-\infty}^{+\infty} f_X(x)f_Y(y)(s-x)\mathrm{d}x=\frac{1}{2\pi\sigma_1\sigma_2}\int\limits_{-\infty}^{+\infty} e^{-\frac{(x-\mu_1)^2}{2\sigma_1^2}}e^{-\frac{(s-x-\mu_2)^2}{2\sigma_2^2}}\mathrm{d}x \tag{5.7.675}$$

which is equivalent to the joint product (see section Probabilities page 480) of the probabilities of occurrence of the two continuous variables (remember the same kind of calculation in discrete form!).

To simplify the expression, make the change of variable $t=x-\mu_1$ and let us write:

$$a=\mu_1+\mu_2-s \qquad \sigma=\sqrt{\sigma_1^2+\sigma_2^2} \tag{5.7.676}$$

As:

$$\left(s-y-\mu_2^2\right)^2=-\left(-s+y+\mu_2^2\right)^2=\left(-s+y+\mu_2^2\right)^2=(t+a)^2 \tag{5.7.677}$$

we get after a hard to guess rearrangement trick:

$$\begin{aligned}f_z(s)&=\dfrac{1}{2\pi\sigma_1\sigma_2}\int\limits_{-\infty}^{+\infty}e^{-\frac{t^2}{2\sigma_1^2}}e^{-\frac{(t+a)^2}{2\sigma_2^2}}\mathrm{d}t=\dfrac{1}{2\pi\sigma_1\sigma_2}\int\limits_{-\infty}^{+\infty}e^{-\frac{\left(\sigma t+\frac{a\sigma_1^2}{\sigma}\right)^2+\frac{\sigma_1^2a^2\sigma_2^2}{\sigma^2}}{2\sigma_1^2\sigma_2^2}}\mathrm{d}t\\&=\dfrac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{a^2}{2\sigma^2}}\int\limits_{-\infty}^{+\infty}e^{-\frac{\left(\sigma t+\frac{a\sigma_1^2}{\sigma}\right)^2}{2\sigma_1^2\sigma_2^2}}\mathrm{d}t\end{aligned}\tag{5.7.678}$$

We write:

$$u=\dfrac{\sigma t+\dfrac{a\sigma_1^2}{\sigma}}{\sqrt{2}\sigma_1\sigma_2}\Rightarrow\dfrac{\mathrm{d}u}{\mathrm{d}t}=\dfrac{\sigma}{\sqrt{2}\sigma_1\sigma_2}\Rightarrow\mathrm{d}t=\sqrt{2}\sigma_1\sigma_2\dfrac{\mathrm{d}u}{\sigma}\tag{5.7.679}$$

Then:

$$f_z(s)=\dfrac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{a^2}{2\sigma^2}}\int\limits_{-\infty}^{+\infty}e^{-\frac{\left(\sigma t+\frac{a\sigma_1^2}{\sigma}\right)^2}{2\sigma_1^2\sigma_2^2}}\mathrm{d}t=\dfrac{1}{\sqrt{2}\pi\sigma}e^{-\frac{a^2}{2\sigma^2}}\int\limits_{-\infty}^{+\infty}e^{-u^2}\mathrm{d}u\tag{5.7.680}$$

Knowing that (already proved earlier above!):

$$\int\limits_{-\infty}^{+\infty}e^{-u^2}\mathrm{d}u=\sqrt{\pi}\tag{5.7.681}$$

and:

$$a^2=(-s+\mu_1+\mu_2)^2=(s-\mu_1-\mu_2)^2\tag{5.7.682}$$

our relation becomes:

$$\boxed{f_z(s)=\dfrac{1}{\sigma\sqrt{2}\sqrt{\pi}}e^{-\frac{(s-\mu_1-\mu_2)^2}{2\sigma^2}}}\tag{5.7.683}$$

We recognize the expression of the Gauss-Laplace distribution (Normal law) of mean $\mu_1+\mu_2$ and standard deviation $\sigma=\sqrt{\sigma_1^2+\sigma_2^2}$.

Therefore, $X+Y$ follows the distribution as written by physicists (both argument have same units):

$$\mathcal{N}\left(\mu_1+\mu_2,\sqrt{\sigma_1^2+\sigma_2^2}\right)\tag{5.7.684}$$

and as noted by most mathematicians and statisticians:

$$\mathcal{N}\left(\mu_1+\mu_2,\sigma_1^2+\sigma_2^2\right)\tag{5.7.685}$$

The fact that the sum of two Normal random variables always give also a Normal distribution is what we name in statistics "stability of the sum" of the Gauss-Laplace distribution (Normal law). We will find such properties for other distribution that will be discussed later.

So as well as for Poisson random variables, any Normal random variable whose parameters are known is verbatim indefinitely divisible into a finite or infinite number of independent Normal variables that are summed as:

$$\mathcal{N}(\mu,\sigma)=\sum_{i=1}^{n}\mathcal{N}\left(\frac{\mu}{n},\frac{\sigma^2}{n}\right) \tag{5.7.686}$$

Remark

The families of stable distribution by the sum is an important field of study in physics, finance and statistics named "Levy alpha-stable distribution". If time permits, I will present the details of this extremely important study in this chapter.

Notice that from what we have derive above, we can conclude that if we have a random variable X that is Normally distributed and we want to keep it's mean but we want to increase it's standard deviation by a constant c, then we just have to add to itself the quantity $c\cdot(X-\mu)/\sigma$.

5.7.6.9.2 Product of two random Normal variables

Let X,Y be two real independent random variables. We denote by f_X and f_Y the corresponding densities and we seek to determine the density of the variable $Z=XY$ (very important case, particularly in engineering).

Let f denote the density function of the pair (X,Y). Since X,Y are independent (see section Probabilities page 480):

$$f(x,y)=f_X(x)f_Y(y) \tag{5.7.687}$$

The distribution function of Z is:

$$F(Z)=P(Z\leq z)=P(XY\leq z)=\iint_D f(x,y)\mathrm{d}x\mathrm{d}y=\iint_D f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y \tag{5.7.688}$$

where $D=\{(x,y)|xy<z\}$.

D can be rewritten as a disjoint union (we do this for anticipating in the future change of variables a division by zero):

$$D=D_1\sqcup D_2\sqcup D_3 \tag{5.7.689}$$

with:

$$\begin{aligned}D_1&=\left\{(x,y)\in\mathbb{R}^2|xy\leq z\wedge x>0\right\}\\D_2&=\left\{(x,y)\in\mathbb{R}^2|xy\leq z\wedge x<0\right\}\\D_3&=\left\{(x,y)\in\mathbb{R}^2|xy\leq z\wedge x=0\right\}\end{aligned} \tag{5.7.690}$$

We have:

$$F(Z)=\iint_{D_1}f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y+\iint_{D_2}f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y+\underbrace{\iint_{D_3}f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y}_{=0} \tag{5.7.691}$$

The last integral is equal to zero because D_3 is of measurement (thickness) zero for the integral along x.

We then perform the following change of variable:

$$x = x \qquad t = xy \tag{5.7.692}$$

The Jacobian of the transformation (see section Differential and Differential Calculus page 1524) is:

$$\left| \begin{bmatrix} 1 & 0 \\ -t/x^2 & 1/x \end{bmatrix} \right| = \frac{1}{|x|} \tag{5.7.693}$$

Thus:

$$F(z) = \int_{-\infty}^{z} \int_{0}^{+\infty} \frac{f_X(x) f_Y(t/x)}{|x|} \mathrm{d}x\mathrm{d}t + \int_{-\infty}^{z} \int_{-\infty}^{0} \frac{f_X(x) f_Y(t/x)}{|x|} \mathrm{d}x\mathrm{d}t = \int_{-\infty}^{z} \int_{-\infty}^{+\infty} \frac{f_X(x) f_Y(t/x)}{|x|} \mathrm{d}x\mathrm{d}t \tag{5.7.694}$$

Let f_Z be the density of the variable Z. By definition:

$$F(Z \leq z) = F(z) = \int_{-\infty}^{z} f_Z(t) \mathrm{d}t \tag{5.7.695}$$

On the other hand:

$$F(z) = \int_{-\infty}^{z} \int_{-\infty}^{+\infty} \frac{f_X(x) f_Y(t/x)}{|x|} \mathrm{d}x\mathrm{d}t \tag{5.7.696}$$

as we have seen. Therefore:

$$\boxed{f_Z(t) = \int_{-\infty}^{+\infty} \frac{f_X(x) f_Y(t/x)}{|x|} \mathrm{d}x} \tag{5.7.697}$$

What is a bit sad is that in the case of a Gauss-Laplace distribution (Normal distribution), this integral can only be easily calculated numerically ... it is then necessary to use Monte Carlo integration type methods (see section Numerical Methods page 6717).

However according to some research done on the Internet, but without certainty, this integral may be calculated and give a new distribution named "Bessel distribution".

5.7.6.9.3 Bivariate Normal Distribution

If two Normal distributed random variables are independent, we know that their joint probability is equal to the product of their probabilities. So we have:

$$P=P_1P_2=\frac{1}{\sqrt{2\pi}\sigma_1}e^{-\frac{(x-\mu_1)^2}{2\sigma_1^2}}\frac{1}{\sqrt{2\pi}\sigma_2}e^{-\frac{(x-\mu_2)^2}{2\sigma_2^2}}=\frac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{(x-\mu_1)^2}{2\sigma_1^2}-\frac{(x-\mu_2)^2}{2\sigma_2^2}} \tag{5.7.698}$$

Now comes an approach that we will often find in the follow developments: to generalize simple algebra models, you have to think in a Linear Algebra way! Therefore we are left with two vectors involving a scalar product:

$$P=P_1P_2=\frac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{(x-\mu_1)^2}{2\sigma_1^2}-\frac{(x-\mu_2)^2}{2\sigma_2^2}}=\frac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{1}{2}\begin{pmatrix}x_1-\mu_1\\x_2-\mu_2\end{pmatrix}^T\begin{pmatrix}\frac{x_1-\mu_1}{2\sigma_1^2}\\\frac{x_2-\mu_2}{2\sigma_1 2^2}\end{pmatrix}} \tag{5.7.699}$$

But we can do even better because for the moment there is no added value to this notation! Effectively a subtle idea is to involve the determinant of a matrix (see section Linear Algebra page 1961) and the inverse of this same matrix in the previous relation:

$$\begin{aligned}P=P_1P_2&=\frac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{1}{2}\begin{pmatrix}x_1-\mu_1\\x_2-\mu_2\end{pmatrix}^T\begin{pmatrix}\frac{x_1-\mu_1}{2\sigma_1^2}\\\dfrac{x_2-\mu_2}{2\sigma_1 2^2}\end{pmatrix}}\\&=\frac{1}{2\pi(\sigma_1^2\sigma_2^2-0\cdot 0)^{1/2}}e^{-\frac{1}{2}\begin{pmatrix}x_1-\mu_1\\x_2-\mu_2\end{pmatrix}^T\begin{bmatrix}\frac{1}{\sigma_1^2}&0\\0&\frac{1}{\sigma_2^2}\end{bmatrix}\begin{pmatrix}x_1-\mu_1\\x_2-\mu_2\end{pmatrix}}\\&=\frac{1}{2\pi\left|\begin{bmatrix}\sigma_1^2&0\\0&\sigma_2^2\end{bmatrix}\right|^{1/2}}e^{-\frac{1}{2}\begin{pmatrix}x_1-\mu_1\\x_2-\mu_2\end{pmatrix}^T\begin{bmatrix}\sigma_1^2&0\\0&\sigma_2^2\end{bmatrix}^{-1}\begin{pmatrix}x_1-\mu_1\\x_2-\mu_2\end{pmatrix}}\end{aligned} \tag{5.7.700}$$

We thus find a particular case of the variance-covariance matrix. In the field of the bivariate Normal distribution is it is customary to write this last relation in the following form:

$$\boxed{f(X_1,X_2)=\mathcal{N}(\vec{\mu},\Sigma)=\frac{1}{2\pi|\Sigma|^{1/2}}e^{-\frac{1}{2}\overrightarrow{(x-\mu)}^T\Sigma^{-1}\overrightarrow{(x-\mu)}}} \tag{5.7.701}$$

If we make a plot of this function we get:

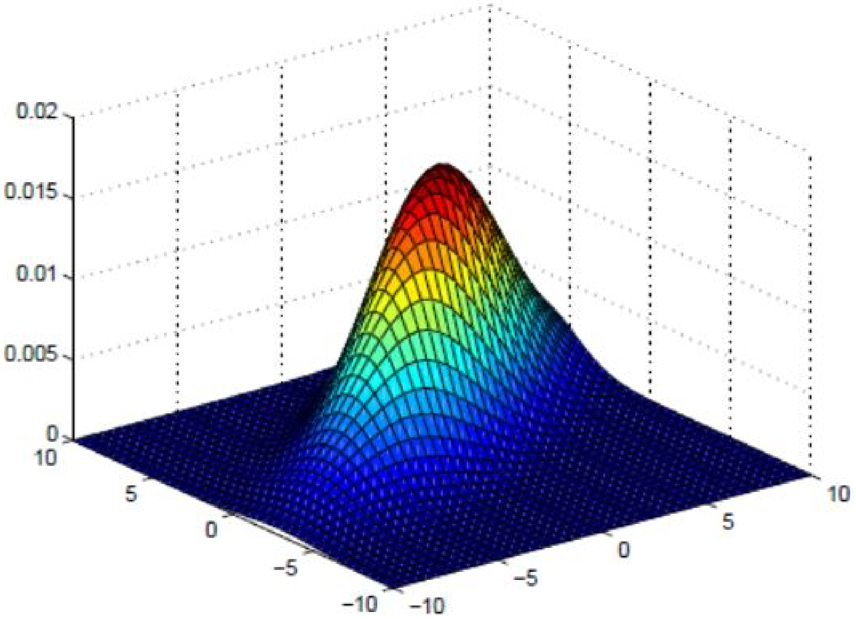

Figure 5.131: **Plot of the bivariate Normal function in MATLAB®**

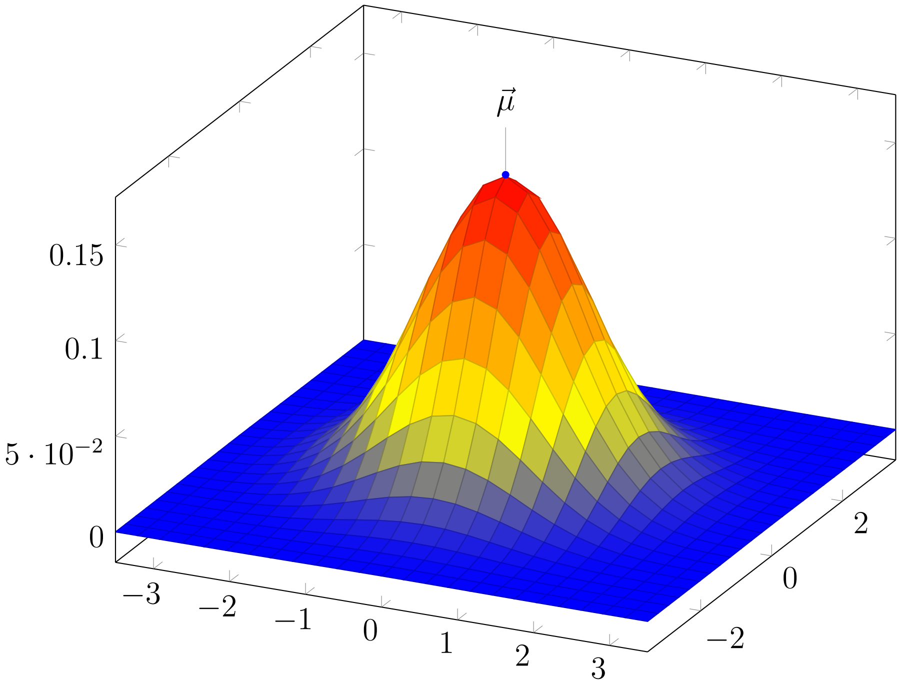
or in high definition with TikZ:



or another one (not with the same values) with corresponding projections:

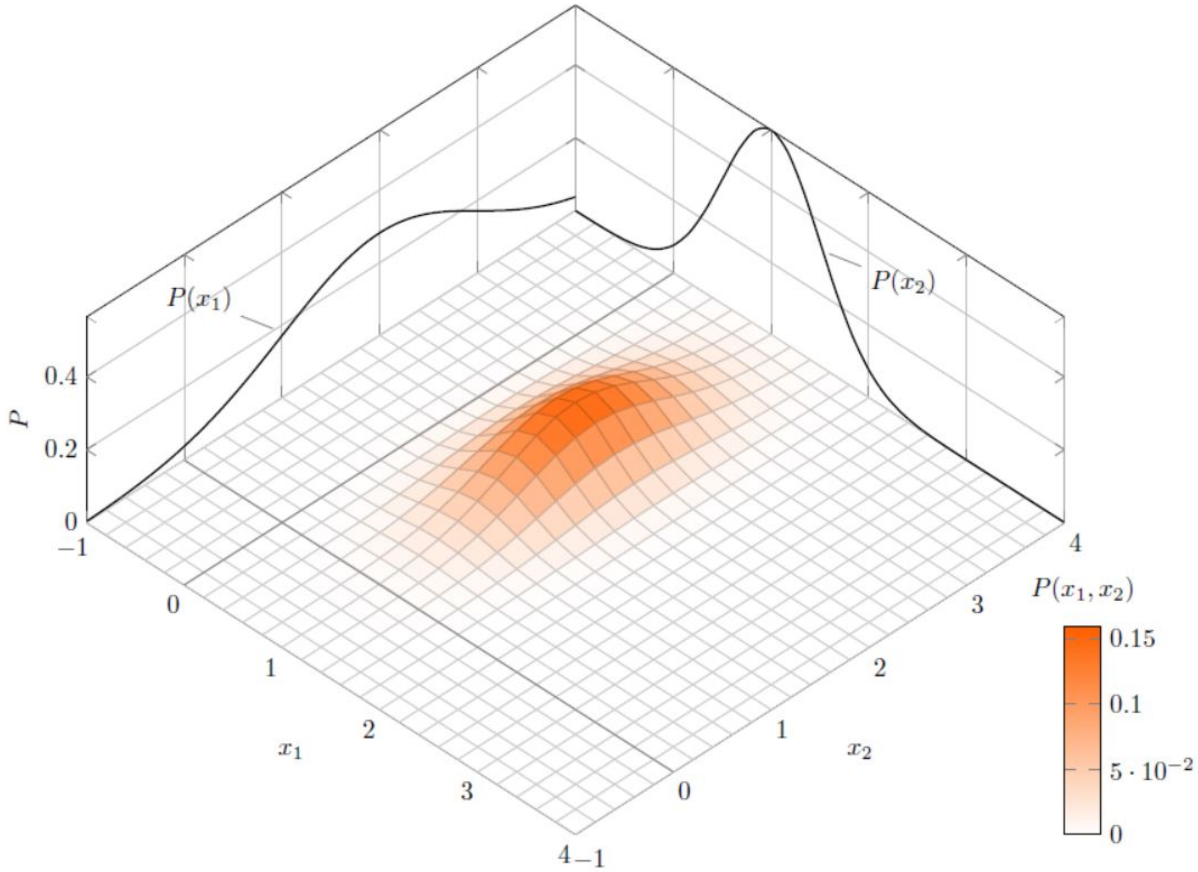


Figure 5.132: Plot of the bivariate Normal function with pgfplots

Now consider the important case in engineering, astronomy and quantum physics by returning to the following notation:

$$P = f(X_1, X_2) = \frac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{(x-\mu_1)^2}{2\sigma_1^2}-\frac{(x-\mu_2)^2}{2\sigma_2^2}} \tag{5.7.702}$$

and by focusing on to the iso-lines such that for any pair of values of the two random variables, we have:

$$\frac{1}{2\pi\sigma_1\sigma_2}e^{-\frac{(x-\mu_1)^2}{2\sigma_1^2}-\frac{(x-\mu_2)^2}{2\sigma_2^2}} = c^{te} \tag{5.7.703}$$

By doing some very basic algebraic manipulations, we get:

$$-\frac{(x-\mu_1)^2}{2\sigma_1^2}-\frac{(x-\mu_2)^2}{2\sigma_2^2} = \ln\left(2\pi\sigma_1\sigma_2 c^{te}\right) \tag{5.7.704}$$

Thus:

$$\frac{(x-\mu_1)^2}{2\sigma_1^2}+\frac{(x-\mu_2)^2}{2\sigma_2^2} = \ln\left(\frac{1}{2\pi\sigma_1\sigma_2 c^{te}}\right) \tag{5.7.705}$$

and we get:

$$\frac{(x-\mu_1)^2}{2\sigma_1^2\ln\left(\frac{1}{2\pi\sigma_1\sigma_2 c^{te}}\right)}+\frac{(x-\mu_2)^2}{2\sigma_2^2\ln\left(\frac{1}{2\pi\sigma_1\sigma_2 c^{te}}\right)} = 1 \tag{5.7.706}$$

We recognize here the analytical equation of an ellipse (see section Analytical Geometric page 2768)!

A plot of iso-lines with $\mu=\begin{pmatrix}3\\2\end{pmatrix}, \Sigma=\begin{bmatrix}25 & 0\\0 & 9\end{bmatrix}$ give us:

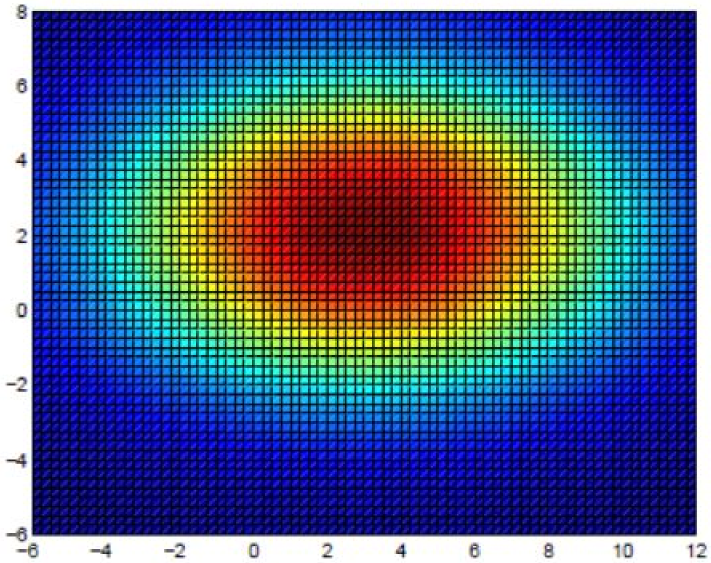

Figure 5.133: Plot of the iso-lines of the bivariate Normal function (non-correlated case)

But now recall that when we got:

$$f(X_1,X_2)=\frac{1}{2\pi|\Sigma|^{1/2}}e^{-\frac{1}{2}\overrightarrow{(x-\mu)}^T\Sigma^{-1}\overrightarrow{(x-\mu)}} \tag{5.7.707}$$

the variance-covariance matrix was zero everywhere except on the diagonal, implying verbatim the independence of the two random variables. We can obviously guess that the generalization is that the variance-covariance matrix is non-zero in the diagonal and then the two random variables are correlated. Consequently, the iso-lines become with values such as $\mu=\begin{pmatrix}3\\2\end{pmatrix}, \Sigma=\begin{bmatrix}10 & 5\\5 & 5\end{bmatrix}$:

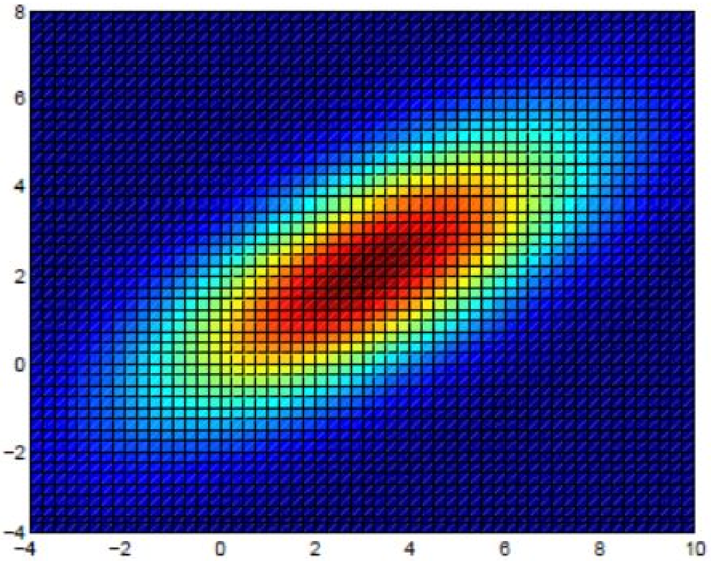

Figure 5.134: Plot of the iso-lines of the bivariate Normal function (correlated case)

So the correlation rotates the axis of the ellipses! Note that we have therefore:

$$\Sigma=\begin{bmatrix}\sigma_{11}^2 & \sigma_{12}\\ \sigma_{21} & \sigma_{22}^2\end{bmatrix}=\begin{bmatrix}\sigma_{11}^2 & \sigma_{12}\\ \sigma_{12} & \sigma_{22}^2\end{bmatrix}\Rightarrow\Sigma^{-1}=\frac{1}{\sigma_{11}^2\sigma_{22}^2-\sigma_{12}^2}\begin{bmatrix}\sigma_{11}^2 & -\sigma_{12}\\ \sigma_{21} & \sigma_{22}^2\end{bmatrix}\tag{5.7.708}$$

and thus verbatim:

$$|\Sigma|=\sigma_{11}^2\sigma_{22}^2-\sigma_{12}^2\tag{5.7.709}$$

Recall that we saw during our study of the correlation coefficient that (well... normally... the R notation for the correlation is used only if the variances are estimated but as it is the most common notation in practice we will still us it...):

$$\sigma_{12}=\text{cov}(X_1,X_2)=\text{c}(X_1,X_2)=R_{X_1,X_2}\sigma_{11}\sigma_{22}\tag{5.7.710}$$

Thus:

$$\Sigma^{-1}=\frac{1}{\sigma_{11}^2\sigma_{22}^2-\sigma_{12}^2}\begin{bmatrix}\sigma_{11}^2 & -\sigma_{12}\\ \sigma_{21} & \sigma_{22}^2\end{bmatrix}=\frac{1}{\sigma_{11}^2\sigma_{22}^2(1-R_{12}^2)}\begin{bmatrix}\sigma_{11}^2 & -\sigma_{12}\\ \sigma_{21} & \sigma_{22}^2\end{bmatrix}\tag{5.7.711}$$

and the exponent of the exponential of the bivariate Normal takes a form that we can find very often in the literature:

$$\begin{aligned}&\begin{pmatrix}x_1-\mu_1\\ x_2-\mu_2\end{pmatrix}^T\left(\frac{1}{\sigma_{11}^2\sigma_{22}^2(1-R_{12}^2)}\begin{bmatrix}\sigma_{11}^2 & -\sigma_{12}\\ \sigma_{21} & \sigma_{22}^2\end{bmatrix}\right)\begin{pmatrix}x_1-\mu_1\\ x_2-\mu_2\end{pmatrix}\\ &=\begin{pmatrix}x_1-\mu_1\\ x_2-\mu_2\end{pmatrix}^T\left(\frac{1}{\sigma_{11}^2\sigma_{22}^2(1-R_{12}^2)}\begin{bmatrix}\sigma_{11}^2 & -R_{12}\sigma_{11}\sigma_{22}\\ -R_{12}\sigma_{11}\sigma_{22} & \sigma_{22}^2\end{bmatrix}\right)\begin{pmatrix}x_1-\mu_1\\ x_2-\mu_2\end{pmatrix}\\ &=\frac{\sigma_{22}^2(x_1-\mu_1)^2+\sigma_{11}^2(x_2-\mu_2)^2-2R_{12}\sigma_{11}\sigma_{22}(x_1-\mu_1)(x_2-\mu_2)}{\sigma_{11}^2\sigma_{22}^2(1-R_{12}^2)}\\ &=\frac{1}{1-R_{12}^2}\left(\left(\frac{x_1-\mu_1}{\sigma_1 1}\right)^2+\left(\frac{x_2-\mu_2}{\sigma_2 2}\right)^2-2R_{12}\left(\frac{x_1-\mu_1}{\sigma_1 1}\right)\left(\frac{x_2-\mu_2}{\sigma_2 2}\right)\right)\end{aligned}\tag{5.7.712}$$

Note that if the random variables are centered reduced, then we have:

$$\Sigma^{-1}=\frac{1}{1-R_{12}^2} \tag{5.7.713}$$

and thus the exponent of the exponential of the bivariate Normal distribution becomes:

$$\Sigma^{-1}=\frac{1}{1-R_{12}^2}\left[x_1^2+x_2^2-2R_{12}x_1x_2\right] \tag{5.7.714}$$

Thus, the density function of the bivariate Normal centered reduced distribution will be written:

$$\begin{aligned}
f(x_1,x_2,R)&=\frac{1}{2\pi(1-R_{12}^2)}e^{-\frac{x_1^2+x_2^2-2R_{12}x_1x_2}{2(1-R_{12}^2)}}\\
&=\frac{1}{\sqrt{2\pi(1-R_{12}^2)}}e^{-x_1^2}\frac{1}{\sqrt{2\pi(1-R_{12}^2)}}e^{-x_2^2}e^{\frac{R_{11}x_1x_2}{1-R_{12}^2}}\\
&=\mathcal{N}(0,1-R_{12}^2)\mathcal{N}(0,1-R_{12}^2)e^{\frac{R_{11}x_1x_2}{1-R_{12}^2}}\\
&=\mathcal{N}(0,1)\mathcal{N}(0,1)\left(1-R_{12}^2\right)^2e^{\frac{R_{11}x_1x_2}{1-R_{12}^2}}
\end{aligned} \tag{5.7.715}$$

Thus, we can see that a bivariate Normal reduced centered distribution function normal can be constructed by the multiplication of two Normal centered and reduced distributions themselves multiplied by a term that depends mainly on the correlation parameter. The latter term includes the nature of the dependence of the two random variables and provides the link between the marginal distributions (both Normal centered and reduced) to obtain the joint bivariate Normal distribution.

If necessary (this can be very useful in practice), here is the Maple™ 4.00b code to plot a bivariate Normal function (taking the last example) even if it is also quite simple to do with a spreadsheet software like Microsoft® Excel®:

```
>f:=(x,y,rho,mu1,mu2,sigma1,sigma2)->(1/(2*Pi*sqrt(sigma1*sigma2*(1-rho^2))))
*exp((-1/(2*(1-rho^2)))*(((x-mu1)/sqrt(sigma1))^2+((y-mu2)/sqrt(sigma2))^2
-2*rho*((x-mu1)/sqrt(sigma1))*((y-mu2)/sqrt(sigma2))));

>plot3d(f(x,y,5/sqrt(10*5),3,2,10,5),x=-4..10,y=-4..9,grid=[40,40]);
```

and for the plot with the iso-lines:

```
>with(plots):
>contourplot(f(x,y,5/sqrt(10*5),3,2,10,5),x=-4..10,y=-4..9,grid=[40,40]);
```

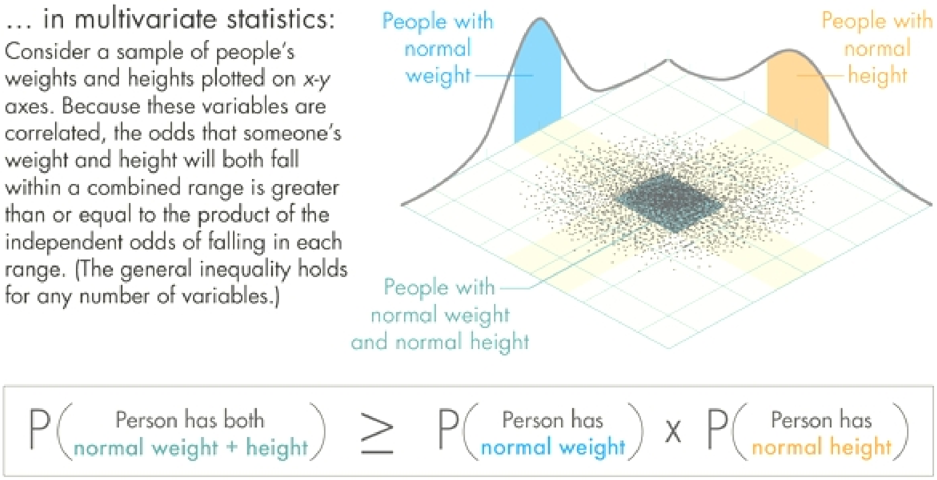
and we can check that it is a probability density function by writing:

```
>int(int(f(x,y,5/sqrt(10*5),3,2,10,5),x=-infinity...+infinity)
,y=-infinity...+infinity);
```

or calculate the cumulative probability between two intervals:

```
>evalf(int(int(f(x,y,5/sqrt(10*5),3,2,10,5),x=-3...+4),y=-5...+2));
```

Notice that it is only in 12014 (holocene calendar) that the "Gaussian correlation conjecture" (also named "Gaussian correlation inequality") was proven by Thomas Royen, a retired German professor of statistics. This conjecture can be summarized with the following figure:



... in multivariate statistics:

Consider a sample of people's weights and heights plotted on x-y axes. Because these variables are correlated, the odds that someone's weight and height will both fall within a combined range is greater than or equal to the product of the independent odds of falling in each range. (The general inequality holds for any number of variables.)

People with normal weight
People with normal height
People with normal weight and normal height
P(Person has both normal weight + height) ≥ P(Person has normal weight) x P(Person has normal height)

We will not provide the proof here as I never needed it for my business or also my customers business but it is quite funny that to know that an inequality that seems quite obvious needed so many years before someone found the proof.

Remark

On July 17, 12014 (holocene calendar), a few years after his retirement, when brushing his teeth, Royen had a flash of insight: how to use the Laplace transform of the multivariate gamma distribution to achieve a relatively simple proof for the Gaussian correlation inequality, a conjecture on the intersection of geometry, probability theory and statistics, formulated after work by Dunnett and Sobel (11955 according to holocene calendar) and the American statistician Olive Jean Dunn (11958 according to holocene calendar) that had remained unsolved since then. He sent a copy of his proof to Donald Richards, an acquainted American mathematician, who worked on a proof of the GCI for 30 years. Richards immediately saw the validity of Royen's proof and subsequently helped him to transform the mathematical formulas into LaTeX (hence the importance to lean LaTeX when we are engineers or scientists!). When Royen contacted other reputed mathematicians, though, they didn't bother to investigate his proof, because Royen was relatively unknown, and these mathematicians therefore estimated the chance that Royen's proof would be false as very high (especially also by sending a Microsoft Word file for peer review your chances to be read are quite low).

5.7.6.9.4 Multivariate Normal distribution

The bivariate Normal distribution is obviously a special case of the multivariate one. We will see now some important properties of the multivariate Normal distribution that we will need later for various statistical tests and methods.

Let us consider the following multivariate Normal distribution $P(\vec{X}) = \mathcal{N}(\vec{\mu}_X, \Sigma_X)$. We want to prove the following multivariate affine transformation that will be useful to us for the study of Factor Analysis later:

$$P(\vec{Y}) = P(A\vec{X} + \vec{b}) = \mathcal{N}(\vec{\mu}_Y, \Sigma_Y) \tag{5.7.716}$$

where:

$$\vec{\mu}_Y = A\vec{\mu}_X + \vec{b} \qquad \Sigma_y = A\Sigma_Y A^T \tag{5.7.717}$$

Proof 5.47.3. Let us see first for the mean:

$$\vec{\mu}_X = \mathrm{E}(A\vec{X} + \vec{b}) = A\mathrm{E}(\vec{X}) + \vec{b} = A\vec{\mu}_X + \vec{b} \tag{5.7.718}$$

and now for the variance-covariance matrix:

$$\begin{aligned}
\Sigma_Y &= \mathrm{E}\left[(\vec{Y} - \vec{\mu}_Y)(\vec{Y} - \vec{\mu}_Y)^T\right] \\
&= \mathrm{E}\left\{\left[(A\vec{X} + \vec{b}) - (A\vec{\mu}_X + \vec{b})\right]\left[(A\vec{X} + \vec{b}) - (A\vec{\mu}_X + \vec{b})\right]^T\right\} \\
&= \mathrm{E}\left[(A\vec{X} - A\vec{\mu}_X)(A\vec{X} - A\vec{\mu}_X)^T\right] \\
&= A\mathrm{E}\left[(\vec{X} - \vec{\mu}_X)(\vec{X} - \vec{\mu}_X)^T\right] \\
&= A\Sigma_X A^T
\end{aligned} \tag{5.7.719}$$

■ Q.E.D.

Notice some special cases:

- If $A = \mathbb{1}$, then:

$$P(\vec{X} + \vec{b}) = \mathcal{N}(\vec{\mu}_X + \vec{b}, \Sigma_X) \tag{5.7.720}$$

- If $\vec{b} = \vec{0}$, then:

$$P(A\vec{X}) = \mathcal{N}(\vec{\mu}_X, A\Sigma_X A^T) \tag{5.7.721}$$

- If $P(\vec{X}) = \mathcal{N}\left([\mu_1, \ldots, \mu_n]^T, \mathrm{diag}[\sigma_1^2, \ldots, \sigma_2^2]\right)$, then:

$$P\left(\sum_{i=1}^{n} x_i\right) = \mathcal{N}\left(\sum_{i}^{n} \mu_i, \sum_{i}^{n} \sigma_i^2\right) \tag{5.7.722}$$

Now let us move to another property of multivariate Normal distribution.

For this, let us recall first that the product of two univariate gaussian probability density functions is given by:

$$\begin{aligned}P(x)P(y)&=\mathcal{N}(\mu_x,\sigma_x)\mathcal{N}(\mu_y,\sigma_y)\\&=\frac{1}{\sqrt{2\pi\sigma_x}}e^{-\frac{(x-\mu_x)^2}{\sigma_x^2}}\frac{1}{\sqrt{2\pi\sigma_y}}e^{-\frac{(y-\mu_y)^2}{\sigma_y^2}}=\frac{1}{2\pi\sigma_x\sigma_y}e^{-\left(\frac{(x-\mu_x)^2}{2}+\frac{(y-\mu_y)^2}{2}\right)}\end{aligned} \tag{5.7.723}$$

Remark

Do not confuse the product of the Normal distributed variables, and the product of their respective probability density functions!!!!

Indeed, the product of the probability density functions of two random variables X and Y will give the joint distribution of the vector-valued random variable (X, Y) in the case that X and Y are independent. Therefore, if X and Y are normally distributed independent random variables, the product of their respective probability density function is bivariate normal with zero correlation (but the result isn't technically speaking a probability density function!).

On the other hand, even in the case that X and Y are independent and identically standard Normal random variables, their product is not itself Normal (it's easy to check in the case where we put $Y = X$ as X^2 cannot be negative, hence it's not Normally distributed!).

Now let us consider for further needs the following multivariate gaussian variable notation:

$$\begin{aligned}P_i(\vec{x})&=\mathcal{N}\left(\vec{x},\vec{\mu}_i,\Sigma_i\right)=\frac{1}{(2\pi)^{n/2}\left|\Sigma_i\right|^{1/2}}\exp\left[-\frac{1}{2}\left(\vec{x}-\vec{\mu}_i\right)^T\Sigma_i^{-1}\left(\vec{x}-\vec{\mu}_i\right)\right]\\&=\frac{1}{(2\pi)^{n/2}\left|\Sigma_i\right|^{1/2}}\exp\left[-\frac{1}{2}\left(\vec{x}^T\Sigma_i^{-1}\vec{x}-2\vec{x}^T\Sigma_i^{-1}\vec{\mu}_i+\vec{\mu}_i\Sigma_i^{-1}\vec{\mu}_i\right)\right]\\&=\exp\left[-\frac{1}{2}\left[n\ln(2\pi)+\ln\left|\Sigma_i\right|+\vec{\mu}_i\Sigma_i^{-1}\vec{\mu}_i\right]\right]\exp\left[-\frac{1}{2}\left(\vec{x}^T\Sigma_i^{-1}\vec{x}-2\vec{x}^T\Sigma_i^{-1}\vec{\mu}_i\right)\right]\\&=\exp\left[-\frac{1}{2}\left[\vec{x}^T\Sigma_i^{-1}\vec{x}-2\vec{x}^T\Sigma_i^{-1}\vec{\mu}_i+c_i\right]\right]\end{aligned} \tag{5.7.724}$$

where:

$$c_i=n\ln(2\pi)+\ln\left|\Sigma_i\right|+\vec{\mu}_i\Sigma_i^{-1}\vec{\mu}_i \tag{5.7.725}$$

Now for the need of our study of Factor Analysis, let us consider a same random variable $\vec{x}$ inject into two multivariate Normal distribution with different mean and variance-covariance matrix:

$$\begin{aligned}P_1(\vec{x})P_2(\vec{x}) &= \mathcal{N}\left(\vec{x},\vec{\mu}_1,\Sigma_1\right)\mathcal{N}\left(\vec{x},\vec{\mu}_2,\Sigma_2\right)\\ &= \exp\left[-\frac{1}{2}\left[\vec{x}^T\Sigma_1^{-1}\vec{x}-2\vec{x}^T\Sigma_1^{-1}\vec{\mu}_1+c_1+\vec{x}^T\Sigma_2^{-1}\vec{x}-2\vec{x}^T\Sigma_2^{-1}\vec{\mu}_2+c_2\right]\right]\\ &= \exp\left[-\frac{1}{2}\left[\vec{x}^T\left(\Sigma_1^{-1}+\Sigma_2^{-1}\right)\vec{x}-2\vec{x}^T\left(\Sigma_1^{-1}\vec{\mu}_1+\Sigma_2^{-1}\vec{\mu}_2\right)+c_1+c_2\right]\right]\\ &= \exp\left[-\frac{1}{2}\left[\vec{x}^T\Sigma^{-1}\vec{x}-2\vec{x}^T\Sigma^{-1}\vec{\mu}+c+(c_1+c_2-c)\right]\right]\\ &= \mathcal{N}(\vec{x},\vec{\mu},\Sigma)\exp\left(c_1+c_2-c\right)\propto\mathcal{N}(\vec{x},\vec{\mu},\Sigma)\end{aligned} \tag{5.7.726}$$

Here we have defined:

$$\begin{aligned}c &= n\ln(2\pi)+|\Sigma|+\vec{\mu}^T\Sigma^{-1}\vec{\mu}\\ \Sigma &= \left(\Sigma_1^{-1}+\Sigma_2^{-1}\right)^{-1}\end{aligned} \tag{5.7.727}$$

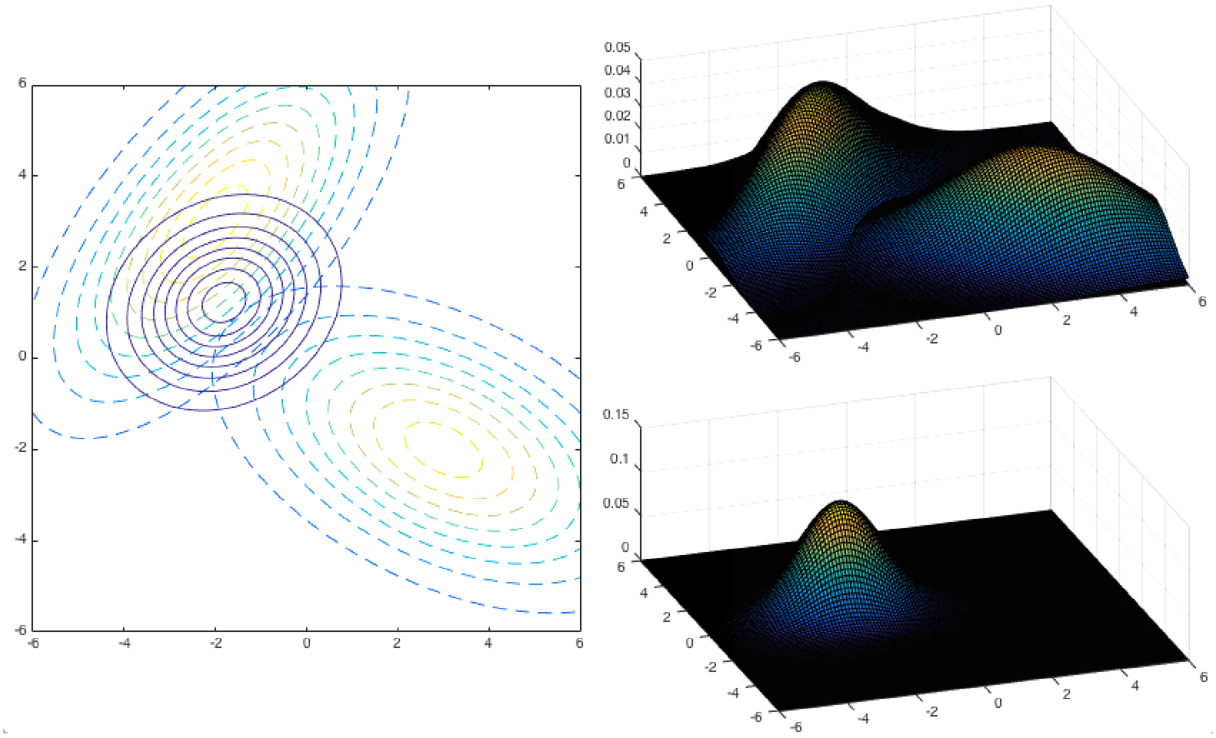
and:

$$\Sigma^{-1}\vec{\mu}=\Sigma_1^{-1}\vec{\mu}_1+\Sigma_2^{-1}\vec{\mu}_2 \tag{5.7.728}$$

i.e.:

$$\vec{\mu}=\Sigma\left(\Sigma_1^{-1}\vec{\mu}_1+\Sigma_2^{-1}\vec{\mu}_2\right)=\left(\Sigma_1^{-1}+\Sigma_2^{-1}\right)^{-1}\left(\Sigma_1^{-1}\vec{\mu}_1+\Sigma_2^{-1}\vec{\mu}_2\right) \tag{5.7.729}$$

We see then that the product of two multivariate gaussians with same random vector is also a scaled Gaussian:



5.7.6.9.4.1 Marginal and conditional distributions of multivariate Normal distributions

For our study later of Factor Analysis we will also need what follows!

A random vector $\vec{x}=[\vec{x}_1^T,\vec{x}_2^T]^T$ with a Normal distribution $\mathcal{N}(\vec{x},\vec{\mu},\Sigma)$ can be partitioned into two subvectors $\vec{x}_1$ and $\vec{x}_2$:

$$P\left(\left[\begin{array}{c}\vec{x}_1\\ \vec{x}_2\end{array}\right]\right)=P(\vec{x})=\mathcal{N}(\vec{x},\vec{\mu},\Sigma)=\mathcal{N}\left(\left[\begin{array}{c}\vec{x}_1\\ \vec{x}_2\end{array}\right],\left[\begin{array}{c}\vec{\mu}_1\\ \vec{\mu}_2\end{array}\right],\left[\begin{array}{cc}\Sigma_{11} & \Sigma_{12}\\ \Sigma_{21} & \Sigma_{22}\end{array}\right]\right) \tag{5.7.730}$$

where:

$$\Sigma_{ij}=\Sigma_{ji}^T,\Sigma_{ii}=\Sigma_{ii}^T \qquad i,j=1,2,i\neq j \tag{5.7.731}$$

Given this Normal joint distribution of $\vec{x}_1$ and $\vec{x}_2$, we can find the Normal conditional distribution of $\vec{x}_i$ given $\vec{x}_j$:

$$P\left(\vec{x}_i|\vec{x}_j\right)=\mathcal{N}\left(\vec{x}_i,\vec{\mu}_{i|j},\Sigma_{i|j}\right) \tag{5.7.732}$$

in terms of the mean vector and the covariance matrix:

$$\begin{cases}\vec{\mu}_{i|j}=\vec{\mu}_i+\Sigma_{ij}\Sigma_{jj}^{-1}\left(\vec{x}_j-\vec{m}_j\right)\\ \Sigma_{i|j}=\Sigma_{ii}-\Sigma_{ij}\Sigma_{jj}^{-1}\Sigma_{ji}\end{cases} \tag{5.7.733}$$

Proof 5.47.4. The joint distribution of $\vec{x}$ is defined as:

$$\begin{aligned}P(\vec{x})=P\left(\vec{x}_1,\vec{x}_2\right)&=\dfrac{1}{(2\pi)^{n/2}|\Sigma|^{1/2}}\exp\left[-\dfrac{1}{2}(\vec{x}-\vec{\mu})^T\Sigma^{-1}(\vec{x}-\vec{\mu})\right]\\ &=\dfrac{1}{(2\pi)^{n/2}|\Sigma|^{1/2}}\exp\left[-\dfrac{1}{2}Q\left(\vec{x}_1,\vec{x}_2\right)\right]\end{aligned} \tag{5.7.734}$$

Here we have defined:

$$\begin{aligned}Q\left(\vec{x}_1,\vec{x}_2\right)&=(\vec{x}-\vec{\mu})^T\Sigma^{-1}(\vec{x}-\vec{\mu})\\ &=\left[\left(\vec{x}_1-\vec{\mu}_1\right)^T,\left(\vec{x}-\vec{\mu}_2\right)^T\right]\left[\begin{array}{cc}\Sigma^{11} & \Sigma^{12}\\ \Sigma^{21} & \Sigma^{12}\end{array}\right]\left[\begin{array}{c}\vec{x}_1-\vec{\mu}_1\\ \vec{x}_2-\vec{\mu}_2\end{array}\right]\\ &=\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma^{11}\left(\vec{x}_1-\vec{m}_1\right)+2\left(\vec{x}_1-\vec{m}_1\right)^T\Sigma^{12}\left(\vec{x}_2-\vec{m}_2\right)+\left(\vec{x}_2-\vec{m}_2\right)^T\Sigma^{22}\left(\vec{x}_2-\vec{m}_2\right)\end{aligned} \tag{5.7.735}$$

where we put:

$$\Sigma^{-1}=\left[\begin{array}{cc}\Sigma_{11} & \Sigma_{12}\\ \Sigma_{21} & \Sigma_{22}\end{array}\right]^{-1}=\left[\begin{array}{cc}\Sigma^{11} & \Sigma^{12}\\ \Sigma^{21} & \Sigma^{22}\end{array}\right] \tag{5.7.736}$$

According to the property of the inverse of a partitioned symmetric matrix (see section Linear Algebra page 1989), we have:

$$\begin{aligned}\Sigma^{11}&=\left(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}\right)^{-1}=\Sigma_{11}^{-1}+\Sigma_{11}^{-1}\Sigma_{12}\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\Sigma_{21}\Sigma_{11}^{-1}\\ \Sigma^{22}&=\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}=\Sigma_{22}^{-1}+\Sigma_{22}^{-1}\Sigma_{21}\left(\Sigma_{11}-\Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}\right)^{-1}\Sigma_{12}\Sigma_{22}^{-1}\\ \Sigma^{12}&=-\Sigma_{11}^{-1}\Sigma_{12}\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}=\left(\Sigma^{21}\right)^T\end{aligned} \tag{5.7.737}$$

Substituting the second expression for Σ^{11}, the first expression for Σ^{22}, and Σ^{12} into $Q(\vec{x}_1,\vec{x}_2)$ we get:

$$\begin{aligned}
Q\left(\vec{x}_1,\vec{x}_2\right) = {} & \left(\vec{x}_1-\vec{\mu}_1\right)^T\left[\Sigma_{11}^{-1}+\Sigma_{11}^{-1}\Sigma_{12}\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\Sigma_{21}\Sigma_{11}^{-1}\right]\left(\vec{x}_1-\vec{\mu}_1\right)\\
& -2\left(\vec{x}_1-\vec{\mu}_1\right)^T\left[\Sigma_{11}^{-1}\Sigma_{12}\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\right]\left(\vec{x}_2-\vec{\mu}_2\right)\\
& +\left(\vec{x}_2-\vec{\mu}_2\right)^T\left[\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\right]\left(\vec{x}_2-\vec{\mu}_2\right)\\
& =\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\\
& +\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma_{11}^{-1}\Sigma_{12}\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\Sigma_{21}\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\\
& -2\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma_{11}^{-1}\Sigma_{12}\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\left(\vec{x}_2-\vec{\mu}_2\right)\\
& +\left(\vec{x}_2-\vec{\mu}_2\right)^T\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\left(\vec{x}_2-\vec{\mu}_2\right)\\
& =\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\\
& +\left[\left(\vec{x}_2-\vec{\mu}_2\right)-\Sigma_{21}\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\right]^T\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\left[\left(\vec{x}_2-\vec{\mu}_2\right)-\Sigma_{21}\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\right]
\end{aligned}\tag{5.7.738}$$

The last equal sign is due to the following equations for any vectors $\vec{u}$ and $\vec{v}$ and a symmetric matrix $A=A^T$:

$$\begin{aligned}
\vec{u}^TA\vec{u}-2\vec{u}^TA\vec{v}+\vec{v}^TA\vec{v} & =\vec{u}^TA\vec{u}-\vec{u}^TA\vec{v}-\vec{u}^TA\vec{v}+\vec{v}^TA\vec{v}\\
& =\vec{u}^TA(\vec{u}-\vec{v})-(\vec{u}-\vec{v})^TA\vec{v}=\vec{u}^TA(\vec{u}-\vec{v})-\vec{v}^TA(\vec{u}-\vec{v})\\
& =(\vec{u}-\vec{v})^TA(\vec{u}-\vec{v})=(\vec{v}-\vec{u})^TA(\vec{v}-\vec{u})
\end{aligned}\tag{5.7.739}$$

To simplify the notations, let us now put:

$$\left\{\begin{array}{l}
\vec{b}=\vec{\mu}_2+\Sigma_{21}\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\\
A=\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}
\end{array}\right.\tag{5.7.740}$$

and also:

$$\left\{\begin{aligned}
Q_1\left(\vec{x}_1\right) & =\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\\
Q_2\left(\vec{x}_1,\vec{x}_2\right) & =\left[\left(\vec{x}_2-\vec{\mu}_2\right)-\Sigma_{21}\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\right]^T\left(\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right)^{-1}\left[\left(\vec{x}_2-\vec{\mu}_2\right)-\Sigma_{21}\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\right]\\
& =\left(\vec{x}_2-\vec{b}\right)^TA^{-1}\left(\vec{x}_2-\vec{b}\right)
\end{aligned}\right.\tag{5.7.741}$$

Then the expression above for $Q(\vec{x}_1,\vec{x}_2)$ can be written as:

$$Q\left(\vec{x}_1,\vec{x}_2\right)=Q_1\left(\vec{x}_1\right)+Q_2\left(\vec{x}_1,\vec{x}_2\right)\tag{5.7.742}$$

and the joint distribution can be written as:

$$\begin{aligned}
P(\vec{x}) & =P\left(\vec{x}_1,\vec{x}_2\right)=\frac{1}{(2\pi)^{n/2}|\Sigma|^{1/2}}\exp\left[-\frac{1}{2}Q\left(\vec{x}_1,\vec{x}_2\right)\right]\\
& =\frac{1}{(2\pi)^{n/2}\left|\Sigma_{11}\right|^{1/2}\left|\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\right|^{1/2}}\exp\left[-\frac{1}{2}Q_1\left(\vec{x}_1\right)\right]\exp\left[-\frac{1}{2}Q_2\left(\vec{x}_1,\vec{x}_2\right)\right]\\
& =\frac{1}{(2\pi)^{p/2}\left|\Sigma_{11}\right|^{1/2}}\exp\left[-\frac{1}{2}\left(\vec{x}_1-\vec{\mu}_1\right)^T\Sigma_{11}^{-1}\left(\vec{x}_1-\vec{\mu}_1\right)\right]\frac{1}{(2\pi)^{q/2}|A|^{1/2}}\exp\left[-\frac{1}{2}\left(\vec{x}_2-\vec{b}\right)^TA^{-1}\left(\vec{x}_2-\vec{b}\right)\right]\\
& =\mathcal{N}\left(\vec{x}_1,\vec{\mu}_1,\Sigma_{11}\right)\mathcal{N}\left(\vec{x}_2,\vec{b},A\right)
\end{aligned}\tag{5.7.743}$$

where we have used the expression of the determinant of a partitioned matrix (see section Linear Algebra page 1990):

$$|\Sigma|=|\Sigma_{11}||\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}| \tag{5.7.744}$$

The marginal distribution of $\vec{x}_1$ is then:

$$\begin{aligned}P_1(\vec{x}_1)&=\int P(\vec{x}_1,\vec{x}_2)\mathrm{d}x_2=\mathcal{N}(\vec{x}_1,\vec{\mu}_1,\Sigma_{11})\int\mathcal{N}(\vec{x}_2,\vec{b},A)\mathrm{d}x_2=\mathcal{N}(\vec{x}_1,\vec{\mu}_1,\Sigma_{11})\cdot 1\\&=\mathcal{N}(\vec{x}_1,\vec{\mu}_1,\Sigma_{11})=\frac{1}{(2\pi)^{p/2}|\Sigma_{11}|^{1/2}}\exp\left[-\frac{1}{2}(\vec{x}_1-\vec{\mu}_1)^T\Sigma_{11}^{-1}(\vec{x}_1-\vec{\mu}_1)\right]\end{aligned} \tag{5.7.745}$$

and the conditional distribution of $\vec{x}_2$ given $\vec{x}_1$ is then:

$$P_{2|1}=\frac{P(\vec{x}_1,\vec{x}_2)}{P_1(\vec{x}_1)}=\mathcal{N}(\vec{x}_2,\vec{b},A)=\frac{1}{(2\pi)^{q/2}|A|^{1/2}}\exp\left[-\frac{1}{2}\left(\vec{x}_2-\vec{b}\right)^T A^{-1}\left(\vec{x}_2-\vec{b}\right)\right] \tag{5.7.746}$$

with for recall:

$$\begin{cases}\vec{b}=\vec{\mu}_{2|1}=\vec{\mu}_2+\Sigma_{21}\Sigma_{11}^{-1}(\vec{x}_1-\vec{\mu}_1)\\ A=\Sigma_{2|1}=\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}\end{cases} \tag{5.7.747}$$

■ Q.E.D.

Then we can deduce two famous results for the special bivariate case (using $\sigma_{12}=\text{cov}(X_1,X_2)=R_{X_1,X_2}\sigma_{11}\sigma_{22}$), i.e. (with the traditional notation in the field of statistics):

$$\begin{cases}\mathrm{E}(Y|X)=\vec{\mu}_{2|1}=\vec{\mu}_2+\Sigma_{21}\Sigma_{11}^{-1}(\vec{x}_1-\vec{\mu}_1)=\mu_Y+\rho\dfrac{\sigma_Y}{\sigma_X}(x-\mu_X)\\ \mathrm{V}(Y|X)=\Sigma_{2|1}=\Sigma_{22}-\Sigma_{21}\Sigma_{11}^{-1}\Sigma_{12}=\sigma_Y^2-\sigma_Y^2\rho^2=\sigma_Y^2(1-\rho^2)\end{cases} \tag{5.7.748}$$

5.7.6.9.5 Normal Reduced Centered Distribution

The Gauss-Laplace distribution is not tabulated as we must then have so many numerical tables as possible values for the mean μ and standard deviation σ (which are the parameters of the function as we have seen it).

Therefore, by a change of variable, the Normal distribution becomes the Normal reduced centered distribution more often named the "standard Normal distribution" where:

1. "Centered" refers to subtracting the mean μ to the measures (thus the distribution function is symmetric to the vertical axis).
2. "Reduced" refers to the division by the standard deviation σ (thus the distribution function has a unit variance).

By this change of variable, the variable k is replaced by the reduced centered random variable:

$$k^{*}=\frac{k-\mu}{\sigma} \tag{5.7.749}$$

If the variable k has for mean μ and standard deviation σ then the variable k^{*} has a mean of 0 and standard deviation of 1 (this last variable is usually denoted by the letter Z).

Thus the relation:

$$P(k,\mu,\sigma)=\frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(k-\mu)^2}{2\sigma^2}} \tag{5.7.750}$$

is therefore written (trivially) more simply:

$$\boxed{P(k^{*},0,1)=\mathcal{N}(0,1)=\frac{1}{\sqrt{2\pi}}e^{-\frac{k^{*2}}{2}}} \tag{5.7.751}$$

which is just the explicit expression of the reduced centered Normal distribution ("standard Normal") often denoted $\mathcal{N}(0,1)$ which we will find very often in the sections of physics, finance, quantitative management and engineering!

The derivation of the inverse of the standard normal PDF is simple (it is useful to know it as not implemented by default in all statistical softwares):

$$\begin{aligned}
y&=\frac{1}{\sqrt{2\pi}}e^{\frac{-1}{2}x^2}\\
\ln(y)&=\log\left(\frac{1}{\sqrt{2\pi}}\right)-\frac{1}{2}x^2\\
x^2&=-2\left(\ln(y)-\log\left(\frac{1}{\sqrt{2\pi}}\right)\right)\\
x&=\sqrt{-2\ln(y\sqrt{2\pi})}
\end{aligned} \tag{5.7.752}$$

Remark

Calculate the integral of the previous relation for an interval can not be done accurately formally speaking. One possible and simple idea is then to express the exponential in a Taylor series and then be integrated term by term of the series (making sure to take enough terms for convergence!).

5.7.6.9.6 Henry's Line

Often in business it is the Gauss-Laplace (Normal) distribution that is analysed but common and easily accessible software like Microsoft® Excel® are unable to verify that the measured data follow a Normal distribution when we do the frequency analysis (there are no default integrated tool allowing users to check this assumption) and we do not have the original ungrouped data.

The trick then is then to use the reduced centered variable that is build as we have seen above with the following relation:

$$k^* = \frac{k-\mu}{\sigma} \tag{5.7.753}$$

The idea of the Henry's Line is then to use the linear relation between k and k^* given by the equation of the line:

$$k^* = f(k) = \frac{k}{\sigma} - \frac{\mu}{\sigma} \tag{5.7.754}$$

and which can be plotted to determine the mean and the standard deviation of the Normal distribution.

✍**Example:**

Suppose we have the following frequencies analysis of $10,000$ receipts in a supermarket:

Price of receipts	**Number of receipts**	**Cumulated number of receipts**	**Relative frequencies of receipts**
$[0,50[$	668	668	0.068
$[50,100[$	919	$1,587$	0.1587
$[100,150[$	$1,498$	$3,085$	0.3085
$[150,200[$	$1,915$	$5,000$	0.5000
$[200,250[$	$1,915$	$6,915$	0.6915
$[250,300[$	$1,498$	$8,413$	0.8413
$[300,350[$	919	$9,332$	0.9332
$[350,400[$	440	$9,772$	0.9772
$[400$ and $+$	228	$10,000$	1

Table 5.42: **Supermarket receipt amount distribution**

If we now plot this in Microsoft® Excel® 11.8346 we get:

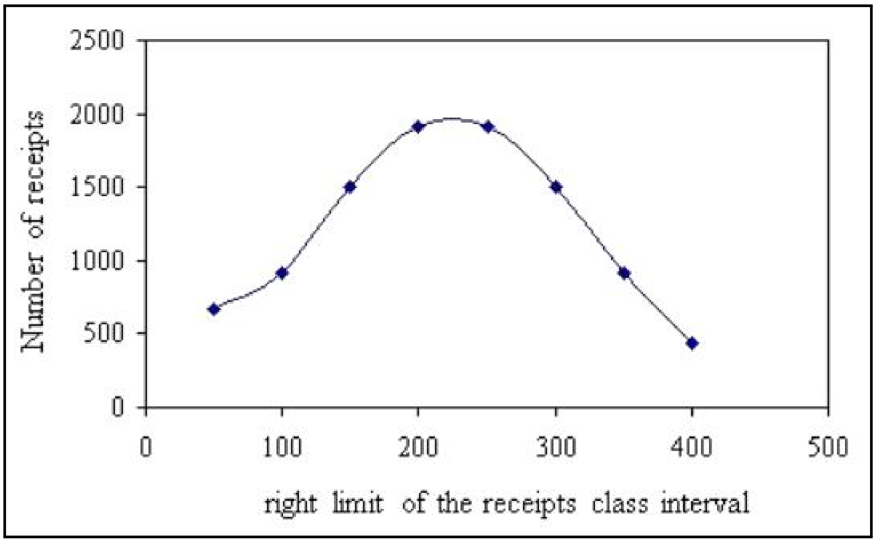


Figure 5.135: **Distribution of receipts amount**

What looks terribly like a Normal distribution, thus the authorization, without too much risk to use in this example the technique of Henry's line.

But what can we do now? Well... now that we know the cumulative frequency, it remains for us to calculate each k^* using numerical tables or the `NORMSINV( )` function of Microsoft® Excel® 11.8346 (remember that formal integration of the Gaussian function is not easy...).

This will give us the values of the standard Normal distribution $\mathcal{N}(0,1)$ of these respective cumulative frequencies (cumulative distribution function). So we get (we leave to the reader to take its statistic table or open its favorite software...):

Upper limit of the interval	**Cumulated relative frequencies**	**Correspondence for k^* of $\mathcal{N}(0,1)$**
50	0.068	-1.5
100	0.1587	-1
150	0.3085	-0.5
200	0.5000	0
250	0.6915	0.5
300	0.8413	1
350	0.9332	1.5
400	0.9772	2
-	1	-

Table 5.43: **Cumulative relative frequencies to the Henry's line**

Note that in the type of table above, in Microsoft® Excel®, the null and unit cumulative frequencies will generated some errors. You should then play a little bit...
As we specified earlier, we have under discrete form:

$$k^*=f(k_i)=\frac{k_i}{\sigma}-\frac{\mu}{\sigma} \quad (5.7.755)$$

So graphically in Microsoft® Excel® 11.8346 we can thanks to our table plot the following chart (obviously we could do strictly a linear regression in the rules of art as seen in the section of Numerical Methods with confidence, prediction intervals and other stuffs...):

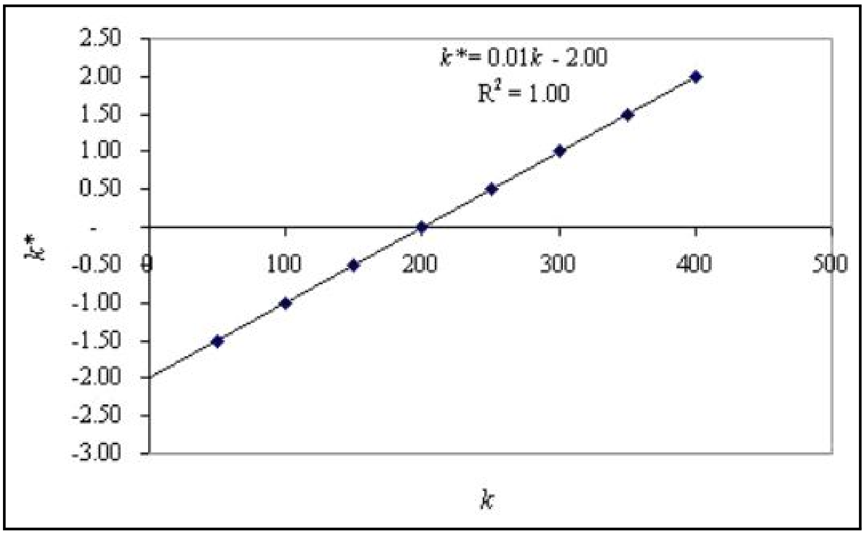

Figure 5.136: **Linearized form of the distribution**

So thanks to the linear regression given by Microsoft® Excel® 11.8346 (or calculated by you using the techniques of linear regressions seen in the section of Numerical Methods page 6316). It comes:

$$k^* = f(k) = \frac{k}{\sigma} - \frac{\mu}{\sigma} = 0.01k - 2 \qquad (5.7.756)$$

we immediately deduce that:

$$\sigma = 100 \quad \mu = 200 \qquad (5.7.757)$$

This is thus a particular technique for a particular distribution! Similar techniques more or less simple (or complicated depending on the case...) exist for others distributions.

See now another approximate approach to solve this problem. Let's take again our table for this example:

Price of receipts	Upper limit of the interval	Center	Relative cumulative frequencies in %
$[0, 50[$	50	25	6.8
$[50, 100[$	100	75	15.87
$[100, 150[$	150	125	30.85
$[150, 200[$	200	175	50.00
$[200, 250[$	250	225	69.15
$[250, 300[$	300	275	84.13
$[300, 350[$	350	325	93.32
$[350, 400[$	400	375	97.72
$[400$ and $+$	$-$	$-$	100

The average is now calculated using the central value of the intervals and sample sizes according to the relation we have seen at the beginning of this section (page 546):

$$\hat{\mu}=\frac{\sum\limits_{i=1}^{N} n_i x_i}{\sum\limits_{i=1}^{N} n_i}=\frac{\sum\limits_{i=1}^{N} n_i x_i}{n} \tag{5.7.758}$$

Price of receipts	Center	Relative cumulative frequencies	Calculation
$[0,50[$	25	668	$16,700$
$[50,100[$	75	919	$68,925$
$[100,150[$	125	$1,498$	$187,250$
$[150,200[$	175	$1,915$	$335,125$
$[200,250[$	225	$1,915$	$430,875$
$[250,300[$	275	$1,498$	$411,950$
$[300,350[$	325	919	$411,950$
$[350,400[$	375	440	$165,000$
[400 and $+$	$-$	$-$	$-$
	Sum:	$9,772$	$1,914,500$
		Average:	$\dfrac{1,914,500}{9,772}=195.92$

The average that we have calculated yet is also quite close to the average obtained previously with the Henry's line.

The standard deviation will now be calculated using also the central value of the intervals and sample sizes according to the relation seen at the beginning of this chapter:

$$\hat{\sigma}=\sqrt{\frac{\sum\limits_{i=1}^{N} n_i(x_i-\hat{\mu})}{\sum\limits_{i=1}^{N} n_i}} \tag{5.7.759}$$

Price of receipts	Center	Relative cumulative frequencies	Calculation %
$[0, 50[$	25	668	16, 700
$[50, 100[$	75	919	68, 925
$[100, 150[$	125	1, 498	187, 250
$[150, 200[$	175	1, 915	335, 125
$[200, 250[$	225	1, 915	430, 875
$[250, 300[$	275	1, 498	411, 950
$[300, 350[$	325	919	411, 950
$[350, 400[$	375	440	165, 000
[400 and +	–	228	–
		Variance:	8364.16
		Standard Deviation:	91.45

The standard deviation that we have calculated yet is also quite close to the standard deviation obtained with the method of the Henry's line.

5.7.6.9.7 Q-Q plot

Another way to judge of the quality of fit of experimental data with a theoretical distribution (whatever that is!) is the use of a "quantile-quantile plot" or simply named "q-q plot".

The idea is pretty simple, it based on the comparison the experimental data relatively to the theoretical data that are supposed to follow a particular distribution. Thus, in the case of our example, if we take the values of the mean ($\sim$ 200) and standard deviation ($\sim$ 100) obtained with the Henry's line as theoretical parameters for the Normal distribution, we get:

Price of receipts	Upper experimental limit (imposed)	Relative cumulative frequencies in %	Upper theoretical limit (calculated)
$[0, 50[$	50	6.80%	50.91
$[50, 100[$	100	15.87%	100.02
$[100, 150[$	150	30.85%	149.99
$[150, 200[$	200	50.00%	200
$[200, 250[$	250	69.15%	250.01
$[250, 300[$	300	84.13%	299.98
$[300, 350[$	350	93.32%	350.00
$[350, 400[$	400	97.72%	399.90
[400 and +	–	100%	–

Plotted, this gives us the famous Q-Q plot:

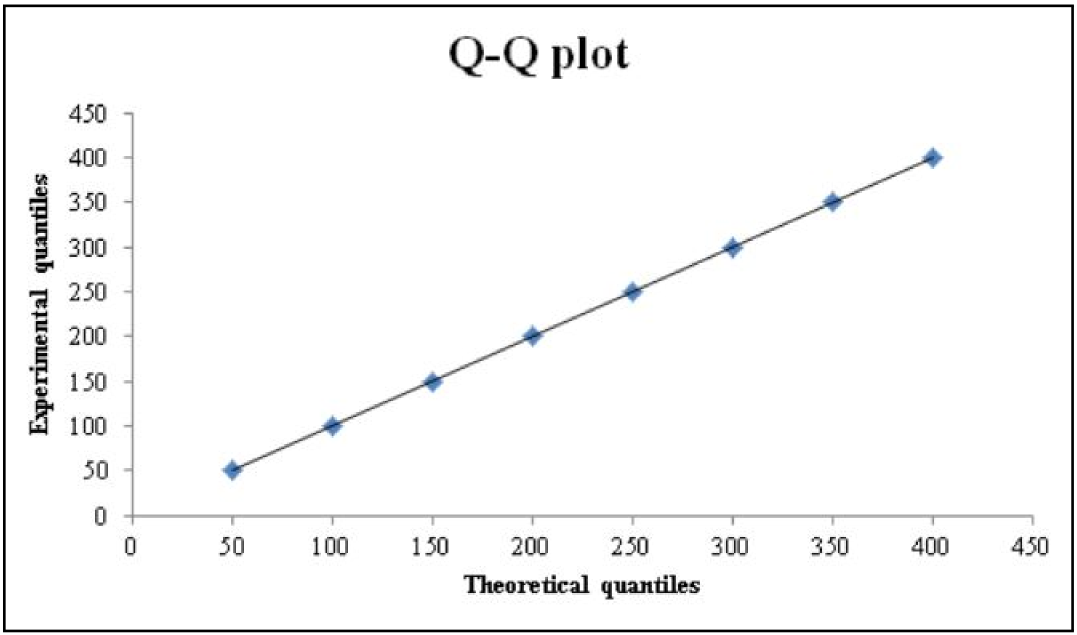

Figure 5.137: **Q-Q plot of the distribution**

And of course we can compare the observed quantiles with the supposed theoretical distribution. More the points will be aligned on the line of unit slope and zero intercept origin, the better will be the fit! It's very visual, very simple and widely used by non-specialists in business statistics.

For the people who may not have access to a spreadsheet or statistical software here is a table that may be useful relatively to the Normal distribution:

NORMAL CUMULATIVE DISTRIBUTION FUNCTION

x	0.00	0.01	0.02	0.03	0.04	0.05	0.06	0.07	0.08	0.09
0.0	0.5000	0.5040	0.5080	0.5120	0.5160	0.5199	0.5239	0.5279	0.5319	0.5359
0.1	0.5398	0.5438	0.5478	0.5517	0.5557	0.5596	0.5636	0.5675	0.5714	0.5753
0.2	0.5793	0.5832	0.5871	0.5910	0.5948	0.5987	0.6026	0.6064	0.6103	0.6141
0.3	0.6179	0.6217	0.6255	0.6293	0.6331	0.6368	0.6406	0.6443	0.6480	0.6517
0.4	0.6554	0.6591	0.6628	0.6664	0.6700	0.6736	0.6772	0.6808	0.6844	0.6879
0.5	0.6915	0.6950	0.6985	0.7019	0.7054	0.7088	0.7123	0.7157	0.7190	0.7224
0.6	0.7257	0.7291	0.7324	0.7357	0.7389	0.7422	0.7454	0.7486	0.7517	0.7549
0.7	0.7580	0.7611	0.7642	0.7673	0.7703	0.7734	0.7764	0.7794	0.7823	0.7852

5.7.6.10 Log-Normal Distribution

We say that a positive random variable X follows a "log-normal function" (or "log-Normal distribution") if by writing:

$$y=\ln(x) \tag{5.7.760}$$

we see that y follows a Normal distribution of mean μ and variance σ^2 (moments of the Normal distribution).

Verbatim by the properties of logarithms, a variable can be modelled by a log-Normal distribution if it results of the multiplication of many small independent factors (property of the product in sum of the logarithms and stability of the Normal distribution by the addition).

The density function of X for $x \geq 0$ is then (this will be justified just further below):

$$\boxed{f(x)=\mathcal{LN}(\mu,\sigma)=\frac{1}{\sigma x\sqrt{2\pi}}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}} \tag{5.7.761}$$

that can be calculated in Microsoft® Excel® 11.8346 with the `LOGNORMDIST( )` function or its inverse by `LOGINV( )`.

This type of scenario is frequently encountered in physics, maintenance techniques, and financial markets in option pricing models (see the respective chapters of this textbook for practical examples), but also sometimes in genetics for modeling mutation rates. There is also an important point to note regarding the log-normal distribution in the later discussion of the central limit theorem!

Let us show that the cumulative probability function corresponds to a Normal distribution if we make the change of variables mentioned above:

$$\int\limits_0^{+\infty} f(x)\mathrm{d}x=\int\limits_0^{+\infty}\frac{1}{\sigma x\sqrt{2\pi}}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_0^{+\infty}\frac{1}{x}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}\mathrm{d}x \tag{5.7.762}$$

by writing:

$$y=\ln(x)\Rightarrow\frac{\mathrm{d}y}{\mathrm{d}x}=\frac{1}{x}\Leftrightarrow \mathrm{d}x=x\mathrm{d}y \tag{5.7.763}$$

and (by definition):

$$x=e^y \tag{5.7.764}$$

we then get:

$$\begin{aligned}\int\limits_0^{+\infty} f(x)\mathrm{d}x&=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_0^{+\infty}\frac{1}{x}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}\frac{1}{x}e^{-\frac{(y-\mu)^2}{2\sigma^2}}x\mathrm{d}y\\&=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}e^{-\frac{(y-\mu)^2}{2\sigma^2}}\mathrm{d}y\end{aligned} \tag{5.7.765}$$

So we indeed fall back on the Normal distribution! Hence the cumulative function is similarly given by:

$$F_X(x)=\frac{1}{2}\left[1+\operatorname{erf}\left(\frac{\ln(x)-\mu}{\sqrt{2}\sigma}\right)\right] \tag{5.7.766}$$

with for reminder:

$$\operatorname{erf}(x)=\frac{2}{\sqrt{\pi}}\int\limits_0^x \exp\left(-t^2\right)\mathrm{d}t \tag{5.7.767}$$

Identically as for the Normal distribution, we get the quantile function immediately:

$$Q_X(p)=\exp\left(\mu+\sqrt{2}\sigma\cdot\operatorname{erf}^{-1}(2p-1)\right) \tag{5.7.768}$$

And again identically as for the Normal distribution, we get then the median that is given by:

$$\operatorname{median}(X)=M_e=e^{\mu} \tag{5.7.769}$$

The mean (average) of X is then given by (the natural logarithm being not defined for $x<0$ we start the integral from zero):

$$\begin{aligned}\mathrm{E}(X)&=\int\limits_0^{+\infty}xf(x)\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_0^{+\infty}x\frac{1}{x}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_0^{+\infty}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}\mathrm{d}x\\&=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}e^{-\frac{(u-\mu)^2}{2\sigma^2}+u}\mathrm{d}u\end{aligned} \tag{5.7.770}$$

where we performed the change of variable:

$$u=\ln(x)\Leftrightarrow x=e^u\qquad x\mathrm{d}u=\mathrm{d}x \tag{5.7.771}$$

The expression:

$$\frac{(u-\mu)^2}{2\sigma^2}+u \tag{5.7.772}$$

moreover being equal to:

$$-\frac{1}{2\sigma^2}\left(\left(u-(\mu+\sigma^2)\right)^2-\left(\mu+\sigma^2\right)^2+\mu^2\right) \tag{5.7.773}$$

the last integral also becomes:

$$\begin{aligned}\mathrm{E}(X)&=\frac{e^{\frac{\left(\mu+\sigma^2\right)^2-\mu^2}{2\sigma\pi}}}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty}e^{-\frac{1}{2\sigma\pi}\left(u-\left(\mu+\sigma^2\right)^2\right)}\mathrm{d}u\\&=e^{\frac{\left(\mu+\sigma^2\right)^2-\mu^2}{2\sigma\pi}}=e^{\mu+\frac{\sigma^2}{2}}\end{aligned} \tag{5.7.774}$$

and where we used the property that emerged during our study of the Normal distribution, that is to say that any integral of the form:

$$\int\limits_{-\infty}^{+\infty} e^{-\frac{(x-c^{\text{te}})^2}{2\sigma^2}}\mathrm{d}x=\sigma\sqrt{2\pi} \tag{5.7.775}$$

always has the same value!

To calculate the variance, recall that for a random variable X, we have the Huygens theorem:

$$\mathrm{V}(X)=\mathrm{E}(X^2)-\mathrm{E}(X)^2 \tag{5.7.776}$$

Let us calculate $\mathrm{E}(X^2)$ by performing similarly to previous developments:

$$\begin{aligned}
\mathrm{E}(X^2)&=\int\limits_0^{+\infty} x^2 f(x)\mathrm{d}x=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_0^{+\infty} xe^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}\mathrm{d}x\\
&=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} e^u e^{-\frac{(u-\mu)^2}{2\sigma^2}}e^u\mathrm{d}u=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} e^{-\frac{(u-\mu)^2}{2\sigma^2}+2u}\mathrm{d}u\\
&=\frac{1}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} e^{-\frac{\left(u-\left(\mu+2\sigma^2\right)\right)^2}{2\sigma^2}}e^{\frac{\left(\mu+2\sigma^2\right)^2-\mu^2}{2\sigma^2}}\mathrm{d}u\\
&=\frac{e^{\frac{\left(\mu+2\sigma^2\right)-\mu^2}{2\sigma^2}}}{\sigma\sqrt{2\pi}}\int\limits_{-\infty}^{+\infty} e^{-\frac{\left(u-\left(\mu+2\sigma^2\right)\right)^2}{2\sigma^2}}\mathrm{d}u\\
&=e^{\frac{\left(\mu+2\sigma^2\right)-\mu^2}{2\sigma^2}}=e^{\frac{4\mu\sigma^2+4\sigma^4}{2\sigma^2}}=e^{2\mu+2\sigma^2}=e^{2(\mu+\sigma^2)}
\end{aligned} \tag{5.7.777}$$

where once again we have the change of variable:

$$u=\ln(x)\Leftrightarrow x=e^u\Rightarrow\mathrm{d}x=e^u\mathrm{d}u \tag{5.7.778}$$

and where we transformed the expression:

$$-\frac{(u-\mu)^2}{2\sigma^2}+2u \tag{5.7.779}$$

as:

$$-\frac{1}{2\sigma^2}\left(\left(u-(\mu+2\sigma^2)\right)^2-\left(\mu+2\sigma^2\right)^2+\mu^2\right) \tag{5.7.780}$$

Then:

$$\begin{aligned}
\mathrm{V}(X)&=\mathrm{E}(X^2)-\mathrm{E}(X)^2=e^{2\mu+2\sigma^2}-\left(e^{\mu+\frac{\sigma^2}{2}}\right)^2\\
&=e^{2\mu+2\sigma^2}-e^{2\mu+\sigma^2}=e^{2\mu+\sigma^2}\left(e^{\sigma^2}-1\right)
\end{aligned} \tag{5.7.781}$$

Here is a plot example of the distribution and cumulative distribution of the Log-Normal function of parameters $(\mu,\sigma)=(0,1)$:

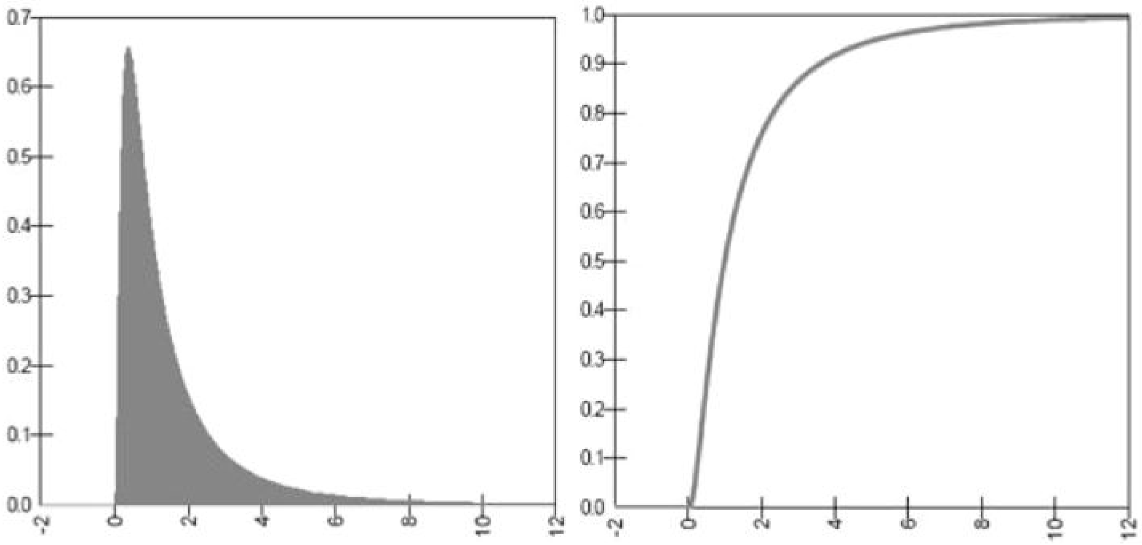

Figure 5.138: **Log-Normal law (mass and cumulative distribution function)**

Remark

Notice that if $y=\log(x)$ follows a $\mathcal{N}(\mu,\sigma)=\mathcal{N}(0,1)$ distribution. Then we have for the mean and variance of the log-Normal distribution:

$$\text{E}(X)=e^{\mu+\frac{\sigma^2}{2}}=e^{0.5}\cong 1.648 \quad\text{and}\quad \text{V}(X)=e^{2\mu+\sigma^2}\left(e^{\sigma^2}-1\right)=e^1\left(e^1-1\right)\cong 4.67 \tag{5.7.782}$$

The median of the log-Normal distribution can be obtained quite straightforward. Let us recall that M_e is given by the value of x for which the first derivative cancels, i.e.:

$$\frac{\partial}{\partial x}\frac{1}{\sigma x\sqrt{2\pi}}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}=0 \tag{5.7.783}$$

We get then immediately:

$$M_e=e^{\mu} \tag{5.7.784}$$

The modal value of the log-Normal distribution is kinda a trap. Some people guess sometimes that the modal value is $M_0=e^{\mu}$ too. But that's wrong! Indeed, let us remind first that the modal value is defined by:

$$\text{mode}(X)=\underset{x}{\arg\max} f_X(x) \tag{5.7.785}$$

And remember that the density function of the log-Normal distribution is:

$$f_X(x)=\frac{1}{x\sigma\sqrt{2\pi}}\cdot\exp\left[-\frac{(\ln(x)-\mu)^2}{2\sigma^2}\right] \tag{5.7.786}$$

Therefore if we calculate the root of the first derivative:

$$\begin{aligned}f'_X(x)=0&=-\frac{1}{x^2\sigma\sqrt{2\pi}}\cdot\exp\left[-\frac{(\ln(x)-\mu)^2}{2\sigma^2}\right]\cdot\left(1+\frac{\ln(x)-\mu}{\sigma^2}\right)\\-1&=\frac{\ln(x)-\mu}{\sigma^2}\\x&=e^{\left(\mu-\sigma^2\right)}\end{aligned} \tag{5.7.787}$$

Hence the modal value of the log-Normal distribution given by:

$$M_0 = e^{\mu-\sigma^2} \tag{5.7.788}$$

5.7.6.11 Continuous Uniform Distribution

Let us choose $a < b$. We define the continuous uniform distribution function or "uniform function" by the relation:

$$\boxed{\mathcal{U}_{a,b}(x) = \frac{1}{b-a}1_{[a,b]}} \tag{5.7.789}$$

where $1_{[a,b]}$ means that outside the domain of definition $[a,b]$ the distribution function is zero. We will find this type of notation later in some other distribution functions. The case $\mathcal{U}_{0,1}(x)$ is commonly named the "standard uniform function".

Obviously the value $1/(b-a)$ is also the value of the modal (mode) value as the distribution is flat!

So we have for the cumulative distribution function:

$$P(X \leq x) = \int_a^x \frac{1}{b-a}1_{[a,b]}\mathrm{d}x = \frac{1}{b-a}1_{[a,b]}\int_a^x \mathrm{d}x = \frac{x_{[a,b]}-a}{b-a} \tag{5.7.790}$$

It is indeed a distribution function because it satisfies (simple integral):

$$\int_{-\infty}^{+\infty} P_{a,b}\mathrm{d}x = \int_{-\infty}^{+\infty}\frac{1}{b-a}1_{[a,b]}\mathrm{d}x = \frac{1}{b-a}1_{[a,b]}\int_a^b \mathrm{d}x = \frac{1}{b-a}1_{[a,b]}x\Big|_a^b = 1_{[a,b]}\frac{b-a}{b-a} = 1 \tag{5.7.791}$$

The continuous uniform function has for expected mean (and as the distribution is symmetric to the mean that's obviously also the value of the median):

$$\begin{aligned}\mu = \mathrm{E}(X) &= \int_a^b xf(x)\mathrm{d}x = \frac{1}{b-a}\int_a^b x\mathrm{d}x = \frac{1}{b-a}\frac{x^2}{2}\Bigg|_a^b = \frac{1}{b-a}\frac{b^2-a^2}{2}\\ &= \frac{1}{b-a}\frac{(b+a)(b-a)}{2} = \frac{a+b}{2}\end{aligned} \tag{5.7.792}$$

and for the variance using the Huygens theorem:

$$\begin{aligned}\mathrm{V}(X)=\mathrm{E}(X^2)-\mathrm{E}(X)^2&=\int\limits_a^b x^2 f(x)\mathrm{d}x-\left(\frac{a+b}{2}\right)^2=\frac{1}{b-a}\int\limits_a^b x^2\mathrm{d}x-\left(\frac{a+b}{2}\right)^2\\&=\frac{1}{b-a}\left.\frac{x^3}{3}\right|_a^b-\left(\frac{a+b}{2}\right)^2=\frac{1}{b-a}\frac{b^3-a^3}{3}-\left(\frac{a+b}{2}\right)^2\\&=\frac{1}{b-a}\frac{(b-a)(b^2+ab+a^2)}{3}-\left(\frac{a+b}{2}\right)^2\\&=\frac{1}{3}(b^2+ab+a^2)-\frac{1}{4}(b^2+2ab+a^2)=\frac{4(b^2+ab+a^2)-3(b^2+2ab+a^2)}{12}\\&=\frac{4b^2+4ab+4a^2-3b^2-6ab-3a^2)}{12}=\frac{b^2-2ab-a^2}{12}=\frac{(b-a)^2}{12}\end{aligned}\tag{5.7.793}$$

Here is a plot example of the distribution and cumulative distribution of the continuous uniform function of parameters $(a,b)=(0,1)$:

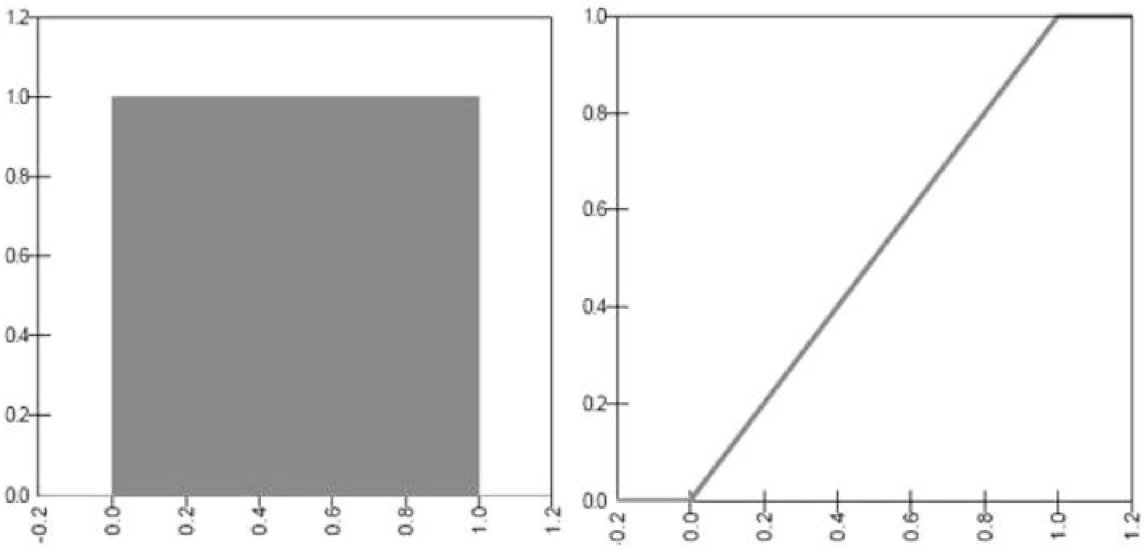

Figure 5.139: **Uniform continuous law (mass and cumulative distribution function)**

Using the same method above we can derive a quite useful special case (that we will use in the chapter of Theoretical Computing). That is the excepted mean of $\mathcal{U}_{0,1}(x)$:

$$\mathrm{E}(\mathcal{U}_{0,1}^2)=\int_0^1 x^2 f(x)\mathrm{d}x=\int_0^1 u^2\cdot 1\mathrm{d}x=\frac{1}{3}\tag{5.7.794}$$

Remark

The uniform function $\mathcal{U}_{a,b}(x)$ is often used in business simulation to indicate that the random variable has equal probabilities to have a value within a certain interval (typically in portfolio returns or in the estimation of project durations). The best example of application is again Crystal Ball or @Risk software that integrate with Microsoft Project.

Let X be a random variable following a continuous uniform distribution:

$$X=\mathcal{U}_{a,b}(x)=\frac{1}{b-a}1_{[a,b]} \tag{5.7.795}$$

Then, the quantile function of X is:

$$Q_X(p)=\begin{cases}-\infty \text{ if } p=0\\ bp+a(1-p) \text{ if } p>0\end{cases} \tag{5.7.796}$$

The cumulative distribution function of the continuous uniform distribution is:

$$F_X(x)=\begin{cases}0 & \text{if } x<a\\ \dfrac{x-a}{b-a} & \text{if } a\leq x\leq b\\ 1 & \text{if } x>b\end{cases} \tag{5.7.797}$$

The quantile function is defined for recall as the smallest x, such that $F_X(x)=p$:

$$Q_X(p)=\min\{x\in\mathbb{R}\mid F_X(x)=p\} \tag{5.7.798}$$

Thus, we have $Q_X(p)=-\infty$, if $p=0$. When $p>0$, it holds that:

$$Q_X(p)=F_X^{-1}(x) \tag{5.7.799}$$

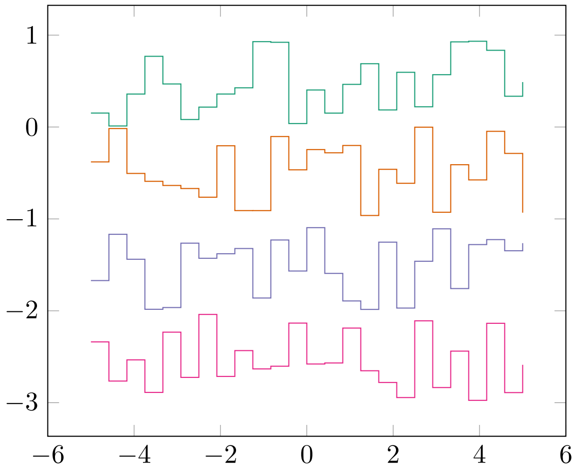
This can be derived by rearranging the cumulative function:

$$p=\frac{x-a}{b-a} \tag{5.7.800}$$

As:

$$x=p(b-a)+a=bp+a(1-p) \tag{5.7.801}$$

The figure below shows the generation (25 trials) of four variables uniformly distributed with different shifts:



We can typically recognize above patterns that are very similar to those observed in nuclear and material laboratories that study the quantum vacuum fluctuations!

Let us see an interesting result of the continuous uniform distribution (and that applies also to the discrete one as well...).

I often hear managers (who consider themselves at high level) that if we have a measure with an equal probability to occur in a closed given interval, then the sum of two such independent random variables have also the same equal probability in the same interval!

Now we will prove here that this is not the case (if someone has a more elegant proof I'm interested)!

Proof 5.47.5. Consider two independent random variables X and Y that follow a uniform distribution in a closed interval $[0, a]$. We are searching the density of their sum will be written:

$$Z = X + Y \tag{5.7.802}$$

Then we have:

$$f_X(x) = f_Y(y) = \begin{cases} +1 & \text{if } 0 \leq x, y \leq a \\ 0 & \text{otherwise} \end{cases} \tag{5.7.803}$$

with the variable:

$$0 \leq z \leq 2a \tag{5.7.804}$$

To calculate the distribution of the sum, remember that we know that in discrete terms this is equivalent to the joint product of probabilities (see section Probabilities page 480) of the occurrence of two continuous variables (remember the same kind of calculation in the discreet form!).

That is to say:

$$f_Z(z) = \int\limits_{-\infty}^{+\infty} f_X(z-y) f_Y(y) \mathrm{d}y \tag{5.7.805}$$

As $f_Y(y) = 1$ if $0 \leq y \leq a$ and 0 otherwise then the product of the previous convolution reduces to:

$$f_Z(z) = \int\limits_0^a f_X(z-y) \mathrm{d}y \tag{5.7.806}$$

The integrand is by definition 0 except by construction in the interval $0 \leq z - y \leq a$ it is then 1.

Let us focus on the limits of the integral that is in this case the only one that is interesting ....

First we make a change of variables by writing:

$$u = z - y \tag{5.7.807}$$

thus:

$$\mathrm{d}u = -\mathrm{d}y \tag{5.7.808}$$

The integral can be then written in this interval after the change of variable:

$$f_Z(z)=\int\limits_0^a f_X(z-y)\mathrm{d}y=-\int\limits_z^{z-a} f_X(u)\mathrm{d}u=\int\limits_z^{z-a}\mathrm{d}u \tag{5.7.809}$$

Remembering that we have seen at the beginning that $0\leq z\leq 2a$, then we have immediately if $z<0$ and $z>2a$ that the integral is zero.

We will consider two cases for the interval because the convolution of these two rectangular functions can be distinguished according to the situation where at first they cross (nest), that is to say where $0\leq z\leq a$, and then recede from each other, that is to say $a<z\leq 2a$.

- In the first case (nest) where $0\leq z\leq a$:

  $$f_Z(u)=\int\limits_{z-a}^{z}\mathrm{d}u=\int\limits_0^z\mathrm{d}u=u|_0^z=z \tag{5.7.810}$$

  where we changed the lower bound to 0 because anyway $f_X(u)$ is zero for any negative value (and when $0\leq z\leq a$,$z-a$ is precisely zero or negative!).

- In the second case (dislocation) where $a<z\leq 2a$:

  $$f_Z(u)=\int\limits_{z-a}^{z}\mathrm{d}u=\int\limits_{z-a}^{a}\mathrm{d}u=a-(z-a)=2a-z \tag{5.7.811}$$

  where we changed the upper terminal a because anyway $f_X(u)$ is zero for any higher value (and when $a\leq z\leq 2a$, z is just larger than a).

  So in the end, we have:

  $$f_Z(z)=\begin{cases} z & \text{if } 0\leq z\leq a\\ 2a-z & \text{if } a\leq z\leq 2a\\ 0 & \text{otherwise}\end{cases} \tag{5.7.812}$$

■ Q.E.D.

This is a particular case, deliberately simplified, of the triangular distribution that we will discover just after...

This result (which may seems perhaps not intuitive) can be checked in a few seconds with a spreadsheet software like Microsoft® Excel® 11.8346 using the `RANDBETWEEN()` and the `FREQUENCY( )` functions.

5.7.6.12 Triangular Distribution

Let $a < c < b$. We define the "triangular distribution" (or "triangular function") by construction based on the following two distribution functions:

$$\boxed{P_{a,c}(x)=\frac{2(x-a)}{(b-a)(c-a)}\cdot 1_{[a,c]} \quad \text{and} \quad P_{c,b}(x)=\frac{2(b-x)}{(b-a)(b-c)}\cdot 1_{]c,b]}} \tag{5.7.813}$$

where a is often assimilated with the optimistic value, c to the modal value and b the pessimistic value.

It is also the only way to write this distribution function if the reader keeps in mind that the base of a triangle of length $c-a$ must have a height h equal to $2/(c-a)$ as its total area is equal to unity (we will soon prove it).

Here is a plot example of the triangular distribution and cumulative distribution for the parameters $(a,c,b)=(0,3,5)$:

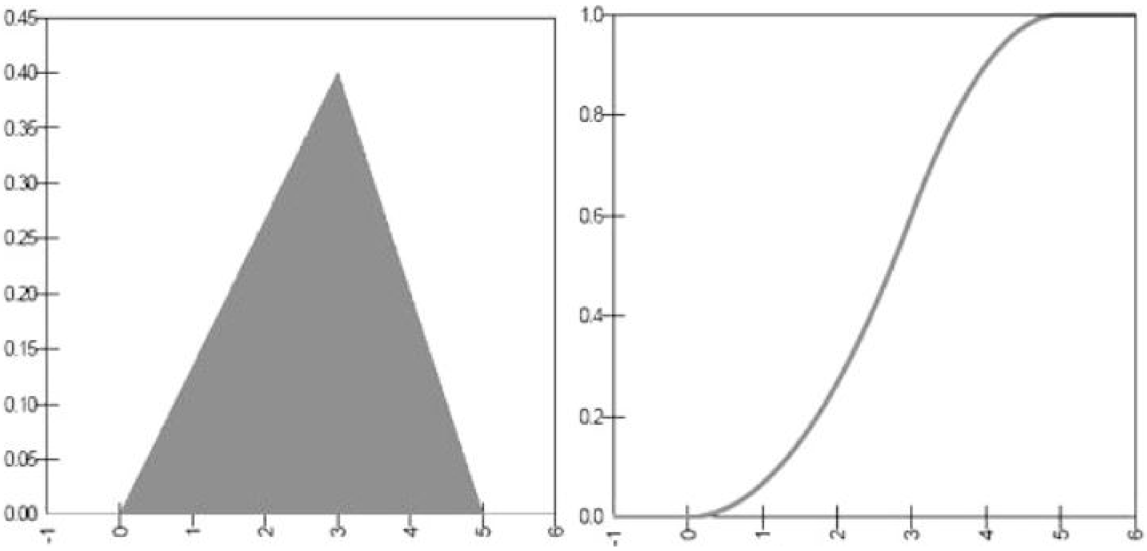


Figure 5.140: **Triangular law (mass and cumulative distribution function)**

The slope of the first straight line (increasing from left) is obviously:

$$\frac{2a}{(b-a)(c-a)} \tag{5.7.814}$$

and the slope of the second straight line (decreasing to the right):

$$\frac{-2}{(b-a)(b-c)} \tag{5.7.815}$$

This function is a distribution function if it satisfies:

$$\rho=\int\limits_{-\infty}^{+\infty}(P_{a,c}(x)+P_{c,b}(x))\mathrm{d}x=1 \tag{5.7.816}$$

It is in this case, simply the area of the triangle which we recall is simply the base multiplied by the height divided by 2 (see section Geometric Shapes page 2896):

$$\rho=\frac{1}{2}\left((b-a)\cdot\frac{2}{b-a}\right)=1 \tag{5.7.817}$$

Remark

This function is widely used in project management in the context of task duration estimations or in industrial simulations. Where a corresponds to the optimistic value, c to the expected value (mode) and the value b to the pessimistic value. The best example of application is again the softwares Crystal Ball or @Risk that are add-ins for Microsoft Project.

The triangular function has also for mean (average):

$$\begin{aligned}
\mu&=\int\limits_{-\infty}^{+\infty}xf(x)\mathrm{d}x=\int\limits_{a}^{c}x\frac{2(x-a)}{(b-a)(c-a)}\mathrm{d}x+\int\limits_{c}^{b}x\frac{2(b-x)}{(b-a)(b-c)}\mathrm{d}x\\
&=\frac{2}{(b-a)(c-a)}\left(\frac{1}{3}x^3-\frac{1}{2}ax^2\right)\Bigg|_a^c+\frac{2}{(b-a)(c-a)}\left(\frac{1}{2}bx^2-\frac{1}{3}x^3\right)\Bigg|_c^b\\
&=\frac{2}{(b-a)(c-a)}\left(\left(\frac{1}{3}c^3-\frac{1}{2}ac^2\right)-\left(\frac{1}{3}a^3-\frac{1}{2}a^3\right)\right)\\
&-\frac{2}{(b-a)(c-a)}\left(\left(\frac{1}{2}b^3-\frac{1}{3}b^3\right)-\left(\frac{1}{2}bc^2-\frac{1}{3}c^3\right)\right)\\
&=2\frac{(b-c)\left(\left(\frac{1}{3}c^3-\frac{1}{2}ac^2\right)+\frac{a^3}{6}\right)+(c-a)\left(\frac{1}{6}b^3-\left(\frac{1}{2}bc^2-\frac{1}{3}c^3\right)\right)}{(b-a)(c-a)(b-c)}\\
&=2\frac{\frac{1}{3}bc^3-\cancel{\frac{1}{2}abc^2}+\frac{ba^3}{6}-\cancel{\frac{1}{3}c^4}+\frac{1}{2}ac^3-\cancel{\frac{a^3c}{6}}}{(b-a)(c-a)(b-c)}\\
&+2\frac{\frac{1}{6}cb^3-\frac{1}{2}bc^3+\cancel{\frac{1}{3}c^4}-\frac{ab^3}{6}+\cancel{\frac{1}{2}abc^2}-\frac{1}{3}ac^3}{(b-a)(c-a)(b-c)}\\
&=\frac{\frac{2}{3}bc^3+ac^3-\frac{1}{3}a^3c+\frac{1}{3}cb^3+\frac{ba^3}{3}-\frac{ab^3}{3}-bc^3-\frac{2}{3}ac^3}{(b-a)(c-a)(b-c)}\\
&=\frac{-\frac{1}{3}bc^3-\frac{1}{3}a^3c+\frac{1}{3}ba^3-\frac{1}{3}\frac{1}{3}ab^3+\frac{1}{3}cb^3+\frac{1}{3}ac^3}{(b-a)(c-a)(b-c)}\\
&=\frac{1}{3}\frac{-bc^3-a^3c+ba^3-ab^3+cb^3+ac^3}{(b-a)(c-a)(b-c)}=\frac{1}{3}\frac{(a+b+c)(b-a)(c-a)(b-c)}{(b-a)(c-a)(b-c)}\\
&=\frac{a+b+c}{3}
\end{aligned} \tag{5.7.818}$$

and for variance:

$$\begin{aligned}\sigma^2&=\int\limits_{-\infty}^{+\infty}(x-\mu)^2f(x)\mathrm{d}x=\int\limits_{a}^{c}(x-\mu)^2\frac{2(x-a)}{(b-a)(c-a)}\mathrm{d}x+\int\limits_{c}^{b}(x-\mu)^2\frac{2(b-x)}{(b-a)(b-c)}\mathrm{d}x\\&=-\frac{1}{6}\frac{c\left(-3c^3+8c^3\mu+4c^2a-6c\mu^2-12c\mu a+12\mu^2a\right)}{(b-a)(c-a)}+\frac{1}{6}\frac{a^2(a^2-4\mu a+6\mu^2}{(b-a)(c-a)}\\&=-\frac{1}{6}\frac{-3c^3+8c^2\mu+4c^2b-6c\mu^2-12c\mu b+12\mu^2b}{(b-a)(c-a)}+\frac{1}{6}\frac{b^2(b^2-4\mu b+6\mu^2)}{(b-a)(c-a)}\\&=\frac{1}{6}b^2+\frac{1}{6}ba-\frac{2}{3}\mu b+\frac{1}{6}a^2-\frac{2}{3}\mu a+\mu^2+\frac{1}{6}ca-\frac{2}{3}c\mu+\frac{1}{6}c^2\end{aligned}\tag{5.7.819}$$

We can replace μ by the result obtained before and we get after simplification (it is boring algebra...):

$$\sigma^2=\frac{a^2+b^2+c^2-ab-ac-bc}{18}\tag{5.7.820}$$

We can show that the sum of two independent random variables, each uniformly distributed on $[a,b]$ (i.e. independent and identically distributed) follows a triangular distribution on $[2a,2b]$ but if they do not have the same limits, then their sum gives something that has no name to my knowledge...

As already mentioned earlier in the previous remark box, the triangular distribution is used a lot in Risk Management by beginners (the level above consisting in using the beta distribution that we will see further below). A quite common figure you can find in project management textbooks for beginners is the impact/probability matrix give below ("impact" is modelled according to the distance between optimistic and pessimistic points):

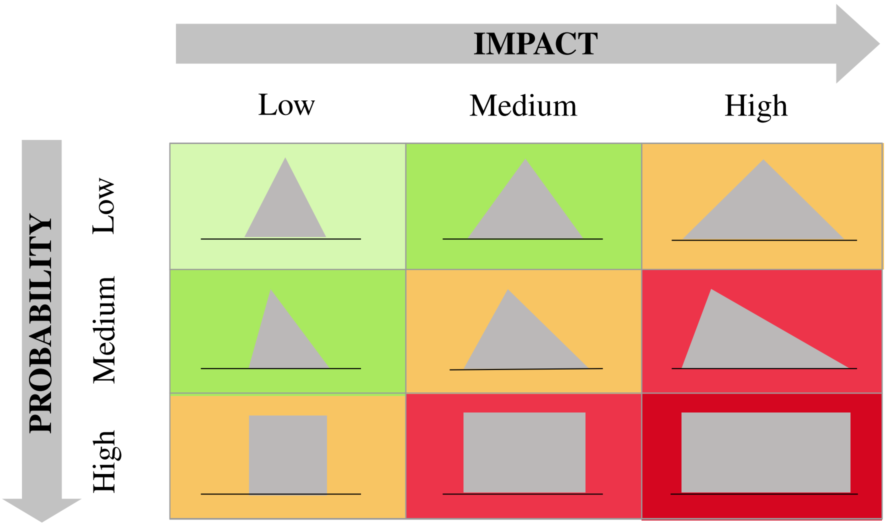

Figure 5.141: **Naive risk matrix in project management (author: Jose Barato)**

The idea of a risk matrix was first developed in the Electronic System Centre, US Air force (see [197]).

5.7.6.13 Pareto Distribution

The "Pareto distribution" (or "Pareto law"), also named "power law" or "scale law" is the formalization of the $80-20$ principle. This decision tool helps determine the critical factors (about 20%) influencing the majority (80%) of the goal.

Remark

This distribution is a fundamental and basic tool in quality management (see Industrial Engineering page 8772 and Quantitative Management page 8095). It is also used in reinsurance. The theory of queues had also some interest in this distribution when some research in the 11990s (holocene calendar) showed that this distribution also seems ton explain well a number of variables observed in the Internet traffic (and more generally on all high speed data networks).

A random variable is said by definition follow a Pareto distribution if its cumulative distribution function is given by:

$$P(X\leqslant x)=1-\left(\frac{x_m}{x}\right)^k \tag{5.7.821}$$

with x that must be greater than or equal to x_m.

The Pareto density function (distribution function) is then given by:

$$f(x)=\frac{\mathrm{d}}{\mathrm{d}x}\left(1-\left(\frac{x_m}{x}\right)^k\right)=-\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{x_m}{x}\right)^k=-x_m^k\frac{\mathrm{d}}{\mathrm{d}x}\frac{1}{x^k}=k\frac{x_m^k}{x^{k+1}} \tag{5.7.822}$$

with $k\in\mathbb{R}_+$ and $x\geq x_m\geq 0$ (then $x>0$).

The Pareto distribution is defined by two parameters, x_m and k (named "Pareto index"). This distribution is also said to be "scale invariant" or "fractal distribution", because of the following property:

$$f\left(c^{te}\cdot x\right)=kx_m^k\left(c^{te}\cdot x\right)^{-k-1}=\left(c^{te}\right)^{-k-1}kx_m^kx^{-k-1}=\left(c^{te}\right)^{-k-1}f(x)\propto f(x) \tag{5.7.823}$$

The Pareto function is also well a distribution function as the cumulative distribution function known we have:

$$\begin{aligned}\int\limits_0^{+\infty}f(x)\mathrm{d}x&=\left.\left(1-\left(\frac{x_m}{x}\right)^k\right)\right|_{x_m}^{+\infty}\\&=\left(1-\left(\frac{x_m}{+\infty}\right)^k\right)-\left(1-\left(\frac{x_m}{x_m}\right)^k\right)=(1-0)-(1-1^k)=1\end{aligned} \tag{5.7.824}$$

The expected mean is given by:

$$\mu=\mathrm{E}(X)=\int\limits_{x_m}^{+\infty}xf(x)\mathrm{d}x=\int\limits_{x_m}^{+\infty}xk\frac{x_m^k}{x^{k+1}}\mathrm{d}x=kx_m^k\int\limits_{x_m}^{+\infty}x\frac{1}{x^k}\mathrm{d}x=-\left.\frac{kx_m^k}{k-1}\frac{1}{x^{k-1}}\right|_{x_m}^{+\infty}=\frac{kx_m}{k-1} \tag{5.7.825}$$

if $k > 1$. If $k \leq 1$, the mean does not exist.

To calculate the variance, using the Huygens theorem:

$$\mathrm{V}(X) = \mathrm{E}(X^2) - \mathrm{E}(X)^2 \tag{5.7.826}$$

we get:

$$\mathrm{E}(X^2) = \int\limits_{x_m}^{+\infty} x^2 f(x)\mathrm{d}x = kx_m^k \int\limits_{x_m}^{+\infty} \frac{1}{x^{k-1}}\mathrm{d}x = -\frac{kx_m^k}{k-2}\frac{1}{x^{k-2}}\Bigg|_{x_m}^{+\infty} = \frac{kx_m^2}{k-2} \tag{5.7.827}$$

if $k > 2$. If $k \leq 2$, $\mathrm{E}(X^2)$ doesn't exist!

So if $k > 2$:

$$\sigma^2 = \mathrm{V}(X) = \frac{kx_m^2}{k-2} - \left(\frac{kx_m}{k-1}\right)^2 = \frac{kx_m^2}{(k-1)^2(k-2)} \tag{5.7.828}$$

If $k \leq 2$, the variance doesn't exists.

Here is a plot example of the Pareto distribution and cumulative distribution for the parameters $(x, x_m, k) = (x, 1, 2)$:

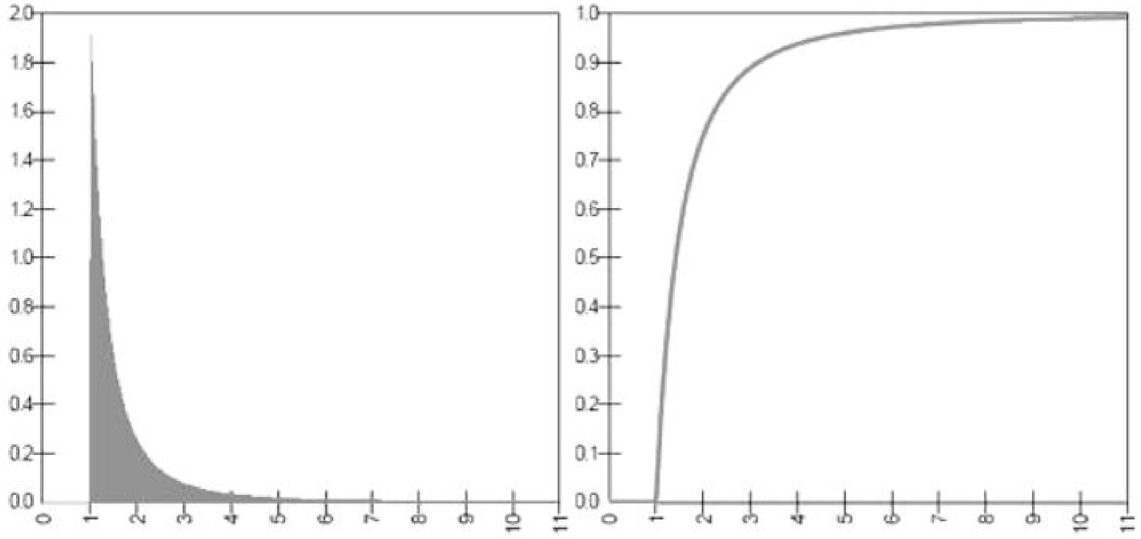

Figure 5.142: **Pareto law (mass and cumulative distribution function)**

Remark

See that when $k \rightarrow +\infty$ the distribution approaches $\delta(x - x_m)$ where δ is the Dirac delta function.

There is another important way to deduce the family of Pareto distributions that allows us to understand many things about other distributions and that is often presented as follows:

Let us write x_0 the threshold beyond which we calculate the mean of the considered quantity, and $\mathrm{E}(Y)$ the mean beyond this threshold x_0 as it is proportional (linearly dependent) to the chosen threshold:

$$\mathrm{E}(Y) = ax_0 + b \tag{5.7.829}$$

This functional relation expresses the idea that the conditional mean beyond the threshold x_0 is a multiple of this threshold plus a constant, that is to say a linear function of the threshold.

Thus, in project management, for example, we could say that once a certain threshold of time is exceeded, the expected duration is a multiple of this threshold plus a constant.

If a linear relation of this type exists and is satisfied, then we talk about a probability distribution in the form of a generalized Pareto distribution.

Consider the mean of the Bayesian conditional function given by (see section Probabilities page 499):

$$\mathrm{E}(Y)=\frac{1}{P(X\geq x_0)}\int\limits_{x_0}^{+\infty} yf(y)\mathrm{d}y \tag{5.7.830}$$

where the notation on the left hand side is somewhat shortened but the reader will implicitly understand that it is a conditional expectation.

If we write $F(y)$ the cumulative distribution function $f(y)$, then we have by definition:

$$\mathrm{d}F(y)=f(y)\mathrm{d}y \tag{5.7.831}$$

Thus:

$$\mathrm{E}(Y)=\frac{1}{P(X\geq x_0)}\int\limits_{x_0}^{+\infty} y\mathrm{d}F(y) \tag{5.7.832}$$

and if we define:

$$\bar{F}_X(x)=P(X\geq x_0)=1-F_X(x) \tag{5.7.833}$$

what we can assimilate to the "tail of the distribution".

We get:

$$\mathrm{E}(Y)=\frac{1}{\bar{F}(x_0)}\int\limits_{x_0}^{+\infty} y\mathrm{d}F(y) \tag{5.7.834}$$

and therefore we seek the very special case where:

$$\mathrm{E}(Y)=\frac{1}{\bar{F}(x_0)}\int\limits_{x_0}^{+\infty} y\mathrm{d}F(y)=ax+b \tag{5.7.835}$$

this is to say:

$$\int\limits_{x_0}^{+\infty} y\mathrm{d}F(y)=(ax+b)\bar{F}(x_0) \tag{5.7.836}$$

Differentiating with respect to x, we find:

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\int_{x_0}^{+\infty} y\mathrm{d}F(y)\right)=\frac{\mathrm{d}}{\mathrm{d}x}\left((ax+b)\bar{F}(x_0)\right) \tag{5.7.837}$$

The derivative of the integral defined above will be the derivative of a constant (valorisation of the integral in $+\infty$) minus the derivative of the analytical expression of the integral for x_0. So we have:

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\int_{x_0}^{+\infty} y\mathrm{d}F(y)\right)=\frac{\mathrm{d}}{\mathrm{d}x}\left(\int_{x_0}^{+\infty} yf(y)\mathrm{d}y\right)=-xf(x)=-x\frac{\mathrm{d}F(x)}{\mathrm{d}x}=a\bar{F}(x)+(ax+b)\frac{\mathrm{d}\bar{F}(x)}{\mathrm{d}x} \tag{5.7.838}$$

Thus:

$$-x\frac{\mathrm{d}F(x)}{\mathrm{d}x}=a\bar{F}(x)+(ax+b)\frac{\mathrm{d}\bar{F}(x)}{\mathrm{d}x} \tag{5.7.839}$$

and as:

$$\mathrm{d}F=\mathrm{d}(1-\bar{F})=-\mathrm{d}\bar{F} \tag{5.7.840}$$

it comes:

$$x\frac{\mathrm{d}\bar{F}}{\mathrm{d}x}=a\bar{F}(x)+(ax+b)\frac{\mathrm{d}\bar{F}}{\mathrm{d}x} \tag{5.7.841}$$

After simplification and rearrangement we obtain:

$$a\bar{F}(x)\mathrm{d}x=-\left(x(a-1)+b\right)\mathrm{d}\bar{F}(x) \tag{5.7.842}$$

which is a differential equation in $\bar{F}(x)$. Its Resolution provides all forms of seek Pareto distributions, according to the values taken by the parameters a and b.

To solve this differential equation, consider the special case where $a>1, b=0$. Then we have:

$$a\bar{F}(x)\mathrm{d}x=-x(a-1)\mathrm{d}\bar{F}(x) \tag{5.7.843}$$

By writing:

$$k=\frac{a}{a-1} \tag{5.7.844}$$

We then get:

$$-\frac{1}{x}\mathrm{d}x=\frac{1}{k}\frac{1}{\bar{F}(x)}\mathrm{d}\bar{F}(x) \tag{5.7.845}$$

and therefore:

$$-\ln(x)=\frac{1}{k}\ln(\bar{F}(x))+c^{te} \tag{5.7.846}$$

It comes:

$$e^{\ln\left(\frac{1}{x}\right)}=e^{\frac{1}{k}\ln(\bar{x})+c^{te}}=e^{\frac{1}{k}\ln\left(\bar{F}(x)\right)}e^{c^{te}} \tag{5.7.847}$$

and therefore:

$$\ln\left(\frac{1}{x}\right)=\bar{F}(x)^{\frac{1}{k}}c^{te} \tag{5.7.848}$$

So we have:

$$\bar{F}(x)=\left(\frac{c^{te}}{x}\right)^k=\left(\frac{x_m}{x}\right)^k \tag{5.7.849}$$

Then it comes form the cumulative distribution function:

$$F(x)=1-\bar{F}(x)=1-\left(\frac{x_m}{x}\right)^k \tag{5.7.850}$$

If we seek for the distribution function, we derive by x to get:

$$f(x)=\frac{\mathrm{d}F(x)}{\mathrm{d}x}=k\frac{x_m^k}{x^{k+1}} \tag{5.7.851}$$

This is the Pareto distribution we have used since the beginning and named "Pareto distribution of type I" (we won't see in this textbook those of type II).

An interesting thing to observes is the case of the resolution of the following differential equation:

$$a\bar{F}(x)\mathrm{d}x=-(x(a-1)+b)\mathrm{d}\bar{F}(x) \tag{5.7.852}$$

when $a=1,b>0$. The differential equation is then reduced to:

$$\bar{F}(x)\mathrm{d}x=-b\mathrm{d}\bar{F}(x) \tag{5.7.853}$$

Thus:

$$-\frac{1}{b}\mathrm{d}x=\frac{1}{\bar{F}(x)}\mathrm{d}\bar{F}(x) \tag{5.7.854}$$

After integration:

$$-\frac{1}{b}x=\ln(\bar{F}(x)) \tag{5.7.855}$$

and therefore:

$$\bar{F}(x)=e^{-\frac{1}{b}x} \tag{5.7.856}$$

If we make a small change in notation:

$$\bar{F}(x)=e^{-\lambda x} \tag{5.7.857}$$

and that we write the distribution function:

$$F(x)=1-\bar{F}(x)=1-e^{-\lambda x} \tag{5.7.858}$$

and by derivating we get the distribution function of the exponential distribution:

$$F(x)=\lambda e^{-\lambda x} \tag{5.7.859}$$

So the exponential distribution has a conditional mean threshold that is equal to:

$$\mathrm{E}(Y)=ax_0+b\underset{a=1}{=}x_0+b\underset{b=\frac{1}{\lambda}}{=}x_0+\frac{1}{b}=x_0+\sigma \tag{5.7.860}$$

So the conditional mean threshold is equal to itself plus the standard deviation of the distribution.

5.7.6.14 Exponential Distribution

We define the "exponential distribution" (or "exponential law") by the following distribution function:

$$\boxed{P(x)=\lambda e^{-\lambda x}1_{[0,+\infty]}} \tag{5.7.861}$$

with $\lambda>0$ that as we will immediately see is in the fact that the inverse of the mean and where x is a random variable without memory. This law is also sometimes denoted $\mathcal{E}(\lambda)$.

In fact the exponential distribution naturally appears from simple developments (see the Nuclear Physics chapter for example) under assumptions that impose a constance in the aging of phenomenon. In the section of Quantitative Management, we have also proved in detail in the section on the theory of queues (page 8149), that this law was without memory. That is to say, that the cumulative probability of a phenomenon occurs between the time t and $t+s$, if it is not realized before, is the same as that the cumulative probability of occurring between the time 0 and s.

Remarks

R1. This function is occurring frequently in nuclear physics (see chapter of the same name) or quantum physics (see also chapter of the same name) as well in reliability (see section Quantitative Management page 8673) or in the theory of queues (see section Quantitative Management page 8141).

R2. We can get this distribution in Microsoft® Excel® 11.8346 with the `EXPONDIST( )` function.

It is also really a distribution function because it verifies:

$$\int\limits_{-\infty}^{+\infty} P_\lambda(x)\mathrm{d}x=\lambda\int\limits_{0}^{+\infty} e^{-\lambda x}\mathrm{d}x=\lambda\left(-\frac{1}{\lambda}\right)e^{-\lambda x}\Big|_0^{+\infty}=-\left(e^{-\infty x}-e^{0x}\right)=-(0-1)=1 \tag{5.7.862}$$

The exponential distribution has for expected mean using integration by parts:

$$\begin{aligned}\mu&=\int\limits_{-\infty}^{+\infty} xP_\lambda(x)\mathrm{d}x=\lambda\int\limits_{0}^{+\infty} xe^{-\lambda x}\mathrm{d}x=-\left.xe^{-\lambda x}\right|_0^{+\infty}-\int\limits_{0}^{+\infty}-e^{-\lambda x}\mathrm{d}x=\int\limits_{0}^{+\infty}e^{-\lambda x}\mathrm{d}x\\&=-\frac{1}{\lambda}\left.e^{-\lambda x}\right|_0^{+\infty}=\frac{1}{\lambda}\end{aligned} \tag{5.7.863}$$

and for variance using once again the Huygens relation:

$$\mathrm{V}(X)=\mathrm{E}(X^2)-\mathrm{E}(X)^2 \tag{5.7.864}$$

it remains for us to only the to calculate:

$$\mathrm{E}(X^2)=\int\limits_{0}^{+\infty}\lambda x^2e^{-\lambda x}x \tag{5.7.865}$$

A variable change $y = \lambda$ leads us to:

$$\mathrm{E}(X^2) = \frac{1}{\lambda^2}\int_0^{+\infty} y^2 e^{-y}\mathrm{d}y \tag{5.7.866}$$

A double integration by parts gives us:

$$\begin{gathered}\int_a^b f(t)g'(t)\mathrm{d}t = f(t)g(t)|_a^b - \int_a^b f'(t)g(t)\mathrm{d}t \\ \int_0^{+\infty} y^2e^{-y}\mathrm{d}y = -y^2e^{-y}|_0^{-\infty} + 2\int_0^{+\infty} ye^{-y}\mathrm{d}y = 2\left[-ye^{-y}|_0^{+\infty}\right] + 2\int_0^{+\infty} e^{-y}\mathrm{d}y = 2\end{gathered} \tag{5.7.867}$$

Hence:

$$\mathrm{E}(X^2) = \frac{2}{\lambda^2} \tag{5.7.868}$$

we have therefore:

$$\mathrm{V}(X) = \mathrm{E}(X^2) - \mathrm{E}(X)^2 = \frac{2}{\lambda^2} - \left(\frac{1}{\lambda}\right)^2 = \frac{1}{\lambda^2} \tag{5.7.869}$$

So the standard deviation (square root of the variance for recall) and mean have exactly the same expression!

Here is a plot example of the exponential distribution and cumulative distribution for the parameter $\lambda = 1$:

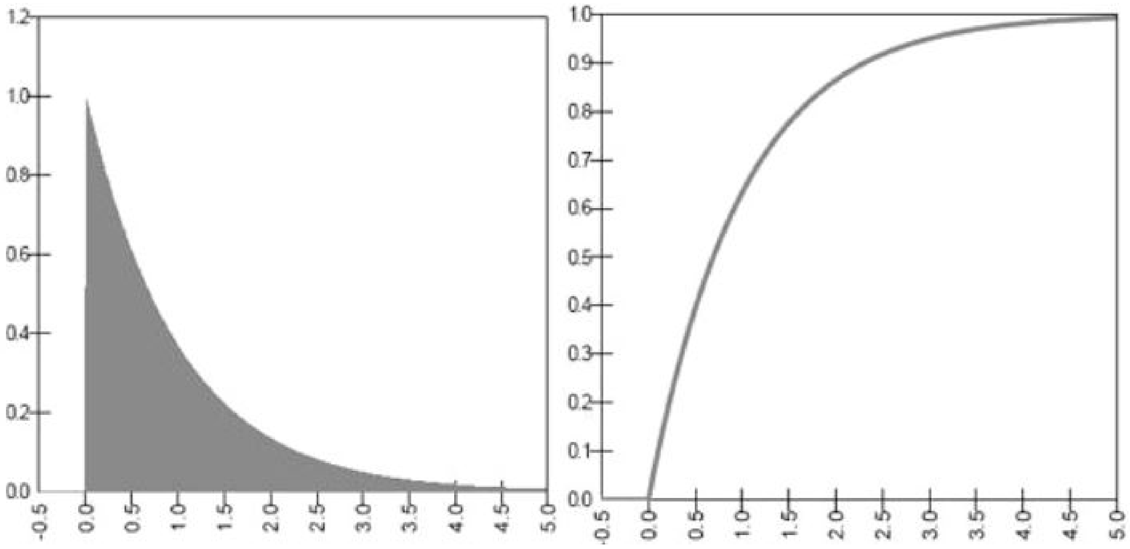

Figure 5.143: Exponential law (mass and cumulative distribution function)

Now let us determine the cumulative distribution function of the exponential law:

$$P(X \leqslant x) = \int_0^x \lambda e^{-\lambda t}\mathrm{d}t = \lambda\int_0^x e^{-\lambda t}\mathrm{d}t = \lambda\left(-\frac{1}{\lambda}e^{-\lambda t}\right)\Big|_0^x = 1 - e^{-\lambda x} \tag{5.7.870}$$

Let X be a random variable following an exponential distribution:

$$X \sim \text{Exp}(\lambda) \tag{5.7.871}$$

Then, the quantile function of X is:

$$Q_X(p) = \begin{cases} -\infty, \text{ if } p = 0 \\ -\dfrac{\ln(1-p)}{\lambda}, \text{ if } p > 0 \end{cases} \tag{5.7.872}$$

Indeed, the cumulative distribution function of the exponential distribution is as we have just shown:

$$F_X(x) = \begin{cases} 0, \text{ if } x < 0 \\ 1 - \exp[-\lambda x], \text{ if } x \geq 0 \end{cases} \tag{5.7.873}$$

Remember that the quantile function $Q_X(p)$ is defined as the smallest x, such that $F_X(x) = p$:

$$Q_X(p) = \min\{x \in \mathbb{R} \mid F_X(x) = p\} \tag{5.7.874}$$

Thus, we have $Q_X(p) = -\infty$, if $p = 0$. When $p > 0$, it holds that:

$$Q_X(p) = F_X^{-1}(x) \tag{5.7.875}$$

This can be derived by rearranging the equation :

$$\begin{aligned} p &= 1 - \exp[-\lambda x] \\ \exp[-\lambda x] &= 1 - p \\ -\lambda x &= \ln(1-p) \\ x &= -\frac{\ln(1-p)}{\lambda} \end{aligned} \tag{5.7.876}$$

Let X be a random variable following an exponential distribution:

$$X \sim e^{\lambda} \tag{5.7.877}$$

Then, the median of X is:

$$\text{median}(X) = M_e(X) = \frac{\ln(2)}{\lambda} \tag{5.7.878}$$

Indeed, remember that the median is the value at which the cumulative distribution function is $1/2$:

$$F_X(\text{median}(X)) = \frac{1}{2} \tag{5.7.879}$$

The cumulative distribution function of the exponential distribution is as we have just shown earlier above:

$$F_X(x) = 1 - e^{-\lambda x}, \quad x \geq 0 \tag{5.7.880}$$

Thus, the inverse cumulative distribution function is:

$$x = -\frac{\ln(1-p)}{\lambda} \tag{5.7.881}$$

and setting $p = 1/2$, we get:

$$\text{median}(X) = -\frac{\ln\left(1-\dfrac{1}{2}\right)}{\lambda} = \frac{\ln(2)}{\lambda} \tag{5.7.882}$$

Let X be a random variable still following an exponential distribution:

$$X \sim e^{\lambda} \tag{5.7.883}$$

Then, the mode of X is:

$$\text{mode}(X) = M_0(X) = 0 \tag{5.7.884}$$

Indeed, remember that the mode is the value which maximizes the probability density function:

$$\text{mode}(X) = \underset{x}{\arg\max} f_X(x) \tag{5.7.885}$$

The probability density function of the exponential distribution is for reminder:

$$f_X(x) = \begin{cases} 0, \text{ if } x < 0 \\ \lambda e^{-\lambda x}, \text{ if } x \geq 0 \end{cases} \tag{5.7.886}$$

Since:

$$f_X(0) = \lambda \tag{5.7.887}$$

and:

$$0 < e^{-\lambda x} < 1 \quad \text{for any} \quad x > 0 \tag{5.7.888}$$

it follows that:

$$\text{mode}(X) = 0 \tag{5.7.889}$$

Let us now compute the skewness of the exponential distribution as defined by (see page 636):

$$\gamma_1 = \frac{\text{E}\left(X^3\right) - 3\mu\sigma^2 - \mu^3}{\sigma^3} \tag{5.7.890}$$

where μ and σ are respectively the mean and standard deviation of X. Since X follows an exponential distribution, the mean of X is given by:

$$\mu = \text{E}(X) = \frac{1}{\lambda} \tag{5.7.891}$$

and the standard deviation of X is given by:

$$\sigma = \sqrt{\text{V}(X)} = \sqrt{\frac{1}{\lambda^2}} = \frac{1}{\lambda} \tag{5.7.892}$$

Therefore:

$$\begin{aligned}\gamma_1 &= \frac{\text{E}\left(X^3\right) - 3\mu\sigma^2 - \mu^3}{\sigma^3} = \frac{\text{E}\left(X^3\right)}{\sigma^3} - \frac{3\mu\sigma^2 + \mu^3}{\sigma^3} \\ &= \frac{\text{E}\left(X^3\right)}{\left(\frac{1}{\lambda}\right)^3} - \frac{3\left(\frac{1}{\lambda}\right)\left(\frac{1}{\lambda}\right)^2 + \left(\frac{1}{\lambda}\right)^3}{\left(\frac{1}{\lambda}\right)^3} = \lambda^3 \cdot \text{E}\left(X^3\right) - \frac{\frac{3}{\lambda^3} + \frac{1}{\lambda^3}}{\frac{1}{\lambda^3}} \\ &= \lambda^3 \cdot \text{E}\left(X^3\right) - 4\end{aligned} \tag{5.7.893}$$

Thus, the remaining work is to compute $\mathrm{E}\left(X^3\right)$. To do this, we use the moment-generating function of the exponential distribution to calculate:

$$\mathrm{E}\left(X^3\right) = M'_X(0) \tag{5.7.894}$$

based on the relationship between raw moment and moment-generating function. First, we differentiate the moment-generating function of the exponential distribution (see page 933 where we have derived the moment generating function of the Gamma distribution and if we put $\alpha = 1$ we get that of the exponential distribution!):

$$M_X(t) = \frac{\lambda}{\lambda - t} = \lambda(\lambda - t)^{-1} \tag{5.7.895}$$

with respect to t. Using the chain rule gives:

$$M'_X(t) = -1 \cdot \lambda(\lambda - t)^{-2} \cdot (-1) = \lambda(\lambda - t)^{-2} \tag{5.7.896}$$

We continue using the chain rule to obtain the second derivative:

$$M''_X(t) = -2 \cdot \lambda(\lambda - t)^{-3} \cdot (-1) = 2\lambda(\lambda - t)^{-3} \tag{5.7.897}$$

Finally, one more application of the chain rule gives us the third derivative:

$$M'''_X(t) = -3 \cdot 2\lambda(\lambda - t)^{-4} \cdot (-1) = 6\lambda(\lambda - t)^{-4} = \frac{6\lambda}{(\lambda - t)^4} \tag{5.7.898}$$

Therefore:

$$\mathrm{E}\left(X^3\right) = M'''_X(0) = \frac{6\lambda}{(\lambda - 0)^4} = \frac{6\lambda}{\lambda^4} = \frac{6}{\lambda^3} \tag{5.7.899}$$

We now substitute this relation into the skewness, giving:

$$\gamma_1 = \lambda^3 \cdot \mathrm{E}\left(X^3\right) - 4 = \lambda^3 \cdot \left(\frac{6}{\lambda^3}\right) - 4 = 6 - 4 = 2 \tag{5.7.900}$$

Remark

We will see later that the exponential distribution is a special case of a more general distribution which is the chi-square distribution, the chi-square is also a special case of a more general distribution that is the Gamma distribution. This is a very important property used in the "Poisson test" for rare events (see also below).

5.7.6.15 Cauchy Distribution

Let X, Y be two independent random variables following a Normal reduced centered distribution (with zero mean and unit variance). Thus the density function is given for each variable by:

$$f_X(x) = f_Y(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} \tag{5.7.901}$$

The random variable:

$$T=\frac{X}{|Y|} \tag{5.7.902}$$

(the absolute value will be useful in an integral during a change of variable) follows a characteristic appearance named the "standard Cauchy distribution" (or "standard Cauchy law") or even "standard Lorentz law" (as we took as starting point the special case of two centred reduced Normal laws!).

Let us now determine its density function f. To do this, recall that f is determined by the (general) relation:

$$\forall t \in \mathbb{R}, P(T \leqslant t)=\int\limits_{-\infty}^{t} f(x)\mathrm{d}x \tag{5.7.903}$$

So (application of elementary differential calculus):

$$f(t)=\frac{\mathrm{d}}{\mathrm{d}t}P(T \leq t) \tag{5.7.904}$$

in the case where f is continuous.

Since X and Y are independent, the density function of the random vector is given by the third axioms of probabilities (see section Probabilities page 480):

$$(x,y)\mapsto f_X(x)\cdot f_Y(x) \tag{5.7.905}$$

therefore:

$$P(T\leqslant t)=P\left(\frac{X}{|Y|}<t\right)=P(X\leqslant t|Y|)=\int\limits_D f_X(x)\cdot f_Y(x)\mathrm{d}x\mathrm{d}y \tag{5.7.906}$$

where $D=\{(x,y)|x<t|y|\}$. This last integral becomes:

$$\int\limits_D f_X(x)\cdot f_Y(x)\mathrm{d}x\mathrm{d}y=\int\limits_{-\infty}^{+\infty}\int\limits_{-\infty}^{t\cdot|y|} f_X(x)\cdot f_Y(x)\mathrm{d}x\mathrm{d}y \tag{5.7.907}$$

Let us make the following change of variables $x=u|y|$ in the inner integral. We obtain:

$$P(T\leqslant t)=\int\limits_{-\infty}^{+\infty}\int\limits_{-\infty}^{t} f_X(u\cdot|y|)\cdot f_Y(y)|y|\mathrm{d}u\mathrm{d}y=\int\limits_{-\infty}^{t}\int\limits_{-\infty}^{+\infty} f_X(u\cdot|y|)\cdot f_Y(y)|y|\mathrm{d}y\mathrm{d}u \tag{5.7.908}$$

Therefore:

$$f(t)=\frac{\mathrm{d}}{\mathrm{d}t}P(T\leqslant t)=\int\limits_{-\infty}^{+\infty} f_X(t\cdot|y|)\cdot f_Y(y)|y|\mathrm{d}y=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} e^{-\frac{y^2(t^2+1)}{2}}|y|\mathrm{d}y \tag{5.7.909}$$

Now the absolute value will be useful to write:

$$f(t)=\frac{1}{2\pi}\int\limits_{-\infty}^{+\infty} e^{-\frac{y^2(t^2+1)}{2}}|y|\mathrm{d}y=-\frac{1}{2\pi}\int\limits_{-\infty}^{0} e^{-\frac{y^2(t^2+1)}{2}}y\mathrm{d}y+\frac{1}{2\pi}\int\limits_{0}^{+\infty} e^{-\frac{y^2(t^2+1)}{2}}y\mathrm{d}y \qquad (5.7.910)$$

For the first integral we have:

$$\frac{1}{2\pi}\int\limits_{-\inf}^{0} e^{-\frac{y^2(t^2+1)}{2}}y\mathrm{d}y=\left.\frac{e^{-\frac{y^2(t^2+1)}{2}}}{t^2+1}\right|_{-\infty}^{0}=-\frac{1}{t^2+1}+\frac{1}{t^2+1}=0 \qquad (5.7.911)$$

It remains therefore only the second integral and making the change of variable $v=y^2$, we get:

$$f(t)=\frac{1}{2\pi}\int\limits_{0}^{+\infty} e^{-\frac{\nu(t^2+1)}{2}}\mathrm{d}\nu=-\left.\frac{e^{-\frac{\nu(t^2+1)}{2}}}{\pi(t^2+1)}\right|_{0}^{+\infty}=\frac{1}{\pi(t^2+1)} \qquad (5.7.912)$$

What we will denote thereafter (to respect the notations adopted so far):

$$\boxed{P(x)=\frac{1}{\pi(x^2+1)}} \qquad (5.7.913)$$

and that is simply the so named "standard Cauchy distribution" (as we took as starting point two centred reduced Normal laws!).

It is also effectively a distribution function because it verifies (see section Differential and Integral Calculus page 1534):

$$\int\limits_{-\infty}^{+\infty} P(x)\mathrm{d}x=\frac{1}{\pi}\int\limits_{-\infty}^{+\infty}\frac{1}{x^2+1}\mathrm{d}x=\frac{1}{\pi}(\arctan(+\infty)-\arctan(-\infty))=\frac{1}{\pi}\left(\frac{\pi}{2}-\left(-\frac{\pi}{2}\right)\right)=1 \qquad (5.7.914)$$

It is obvious that we get therefore for the cumulative distribution function:

$$\begin{aligned}P(X\leq x)&=\int\limits_{-\infty}^{x} P(x)\mathrm{d}x=\frac{1}{\pi}\int\limits_{-\infty}^{x}\frac{1}{x^2+1}\mathrm{d}x=\frac{1}{\pi}(\arctan(x)-\arctan(-\infty))=\\&=\frac{1}{\pi}\left(\arctan(x)-\left(-\frac{\pi}{2}\right)\right)=\frac{1}{\pi}\arctan(x)+\frac{1}{2}\end{aligned} \qquad (5.7.915)$$

Here is plot example of the Cauchy distribution:

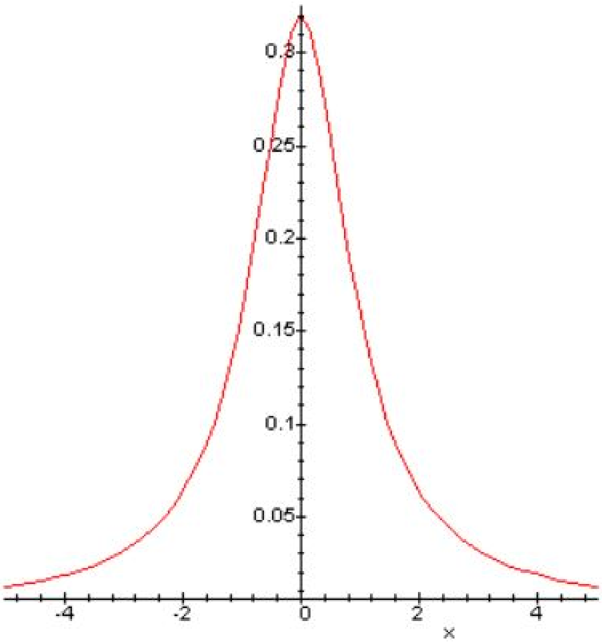

Figure 5.144: **Cauchy law (mass function)**

The Cauchy distribution has for expected mean:

$$\begin{aligned}\mu &= \int_{-\infty}^{+\infty} xP(x)\mathrm{d}x = \frac{1}{\pi}\int_{-\infty}^{+\infty}\frac{x}{1+x^2}\mathrm{d}x = \frac{1}{\pi}\left(\int_{-\infty}^{0}\frac{x}{1+x^2}\mathrm{d}x + \int_{0}^{+\infty}\frac{x}{1+x^2}\mathrm{d}x\right)\\ &= \frac{1}{2\pi}\left(\ln(1+x^2)\big|_{-\infty}^{0} + \ln(1+x^2)\big|_{0}^{+\infty}\right) = \frac{1}{2\pi}(-\ln(\infty)+\ln(\infty)) = 0\end{aligned} \tag{5.7.916}$$

Caution!!!! The above calculations do not give zero in facts because the subtraction of infinite is not zero but indeterminate! The Cauchy distribution therefore and strictly speaking does not admits an expected mean!

Thus, even if we can build a variance:

$$\begin{aligned}\sigma^2 &= \int_{-\infty}^{+\infty}(x-\mu)^2 f(x)\mathrm{d}x = \int_{-\infty}^{+\infty} x^2P(x)\mathrm{d}x = \frac{1}{\pi}\int_{-\infty}^{+\infty}\frac{x^2}{1+x^2}\mathrm{d}x = \frac{1}{\pi}\int_{-\infty}^{+\infty}\left(1-\frac{1}{1+x^2}\right)\mathrm{d}x\\ &= \frac{2}{\pi}\lim_{t\rightarrow+\infty}\int_{0}^{t}\left(1-\frac{1}{1+x^2}\right)\mathrm{d}x = 2\pi\lim_{t\rightarrow+\infty}(t-\arctan(t)) = +\infty\end{aligned} \tag{5.7.917}$$

this is absurd and does not exist strictly speaking as the mean doesn't exists...!

The Cauchy distribution is used a lot in financial engineering as it is heavy tailed and therefore a very good candidate to be more accurate in predicting extreme values at the opposite to the Normal distribution that has the tails decreasing to quick. Further the Cauchy distribution is a heavy tailed law with a support on $\mathbb{R}$ when the Pareto distribution (also heavy tailed) is defined only on $\mathbb{R}^+$.

Software such as JASP and the R package BayesFactor (Morey et al., 12018) rely on the Cauchy distribution as a prior for many of the Bayesian analyses.

The Cauchy distribution if one of the most famous distribution function that... we cannot found in the spreadsheet softwares like Microsoft® Excel®. To be able to get the closed form of the inverse Cauchy CDF we start from the CDF proven previously:

$$P(X \leq x) = \frac{1}{\pi}\arctan(x) + \frac{1}{2} \tag{5.7.918}$$

and therefore if we let:

$$y = \frac{1}{\pi}\arctan(x) + \frac{1}{2} \tag{5.7.919}$$

We immediately get the inverse CDF:

$$x = \tan\left(\pi\left(y - \frac{1}{2}\right)\right) \tag{5.7.920}$$

That is useful in finance as we know (see section Numerical Methods page 6710) to simulate a Cauchy variable when we use the inverse transform sampling:

$$X = \tan\left(\pi\left(\mathcal{U}_{[0,1]} - \frac{1}{2}\right)\right) \tag{5.7.921}$$

Using the random variable transformation (see page 633) we immediately derive the "general Cauchy distribution" or simply named the "Cauchy distribution" and given by:

$$\boxed{f(x) = \frac{1}{b\pi\left[1 + \left(\dfrac{x-a}{b}\right)^2\right]} = \frac{1}{\pi b}\frac{b^2}{(x-a)^2 + b^2}} \tag{5.7.922}$$

In Bayesian inference the scale parameter b is often denoted ω and named the "width parameter".

By default, the Cauchy distribution in JASP and in the BayesFactor of the R software package is centred around zero. At first, this may seem counter-intuitive, because this is the prior parameter for the alternative hypothesis. The reason for the centring is that it allows us to test a non-directional hypothesis. Given that the prior distribution is symmetrical and centred around zero, effect sizes of, say, greater than $+0.5$ or smaller than -0.5 are equally likely. The bell-shape of the Cauchy distribution further indicates a belief that smaller effect sizes are more likely than larger effect sizes. When we increase the width parameter ω, we increase the a priori probability of large effect sizes (though small effect sizes will continue to be more likely).

5.7.6.16 Beta Distribution

Let us first recall that the Euler Gamma function is defined by the relation (see section Differential and Integral Calculus page 1574):

$$\Gamma(z)=\int\limits_0^{+\infty} e^{-x}x^{z-1}\mathrm{d}x \tag{5.7.923}$$

We proved (see section Differential and Integral Calculus page 1574) that a non-trivial property of this function is:

$$\Gamma(z+1)=z\Gamma(z) \tag{5.7.924}$$

Let us now write:

$$\Gamma(a)\Gamma(b)=\lim_{R\rightarrow+\infty}\iint\limits_{A_R} e^{-x-y}x^{a-1}y^{b-1}\mathrm{d}x\mathrm{d}y \tag{5.7.925}$$

where:

$$A_R=\{(x,y)|x\geq 0,y\geq 0,x+y\leq R\} \tag{5.7.926}$$

By the change of variables:

$$\begin{pmatrix}x\\y\end{pmatrix}=\begin{pmatrix}u-v\\v\end{pmatrix} \tag{5.7.927}$$

we get:

$$\Gamma(a)\Gamma(b)=\lim_{R\rightarrow+\infty}\iint\limits_{A_R} e^{-x-y}x^{a-1}y^{b-1}\mathrm{d}x\mathrm{d}y=\lim_{R\rightarrow+\infty}\int\limits_0^R e^{-u}\left(\int\limits_0^u (u-v)^{a-1}v^{b-1}\mathrm{d}v\right)\mathrm{d}u \tag{5.7.928}$$

For the internal integral we now use the substitution $v=ut, 0\leq t\leq 1$ and therefore we find:

$$\begin{aligned}\Gamma(a)\Gamma(b)&=\lim_{R\rightarrow+\infty}\int\limits_0^R e^{-u}\left(\int\limits_0^u (u-v)^{a-1}v^{b-1}\mathrm{d}v\right)\mathrm{d}u\\&=\lim_{R\rightarrow+\infty}\int\limits_0^R e^{-u}u^{a+b-1}\mathrm{d}u\int\limits_0^1(1-t)^{a-1}t^{b-1}\mathrm{d}t\overset{\text{def}}{=}B(a,b)\int\limits_0^{+\infty}e^{-u}u^{a+b-1}\mathrm{d}u\\&=B(a,b)\Gamma(a+b)\end{aligned} \tag{5.7.929}$$

Remark

For information, the beta function appears in Quantum Electrodynamics (QED) when calculating the one-loop Feynamn diagram for the regulation of the gauge boson self energy.

The function B that appears in the expression above is named "beta function[38]" and therefore we have:

$$\boxed{B(a,b)=B(b,a)=\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}} \tag{5.7.930}$$

Now that we have defined what we name the "beta function", consider the two parameters $a>0,b>0$ and consider also the special relation below as the "beta distribution" or "beta law" (there are several formulations of the beta distribution and a very important one is studied in detail in the section of Quantitative Management page 8074):

$$\boxed{P_{a,b}(x)=\frac{x^{a-1}(1-x)^{b-1}}{B(a,b)}1_{]0,1[}} \tag{5.7.931}$$

where:

$$\boxed{B(a,b)=\int\limits_0^1 x^{a-1}(1-x)^{b-1}\mathrm{d}x} \tag{5.7.932}$$

We will also encounter this latter function in the context of Quantum Field Theory!

Historically, this function comes from Bayesian statistics (notably a special case treated by Laplace) of the ratio of the Binomial distribution to the sum of all possible outcomes of this same Binomial distribution such that:

$$P(x\mid p,q)=\frac{C_{p+q}^{p}x^p(1-x)^q}{\int C_{p+q}^{p}y^p(1-y)^q\mathrm{d}y}=\frac{x^p(1-x)^q}{\int y^p(1-y)^q\mathrm{d}y} \tag{5.7.933}$$

Remark

The integral rewritten as following:

$$B(a+1,b+1)=\int\limits_0^1 x^a(1-x)^b\mathrm{d}x \tag{5.7.934}$$

is named the "Chebyshev integral".

The integral generalized as following:

$$B(x,a,b)=\int\limits_0^x t^{a-1}(1-t)^{b-1}\mathrm{d}t \tag{5.7.935}$$

is named the "incomplete beta function". While best known for its applications in Statistics, it is also widely used in many other fields such as actuarial science, economics, finance, survival analysis, life testing and telecommunications.

---

[38] Historically this function comes from the calculation of $m!n!=\lim_{a^2\rightarrow+\infty}\int\limits_0^{a^2} e^{-u}u^m\mathrm{d}u\int\limits_0^{a^2} e^{-v}v^n\mathrm{d}v$, using the Euler-Gamma function and that leads to $B(m+1,n+1)\equiv 2\int_0^{\pi/2}\cos^{2m+1}(\theta)\sin^{2n+1}(\theta)\mathrm{d}\theta=\frac{m!n!}{(m+n+1)!}$.

We first check that $P_{a,b}(x)$ that is effectively a distribution function (without getting into too much details ...):

$$\begin{aligned}\int\limits_{-\infty}^{+\infty} P_{a,b}(x)x &= \int\limits_{-\infty}^{+\infty} \frac{x^{a-1}(1-x)^{b-1}}{B(a,b)}\cdot 1_{]0,1[}\mathrm{d}x = \int\limits_{-\infty}^{+\infty} \frac{x^{a-1}(1-x)^{b-1}}{B(a,b)}\cdot 1_{]0,1[}\mathrm{d}x \\ &= \frac{1}{B(a,b)}\int\limits_{0}^{1} x^{a-1}(1-x)^{b-1}\mathrm{d}x = \frac{B(a,b)}{B(a,b)} = 1\end{aligned} \tag{5.7.936}$$

Let us now calculate the expected mean:

$$\begin{aligned}\mu &= \int\limits_{-\infty}^{+\infty} xP_{a,b}(x)\mathrm{d}x = \frac{1}{B(a,b)}\int\limits_{0}^{1} x^{a}(1-x)^{b-1}\mathrm{d}x \\ &= \frac{B(a+1,b)}{B(a,b)} = \frac{\Gamma(a+1)\Gamma(b)}{\Gamma(a+b+1)}\cdot\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} = \frac{a}{a+b}\end{aligned} \tag{5.7.937}$$

by using the relation:

$$\Gamma(z+1) = z\Gamma(z) \tag{5.7.938}$$

and its variance:

$$\begin{aligned}\sigma^2 &= \int\limits_{-\infty}^{+\infty} (x-\mu)^2 f(x)\mathrm{d}x = \frac{1}{B(a,b)}\int\limits_{0}^{1} (x-\mu)^2 x^{a-1}(1-x)^{b-1}\mathrm{d}x \\ &= \frac{1}{B(a,b)}\left(\int\limits_{0}^{1} x^{a+1}(1-x)^{b-1}\mathrm{d}x - 2\mu\int\limits_{0}^{1} x^{a}(1-x)^{b-1}\mathrm{d}x + \mu^2\int\limits_{0}^{1} x^{a-1}(1-x)^{b-1}\mathrm{d}x\right) \\ &= \frac{B(a+2,b)-2\mu^2 B(a,b)+\mu^2 B(a+1,b)}{B(a,b)} = \frac{B(a+2,b)-\mu^2 B(a,b)}{B(a,b)}\end{aligned} \tag{5.7.939}$$

As we know that:

$$\Gamma(z+1) = z\Gamma(z) \quad \text{and} \quad B(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} \tag{5.7.940}$$

we find:

$$B(a+2,b) = \frac{\mu\cdot(a+1)}{a+b+1} \tag{5.7.941}$$

and therefore:

$$\sigma^2 = \frac{\mu\cdot(a+1)}{a+b+1} - \mu^2 = \frac{ab}{(a+b)^2(a+b+1)} \tag{5.7.942}$$

Examples of plots of the beta distribution function for $(a,b) = (0.1,0.5)$ in red, $(a,b) = (0.3,0.5)$ in green, $(a,b) = (0.5,0.5)$ in black, $(a,b) = (0.8,0.8)$ in blue, $(a,b) = (1,1)$

in magenta, $(a,b)=(1,1.5)$ in cyan, $(a,b)=(1,2)$ in gray, $(a,b)=(1.5,2)$ in turquoise, $(a,b)=(2,2)$ in yellow,$(a,b)=(3,3)$ in gold color:

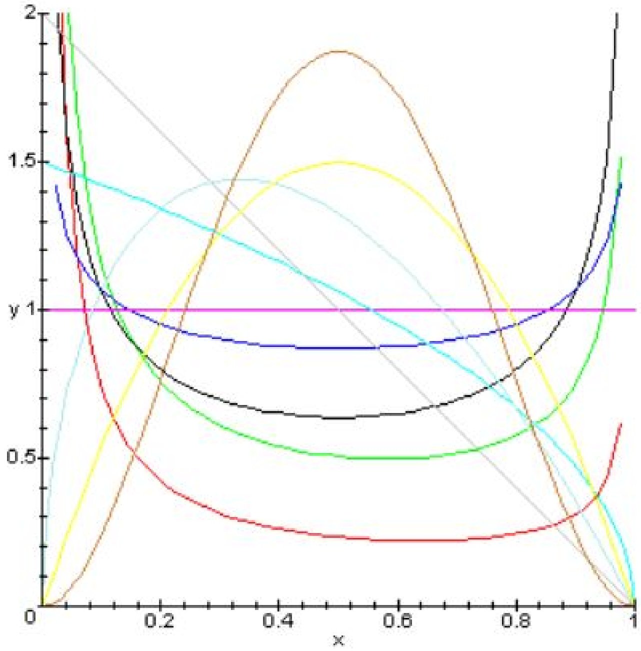

Figure 5.145: **Some Beta law mass functions**

Here is a plot example of the beta distribution and cumulative distribution for the parameters $(a,b)=(2,3)$:

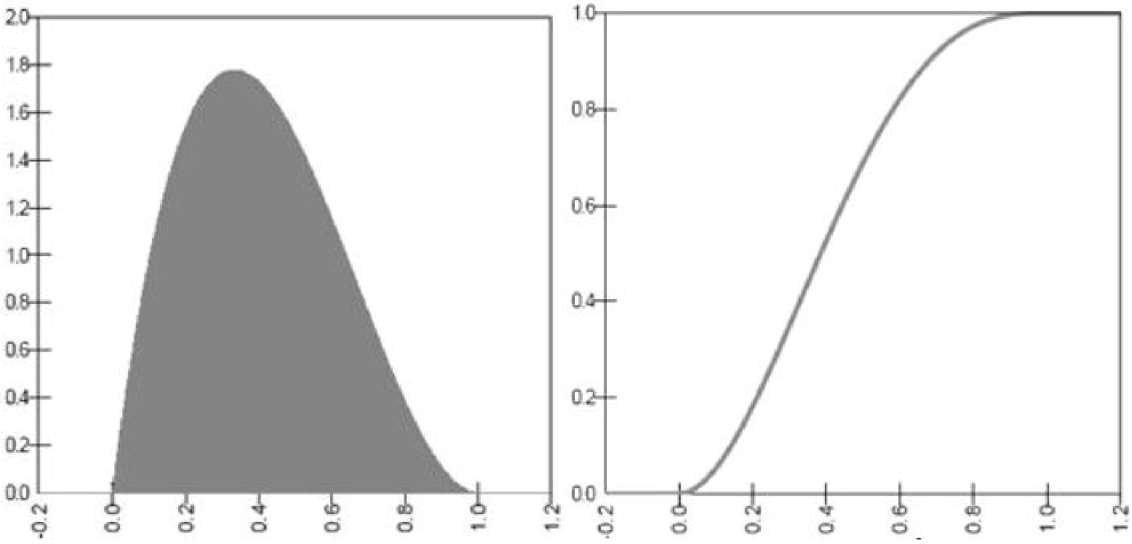

Figure 5.146: **Beta law (mass and cumulative distribution function)**

The fact that the beta law is one of the rare distribution functions whose support is between $]0,1[$ explains its frequent use in Bayesian statistics as an a priori law of the distribution of a proportion!

Remark

Notice the important special case that when $a, b = 1$, the beta distribution, reduce to a uniform continuous distribution! Indeed:

$$P_{a,b} = P_{1,1} = \frac{\Gamma(2)}{\Gamma(1)\Gamma(1)} p^{1-1}(1-p)^{1-1} 1_{]0,1[} = 1 \cdot 1_{]0,1[} \tag{5.7.943}$$

In general, if you want a beta prior distribution with parameters a and b but you only know μ and σ^2, they can be found via the both relations:

$$\begin{aligned} \mu &= \frac{a}{a+b} \\ \sigma^2 &= \frac{ab}{(a+b)^2(a+b+1)} \end{aligned} \tag{5.7.944}$$

We can solve the first one as follows for b:

$$b = \frac{a(1-\mu)}{\mu} \tag{5.7.945}$$

Substituting that latter into the above σ^2 yields:

$$\begin{aligned} \sigma^2 = \frac{a^2(1-\mu)}{\mu(a+b)^2(a+b+1)} &= \frac{a^2(1-\mu)}{\mu(a[1+(1-\mu)/\mu])^2(a+a(1-\mu)/\mu+1)} \\ &= \frac{(1-\mu)}{\mu(1+(1-\mu)/\mu)^2(a/\mu+1)} \end{aligned} \tag{5.7.946}$$

Rearranging that latter yields:

$$a = \frac{1-\mu-\sigma^2\mu^3}{\sigma^2\mu^2} \tag{5.7.947}$$

and therefore:

$$b = \frac{(1-\mu)\left[1-\mu-\sigma^2\mu^3\right]}{\sigma^2\mu^3} \tag{5.7.948}$$

5.7.6.16.1 Regularized Incomplete beta function integral

What follows should better be placed in the section of Functional Analysis however it has seem more pedagogical to us to place it just here for obvious reasons.

Consider the "regularized incomplete Beta function $I_x(a,b)$" (or "regularized beta function" for short) defined in terms of the incomplete beta function and the complete beta function as (for $\alpha > 0$):

$$\boxed{I_x(a,b) = \frac{B(x,a,b)}{B(a,b)} = \frac{\displaystyle\int_0^x t^{a-1}(1-t)^{b-1}\,\mathrm{d}t}{\displaystyle\int_0^1 t^{a-1}(1-t)^{b-1}\,\mathrm{d}t}} \tag{5.7.949}$$

where for recall $a > 0$ and $b > 0$. This function will be useful to us in some Bayesian A/B statistics (see section Statistics page 996) but also in String Theory (see section String Theory page 6099)!

Notice the canonical values that are immediate:

$$I_0(a,b)=0 \qquad I_1(a,b)=0 \tag{5.7.950}$$

We want to prove the recursive property:

$$I_x(a+1,b)=I_x(a,b)-\frac{x^a\,(1-x)^b}{a\,B\,(a,b)} \tag{5.7.951}$$

Remark

This also means that:

$$I_x(a-1,b)=I_x(a,b)-\frac{x^{a-1}\,(1-x)^b}{(a-1)B\,(a-1,b)} \tag{5.7.952}$$

but for $a>1$ (and still $b>0$).

Proof 5.47.6. Using the following Beta function (see page 761) property:

$$B(a+1,b)=\frac{a!(b-1)!}{(a+b)!}=\frac{(a-1)!(b-1)!}{(a+b-1)!}\frac{a}{a+b}=\frac{aB(a,b)}{a+b} \tag{5.7.953}$$

Remark

From the above relation and because of symmetry of the beta function, the following three results follow almost immediately:

$$\begin{aligned}B(a,b+1)&=\frac{bB(a,b)}{a+b}\\ B(a+1,b)+B(a,b+1)&=B(a,b)\\ B(a+1,b-1)&=\frac{aB(a,b)}{b-1}\end{aligned} \tag{5.7.954}$$

We compute the derivative:

$$I'_x(a+1,b)=\frac{\mathrm{d}I_x(a+1,b)}{\mathrm{d}t}=\frac{x^a(1-x)^{b-1}}{B(a+1,b)}=\frac{x^a(1-x)^{b-1}}{B(a,b)a/(b+a)}=(a+b)\frac{x^a(1-x)^{b-1}}{B(a,b)a} \tag{5.7.955}$$

Now let:

$$f(a,b,x)=I_x(a+1,b)-I_x(a,b)+\frac{x^a\,(1-x)^b}{a\,B\,(a,b)} \tag{5.7.956}$$

Then $f(a,b,0)=0$ and:

$$\begin{aligned}
f'(a,b,x) &= I'_x(a+1,b)-I'_x(a,b)+\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{x^a\,(1-x)^b}{a\,B\,(a,b)}\right)\\
&=(a+b)\frac{x^a(1-x)^{b-1}}{B(a,b)a}-\frac{x^{a-1}(1-x)^{b-1}}{B(a,b)}+\frac{x^{a-1}(1-x)^b}{B(a,b)}-\frac{bx^a(1-x)^{b-1}}{aB(a,b)}\\
&=\frac{x^{a-1}(1-x)^{b-1}}{B(a,b)}\left(\frac{(a+b)x}{a}-1+1-x-\frac{bx}{a}\right)=0
\end{aligned}\tag{5.7.957}$$

therefore $f\equiv 0$ and the recursive property is proven.

■ Q.E.D.

So we have proved that:

$$I_x(a-1,b)=I_x(a,b)-\frac{x^{a-1}\,(1-x)^b}{(a-1)B\,(a-1,b)}\tag{5.7.958}$$

And notice that we have the limit case:

$$I_x(1,b)=\frac{\displaystyle\int\limits_0^x t^0\,(1-t)^{b-1}\,\mathrm{d}t}{\displaystyle\int\limits_0^1 t^0\,(1-t)^{b-1}\,\mathrm{d}t}=\frac{-\left.\dfrac{(1-t)^b}{b}\right|_0^x}{-\left.\dfrac{(1-t)^b}{b}\right|_0^1}=\frac{-\dfrac{(1-x)^b}{b}+\dfrac{1}{b}}{\dfrac{1}{b}}=1-(1-x)^b\tag{5.7.959}$$

So now recursively iterating:

$$I_x(a-1,b)=I_x(a,b)-\frac{x^{a-1}\,(1-x)^b}{(a-1)B\,(a-1,b)}\tag{5.7.960}$$

Until the case:

$$I_x(1,b)=1-(1-x)^b\tag{5.7.961}$$

$$I_x(a,b)=1-(1-x)^b-\sum_{j=1}^{a-1}\frac{x^{a-j}(1-x)^b}{(a-j)B(a-j,b)}\tag{5.7.962}$$

Subsuming the zeroth term into the sum:

$$I_x(a,b)=1-\sum_{i=0}^{a-1}\frac{x^i(1-x)^b}{(b+i)B(1+i,b)}\tag{5.7.963}$$

And we will stop here for the study of this function as this is all what we need in the actual state of this textbook for practical applications!

5.7.6.17 Gamma Distribution

The Euler Gamma function being known, consider two parameters $a > 0, \lambda > 0$ and let us define the "Gamma distribution" (or "Gamma law") as given by the relation (density function):

$$\boxed{P_{a,\lambda}(x) = \frac{x^{a-1}e^{-\lambda x}}{\int\limits_{0}^{+\infty} x^{a-1}e^{-\lambda x}\mathrm{d}x} \cdot 1_{]0,+\infty[}} \tag{5.7.964}$$

By the change of variables $t = \lambda x$ we obtain:

$$\int\limits_{0}^{+\infty} x^{a-1}e^{-\lambda x}\mathrm{d}x = \frac{\Gamma(a)}{\lambda^a} \tag{5.7.965}$$

and we can then write the relation in a more conventional form that we find frequently in the literature:

$$\boxed{P_{a,\lambda}(x) = \frac{x^{a-1}e^{-\lambda x}}{\Gamma(a)}\lambda^a \cdot 1_{]0,+\infty[}} \tag{5.7.966}$$

and it is under this notation that we find this distribution function in Microsoft® Excel® 11.8346 under the name `GAMMADIST( )` and its inverse by `GAMMAINV( )`. Notice that the previous relation is also often denoted:

$$\Gamma(a,\lambda) = \frac{x^{a-1}e^{-\lambda x}}{\Gamma(a)}\lambda^a \cdot 1_{]0,+\infty[} \tag{5.7.967}$$

Let us now see a simple property of the Gamma distribution that will be partially useful for the study of the Welch statistical test (see page 1020). First recall that we have shown above that:

$$\forall y \in \mathbb{R} \quad f_Y(y) = \frac{1}{c^{te}} f_X\left(\frac{y}{c^{te}}\right) \tag{5.7.968}$$

Let us write $Y = c^{te}X$, then we have immediately:

$$f_Y(y) = \frac{y^{a-1}e^{\lambda \frac{y}{c^{te}}}}{\Gamma(a)}\left(\frac{\lambda}{c^{te}}\right) 1_{]0,+\infty[} \tag{5.7.969}$$

So the multiplication by a constant of random variable that follows a Gamma distribution has only for effect of dividing the parameter λ by the same constant. This is the reason why λ is named "scale parameter".

If $a \in \mathbb{N}$, the Gamma distribution at the denominator becomes (see section Differential and Integral Calculus page 1574) the factorial $(a-1)!$. The Gamma function can then be written:

$$P_{a,\lambda} = \frac{x^{a-1}\lambda^a e^{-\lambda x}}{(a-1)!} = \frac{(x\lambda)^{a-1}}{(a-1)!}\lambda e^{-\lambda x} \tag{5.7.970}$$

This particular notation of the Gamma distribution is named the "Erlang distribution" that we find naturally in the theory of queues and that is very important in practice!

Remark

If $a = 1$ then $\Gamma(a) = 1$ and $x^{a-1} = 1$ and we fall back on the exponential distribution.

Then we check with a similar reasoning to this of the beta distribution that $P_{a,\lambda}(x)$ is a distribution function:

$$\int\limits_{-\infty}^{+\infty} P_{a,\lambda} \mathrm{d}x = 1 \tag{5.7.971}$$

Examples of plots of the beta distribution function for $(a, \lambda) = (0.5, 1)$ in red, $(a, \lambda) = (1, 1)$ in green, $(a, \lambda) = (2, 1)$ in black, $(a, \lambda) = (4, 2)$ in blue, $(a, \lambda) = (16, 8)$ in magenta:

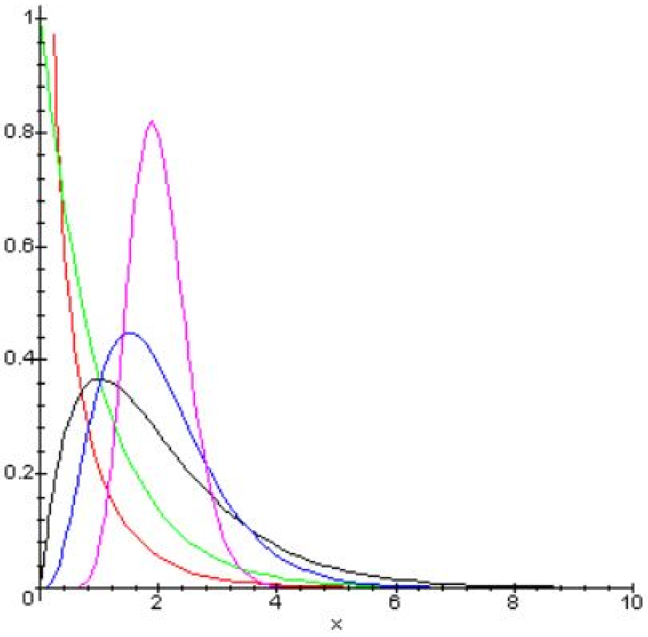

Figure 5.147: **Some Gamma law mass functions**

and a plot example of the Gamma distribution and cumulative distribution for the parameters $(a, \gamma) = (4, 1)$:

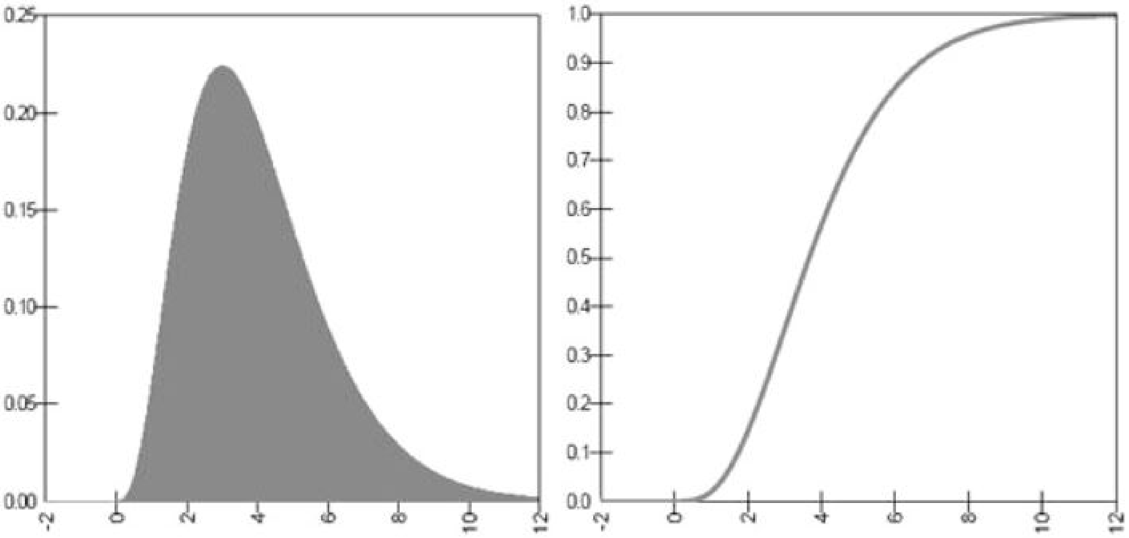

Figure 5.148: Gamma law (mass and cumulative distribution function)

Let X be a positive random variable following a Gamma distribution:

$$X \sim \text{Gam}(a,b) \tag{5.7.972}$$

Then, the cumulative distribution function of X is:

$$F_X(x)=\frac{\gamma(a,bx)}{\Gamma(a)} \tag{5.7.973}$$

Indeed, the probability density function of the Gamma distribution is for reminder:

$$f_X(x)=\frac{b^a}{\Gamma(a)}x^{a-1}\exp[-bx] \tag{5.7.974}$$

Thus, the cumulative distribution function is:

$$\begin{aligned}F_X(x)&=\int\limits_0^x \text{Gam}(z;a,b)\mathrm{d}z\\&=\int\limits_0^x \frac{b^a}{\Gamma(a)}z^{a-1}\exp[-bz]\mathrm{d}z\\&=\frac{b^a}{\Gamma(a)}\int\limits_0^x z^{a-1}\exp[-bz]\mathrm{d}z\end{aligned} \tag{5.7.975}$$

Substituting $t=bz$, i.e. $z=t/b$, this becomes:

$$\begin{aligned}F_X(x)&=\frac{b^a}{\Gamma(a)}\int\limits_{b\cdot 0}^{b\cdot x}\left(\frac{t}{b}\right)^{a-1}\exp\left[-b\left(\frac{t}{b}\right)\right]\mathrm{d}\left(\frac{t}{b}\right)\\&=\frac{b^a}{\Gamma(a)}\cdot\frac{1}{b^{a-1}}\cdot\frac{1}{b}\int\limits_0^{bx} t^{a-1}\exp[-t]\mathrm{d}t\\&=\frac{1}{\Gamma(a)}\int\limits_0^{b\cdot x} t^{a-1}\exp[-t]\mathrm{d}t\end{aligned} \tag{5.7.976}$$

With the definition of the "lower incomplete gamma function":

$$\gamma(s,x)=\int_0^x t^{s-1}\exp[-t]\mathrm{d}t \tag{5.7.977}$$

we arrive at the final result given earlier above:

$$F_X(x)=\frac{\gamma(a,bx)}{\Gamma(a)} \tag{5.7.978}$$

The Gamma function has also for expected mean:

$$\mu=\int\limits_{-\infty}^{+\infty} xf(x)\mathrm{d}x=\frac{\lambda^a}{\Gamma(a)}\int\limits_{-\infty}^{+\infty} x^a e^{-\lambda x}\mathrm{d}x=\frac{\lambda^a}{\Gamma(a)}\frac{\Gamma(a+1)}{\lambda^{a+1}}\frac{\lambda^a}{\Gamma(a)}\frac{a\Gamma(a)}{\lambda^{a+1}}=\frac{a}{\lambda} \tag{5.7.979}$$

and for variance:

$$\begin{aligned}\sigma^2&=\int\limits_{-\infty}^{+\infty}(x-\mu)^2 f(x)\mathrm{d}x=\frac{\lambda^a}{\Gamma(a)}\int\limits_{-\infty}^{+\infty}(x-\mu)^2x^{a-1}e^{-\lambda x}\mathrm{d}x\\&=\frac{\lambda^a}{\Gamma(a)}\left(\int\limits_{-\infty}^{+\infty}x^{a+1}e^{-\lambda x}x-2\mu\int\limits_{-\infty}^{+\infty}x^a e^{-\lambda x}x+\mu^2\int\limits_{-\infty}^{+\infty}x^{a-1}e^{-\lambda x}\mathrm{d}x\right)\\&=\frac{\lambda^a}{\Gamma(a)}\left(\frac{\Gamma(a+2)}{\lambda^{a+2}}+\mu^2\frac{\Gamma(a)}{\lambda^a}-2\mu\frac{\Gamma(a+1)}{\lambda^{a+1}}\right)\\&=\frac{1}{\lambda^2\Gamma(a)}\left(\Gamma(a+2)+a^2\Gamma(a)-2a\Gamma(a+1)\right)\\&=\frac{1}{\lambda^2\Gamma(a)}\left((a+1)a\Gamma(a)+a^2\Gamma(a)-2a^2\Gamma(a)\right)=\frac{a}{\lambda^2}\end{aligned} \tag{5.7.980}$$

Let us now prove a property of the Gamma distribution that will permit us later in this chapter, during our study of the analysis of variance and confidence intervals based on small samples, another extremely important property of the Chi-square distribution.

As we know, the distribution function of a random variable following a Gamma function of parameters $a,\lambda>0$ is:

$$P_{a,\gamma}(x)=f(x)=\frac{e^{-\lambda x}x^{a-1}}{\Gamma(a)}\lambda^a 1_{[0,+\infty]} \tag{5.7.981}$$

with (see section Differential and Integral Calculus page 1574) the Euler Gamma function:

$$\Gamma(a)=\int\limits_0^{+\infty} e^{-x}x^{a-1}\mathrm{d}x \tag{5.7.982}$$

Moreover, when a random variable follows a Gamma function we often notice it in the following way:

$$X=\gamma(a,\lambda) \tag{5.7.983}$$

Let X, Y be two independent variables. We will prove that if $X = \gamma(p, \lambda)$ and $Y = \gamma(q, \lambda)$, hence with the same scale parameter, then:

$$X + Y = \gamma(p + q, \lambda) \tag{5.7.984}$$

We write f the density function of the pair $X, Y, f(x)$ the density function of X and f_Y the density function of Y. Because X and Y are independent, we have:

$$f(x, y) = f_X(x) \cdot f_Y(y) \tag{5.7.985}$$

for all $x, y > 0$.

Let $Z = X + Y$. The distribution function of Z is therefore:

$$F(z) = P(Z \leqslant z) = P(X + Y \leqslant z) = \iint\limits_D f(x, y)\mathrm{d}x\mathrm{d}y \tag{5.7.986}$$

where $D = \{(x, y)|x + y \leq z\}$.

Remark

As we already know we name such a calculation a "convolution" and statisticians often have to handle such entities because they work on many random variables that they have to sum or even to multiply.

Simplifying:

$$F(z) = \int\limits_{-\infty}^{+\infty} \int\limits_{-\infty}^{z-x} f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y \tag{5.7.987}$$

We perform the following change of variable $x = x, y = s - x$. The Jacobian is therefore (see section Differential and Integral Calculus page 1524):

$$J = \begin{vmatrix} \dfrac{\partial x}{\partial x} & \dfrac{\partial x}{\partial s} \\ \dfrac{\partial y}{\partial x} & \dfrac{\partial y}{\partial s} \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ -1 & 0 \end{vmatrix} = 1 \tag{5.7.988}$$

Therefore with the new integration limits $s = x + y = x + (z - x) = z$ we have:

$$F(z) = \int\limits_{-\infty}^{+\infty} \int\limits_{-\infty}^{z} f_X(x)f_Y(s - x)\mathrm{d}s\mathrm{d}x = \int\limits_{-\infty}^{z} \int\limits_{-\infty}^{+\infty} f_X(x)f_Y(s - x)\mathrm{d}x\mathrm{d}s \tag{5.7.989}$$

If we denote by g the density function Z we have:

$$F(z) = \int\limits_{-\infty}^{z} \int\limits_{-\infty}^{+\infty} f_X(x)f_Y(s - x)\mathrm{d}x\mathrm{d}s = \int\limits_{-\infty}^{z} g(s)\mathrm{d}s \tag{5.7.990}$$

Then it follows:

$$g(s) = \int\limits_{-\infty}^{+\infty} f_X(x)f_Y(s - x)\mathrm{d}x \tag{5.7.991}$$

f_X and f_Y being null when the argument is negative, we can change the limits of integration:

$$g(s)=\int_0^s f_X(x)f_Y(s-x)\mathrm{d}x \quad \text{for} \quad s\geqslant 0 \tag{5.7.992}$$

Let us calculate g:

$$g(s)=\dfrac{\lambda^{p+q}e^{-\lambda s}}{\Gamma(p)\Gamma(q)}\int_0^s x^{p-1}(s-x)^{q-1}\mathrm{d}x \tag{5.7.993}$$

After the change of variable $x=st$ we obtain:

$$g(s)=\dfrac{\lambda^{p+q}e^{-\lambda s}}{\Gamma(p)\Gamma(q)}s^{p+q-1}\int_0^1 t^{p-1}(1-t)^{q-1}\mathrm{d}t=\dfrac{\lambda^{p+q}e^{-\lambda s}}{\Gamma(p)\Gamma(q)}s^{p+q-1}B(p,q) \tag{5.7.994}$$

where B is the beta function we saw earlier in our study of the beta distribution. But we have also proved the relation:

$$B(p,q)=\dfrac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)} \tag{5.7.995}$$

Therefore:

$$B(p,q)=\dfrac{\lambda^{p+q}e^{-\lambda s}}{\Gamma(p+q)}s^{p+q-1} \tag{5.7.996}$$

More explicitly:

$$g(x,y)=\dfrac{\lambda^{p+q}e^{-\lambda(x+y)}}{\Gamma(p+q)}(x+y)^{p+q-1} \tag{5.7.997}$$

Which finally gives us:

$$P(Z\leqslant z)=P(X+Y\leqslant z)=\int_0^s g(s)\mathrm{d}s=\int_0^s\dfrac{\lambda^{p+q}e^{-\lambda s}}{\Gamma(p+q)}s^{p+q-1}\mathrm{d}s \tag{5.7.998}$$

This shows that if two random variables follow a Gamma distribution then their sum will also follow a Gamma distribution with parameters:

$$X+Y=\gamma(p+q,\lambda) \tag{5.7.999}$$

So the Gamma distribution is stable by addition as are all distribution arising from the Gamma distribution that we will see below.

5.7.6.17.1 Generalized Gamma Distribution

The generalized gamma distribution is a continuous probability distribution with three parameters. It is a generalization of the two-parameter gamma distribution. Since many distributions commonly used for parametric models in survival analysis (such as the exponential distribution, the Weibull distribution and the Gamma distribution, and log-normal) are special cases of the generalized gamma, it is sometimes used to determine which parametric model is appropriate for a given set of data.

Therefore let us notice that if we write after trials and errors the following density function named "generalized Gamma law":

$$\boxed{f(x)=\frac{\eta}{\alpha\Gamma(\kappa)}\left(\frac{x}{\alpha}\right)^{\kappa\eta-1}e^{-\left(\frac{x}{\alpha}\right)^{\eta}}} \tag{5.7.1000}$$

with $x>0$, $\alpha>0$, $\eta>0$, $\kappa>0$.

Then, for $\kappa=1$ we fall back on the density function of the Weibull distribution (see section Industrial Engineering page 8736) that is with our own notations of the corresponding section is given by:

$$f(x)=\frac{\alpha}{\beta}\frac{x^{\alpha-1}}{\beta^{\alpha-1}}e^{-\frac{x^\alpha}{\beta^\alpha}}=\frac{\alpha}{\beta^\alpha}x^{\alpha-1}e^{-\left(\frac{\alpha}{\beta}\right)^\alpha} \tag{5.7.1001}$$

For $\eta=1$, we fall back the Gamma density function just introduced before:

$$f(x)=\frac{x^{a-1}e^{-\lambda x}}{\Gamma(a)}\lambda^a\cdot 1_{]0,+\infty[} \tag{5.7.1002}$$

For $\kappa=1$ and $\eta=1$, we fall back on the exponential distribution also seen previously:

$$f(x)=\lambda e^{\lambda x}\cdot 1_{[0,+\infty[} \tag{5.7.1003}$$

and finally for $\eta\rightarrow 0$, $\kappa\rightarrow+\infty$ we fall back on a log-Normal distribution after developing the limits using the Stirling, Hospital and Taylor techniques (see section Numerical Methods page 6301, Differential and Integral Calculus page 1461, Sequences and Series page 1696):

$$f(x)=\frac{1}{\sigma x\sqrt{2\pi}}e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}} \tag{5.7.1004}$$

As always, on request we can detail the developments!

5.7.6.18 Chi-Square (Pearson) Distribution

The "chi-square distribution" (also named "chi-square law" or "Pearson law") has a very important place in the industrial practice for some common hypothesis tests (see far below...) and is by definition only a particular case of the Gamma distribution in the case where $a=k/2$ and $\lambda=1/2$, when k is a positive integer:

$$\boxed{P_k(x)=\frac{1}{2^{\frac{k}{2}}\Gamma(k/2)}x^{\frac{k}{2}-1}e^{-\frac{x}{2}}\cdot 1_{[0,+\infty[}} \tag{5.7.1005}$$

Remark

We will also prove later during our study of the confidence interval on the variance with known mean (see page 857), the very important property that if X follows a Normal standard distribution $\mathcal{N}(0,1)$ then $X^2=\chi_1^2$.

This relation that connects the chi-square distribution with the Gamma distribution is important in the in Microsoft® Excel® 11.8346 as the function `CHIDIST( )` returns the confidence level and not the distribution function. Then you must use the function `GAMMADIST()` with the parameters given above (except that you must take the inverse of $1/2$: also 2 as parameter) to get the distribution and cumulative functions.

The reader who wishes to check that the Chi-square distribution is only a special case of the Gamma distribution can write in Microsoft® Excel® 14.0.6123:

```
=CHISQ.DIST(2*x,2*k,TRUE)
=GAMMA.DIST(x,k,1,TRUE)
```

All calculations made previously still apply and we get immediately:

$$\mu=k,\sigma^2=2k \tag{5.7.1006}$$

Examples of plots of the chi-squared distribution function for $k=1$ in red, $k=3$ in green, in black, $k=4$ in blue:

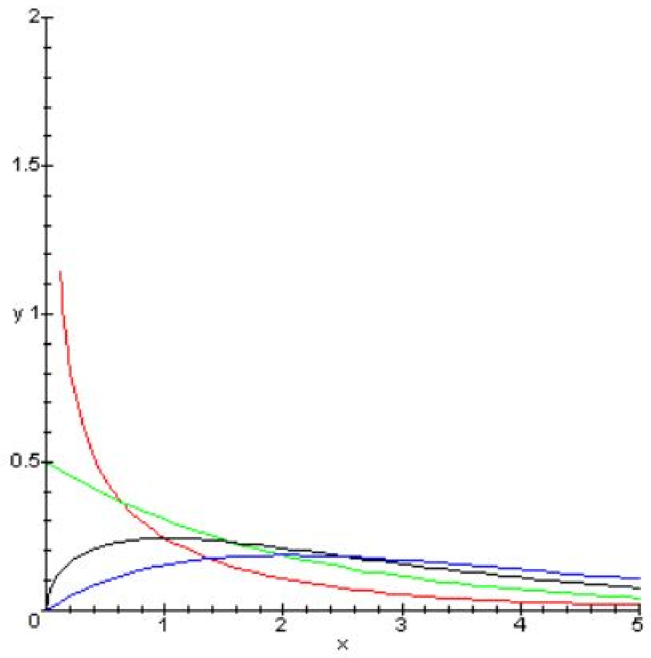

Figure 5.149: **Some χ^2 law mass functions**

and a plot example of the chi-squared distribution and cumulative distribution for the parameter $k=2$ (for more plots about this distribution see further below on page 388):

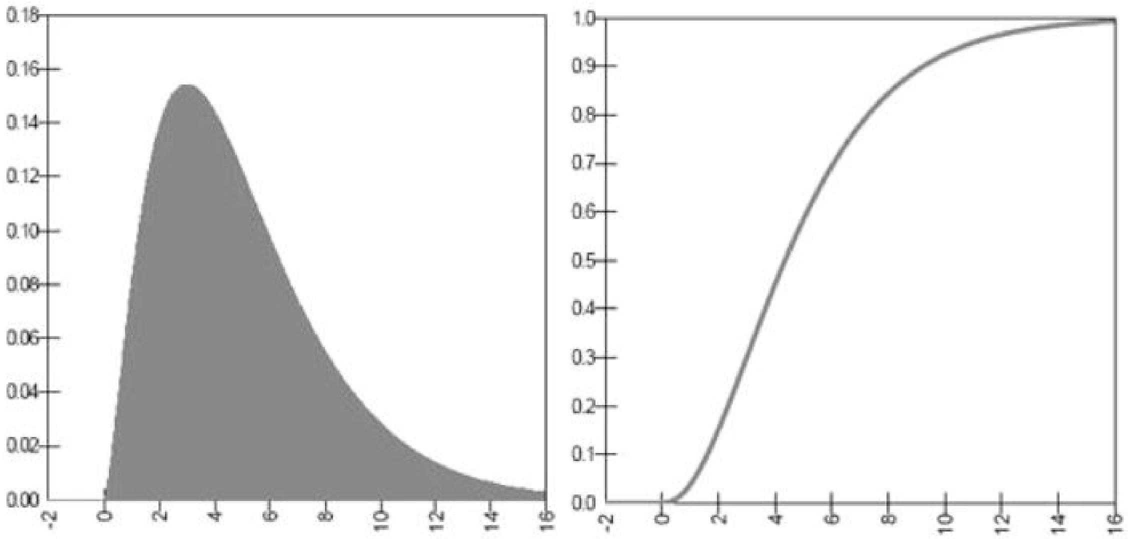

Figure 5.150: χ^2 **law (mass and cumulative distribution function)**

In the literature, it is traditional to write:

$$X=\chi_k^2 \quad \text{or} \quad X=\chi^2(k) \tag{5.7.1007}$$

to indicate that the distribution of the random variable X is a chi-square distribution. Furthermore it is common to name the parameter k "degrees of freedom" and abbreviate it "df".

The χ^2 distribution is therefore a special case of the Gamma distribution and by taking $k=2$ we also find the exponential distribution (see above) for $\lambda=1/2$:

$$P_2(x)=\frac{1}{2^1\Gamma(1)}x^{2/2-1}e^{-x/2}\cdot 1_{[0,+\infty[}=\frac{1}{2}e^{-\frac{x}{2}}1_{[0,+\infty[} \tag{5.7.1008}$$

Moreover, since (see section Differential and Integral Calculus page 1574):

$$\Gamma\left(\frac{1}{2}\right)=\sqrt{\pi} \tag{5.7.1009}$$

the χ^2 distribution with k equal to unity can be written as:

$$P_1(x)=\frac{1}{2^{1/2}\Gamma(1/2)}x^{1/2-1}e^{-x/2}\cdot 1_{[0,+\infty[}=\frac{1}{\sqrt{2\pi x}}e^{-x/2}\cdot 1_{[0,+\infty[} \tag{5.7.1010}$$

Finally, let us finish with a fairly large property in the field of statistical tests that we will investigate a little further and particularly for confidence intervals of rare events and the famous Fisher method for multiple p-value null hypothesis tests (see page 948). Indeed, the reader can check in a spreadsheet software like Microsoft® Excel® 14.0.6123 that we have:

=POISSON.DIST($x\in\mathbb{N},\mu$,TRUE)
=1-CHISQ.DIST($2\mu,2(x+1)$,TRUE)
=1-GAMMA.DIST($2\mu,x+1$,TRUE)
=1-EXPON.DIST($x,0.5$,TRUE)

So we need to prove this relation between law χ^2 and Poisson distributions. See it starting from the Gamma distribution:

$$P_{a,\lambda}(x)=\frac{x^{a-1}e^{-\lambda x}}{\Gamma(a)}\lambda^a 1_{]0,+\infty[} \tag{5.7.1011}$$

If we write $\lambda=1/2$ and $a=k/2$ then we have the χ^2 distribution with k degrees of freedom:

$$P_k(x)=\frac{1}{2^{k/2}\Gamma(k/2)}x^{k/2-1}e^{-x/2}1_{]0,+\infty[} \tag{5.7.1012}$$

Now remember that we have seen in the section Sequences and Series (page 1703), the following Taylor (Maclaurin) series from order $n-1$ around 0 to λ with integral rest:

$$e^{\lambda}=\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}e^x(0)+\int_0^{\lambda}e^n(t)\frac{(\lambda-1)^{n-1}}{(n-1)!}\mathrm{d}t=\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}+\int_0^{\lambda}e^t\frac{(\lambda-1)^{n-1}}{(n-1)!}\mathrm{d}t \tag{5.7.1013}$$

$$\underset{u=\lambda-t}{=}\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}-\int_{\lambda}^{0}e^{\lambda-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u=\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}+\int_0^{\lambda}e^{\lambda-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u \tag{5.7.1014}$$

We multiply by $e^{-\lambda}$:

$$e^{\lambda}e^{-\lambda}=e^{-\lambda}\left(\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}+\int_0^{\lambda}e^{\lambda-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u\right)\Rightarrow 1=\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}e^{-\lambda}+\int_0^{\lambda}e^{-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u \tag{5.7.1015}$$

And therefore:

$$\sum_{k=0}^{n-1}\frac{\lambda^k}{k!}e^{-\lambda}=1-\int_0^{\lambda}e^{-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u \tag{5.7.1016}$$

Now, let us focus on the term:

$$\int_0^{\lambda}e^{-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u \tag{5.7.1017}$$

and make a first change of variable:

$$\int_0^{\lambda}e^{-u}\frac{u^{n-1}}{(n-1)!}\mathrm{d}u\underset{u=x/2}{=}\int_0^{\lambda}\frac{1}{2^{n-1}(n-1)!}x^{n-1}e^{-x/2}\frac{1}{2}\mathrm{d}x=\int_0^{\lambda}\frac{1}{2^n(n-1)!}x^{n-1}e^{-x/2}\mathrm{d}x \tag{5.7.1018}$$

and a second change of variable (caution! the k in the change of variable is not the same as this in the Poisson sum...):

$$\int_0^{\lambda}\frac{1}{2^n(n-1)!}x^{n-1}e^{-x/2}\mathrm{d}x\underset{n=k/2}{=}\int_0^{\lambda}\frac{1}{2^{k/2}\left(\dfrac{k}{2}-1\right)!}x^{k/2-1}e^{-x/2}\mathrm{d}x \tag{5.7.1019}$$

However, we have shown in the section of Differential and Integral Calculus (page 1574) that if x is a positive integer:

$$x! = \Gamma(x+1)! \tag{5.7.1020}$$

Then it comes:

$$\left(\frac{k}{2}-1\right)! = \Gamma\left(\left(\frac{k}{2}-1\right)+1\right) = \Gamma\left(\frac{k}{2}\right) \tag{5.7.1021}$$

Finally we have:

$$\int\limits_0^\lambda \frac{1}{2^{k/2}\left(\dfrac{k}{2}\right)!} x^{k/2-1} e^{-x/2} \mathrm{d}x \tag{5.7.1022}$$

where we find out the chi-squared distribution under the integral! So at the end:

$$\sum_{k=0}^{n-1} \frac{\lambda^k}{k!} e^{-\lambda} = 1 - \int\limits_0^\lambda \frac{1}{2^{k/2}\left(\dfrac{k}{2}\right)!} x^{k/2-1} e^{-x/2} \mathrm{d}x \tag{5.7.1023}$$

This explains the formulas given above for the spreadsheet software, remembering that we choose to write:

$$\begin{aligned} n &= \frac{k}{2} \Leftrightarrow k = 2n \\ u &= \frac{x}{x} \Leftrightarrow x = 2u = 2(\lambda - t)_{t=0} = 2\lambda \end{aligned} \tag{5.7.1024}$$

Finally for people that don't have an access to spreadsheet or statistical software:

CHI-SQUARED PERCENTAGE POINTS

k	0.1%	0.5%	1.0%	2.5%	5.0%	10.0%	12.5%	20.0%	25.0%	33.3%	50.0%

5.7.6.18.1 Noncentral chi-square distribution

The "noncentral chi-squared distribution" can be found in two major situation in industrial statistics (and hence in business):

- In the lower and upper bound estimations of tolerance interval for an univariate Normal distribution
- As the distribution of the alternative hypothesis (H_1) of many NHST tests and hence used to calculate the power of the corresponding tests.

Let us now determine the density probability function of the noncentered chi-square distribution.

We know that the density probability function of $X^2 = \mathcal{N}(0,1)^2$ follows by definition a χ^2 distribution of one degree of freedom. The question now is what distribution follows $\mathcal{N}(\lambda,1)^2$??

First we know that we can rewrite this as:

$$T = X - \lambda = \mathcal{N}(0,1) \tag{5.7.1025}$$

Hence T has distribution $\Phi(t)$ and density function (see earlier our study of the Normal distribution):

$$\phi(t) = \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} \tag{5.7.1026}$$

The distribution of X^2 is obviously:

$$\begin{aligned} P(X^2 \leq x) &= P\left(-\sqrt{x} \leq X \leq \sqrt{x}\right) \\ &= P\left(-\sqrt{x} - \lambda \leq X_1 - \lambda \leq \sqrt{x} - \lambda\right) \\ &= \Phi(\sqrt{x} - \lambda) - \Phi(-\sqrt{x} - \lambda) \end{aligned} \tag{5.7.1027}$$

Hence the density is:

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}\left[\Phi(\sqrt{x} - \lambda) - \Phi(-\sqrt{x} - \lambda)\right] &= \frac{1}{2\sqrt{x}}\left[\phi(\sqrt{x} - \lambda) + \phi(\sqrt{x} + \lambda)\right] \\ &= \frac{1}{2\sqrt{x}}\left[\frac{1}{\sqrt{2\pi}} e^{\frac{(\sqrt{x}-\lambda)^2}{2}} + \frac{1}{\sqrt{2\pi}} e^{\frac{(\sqrt{x}+\lambda)^2}{2}}\right] \\ &= \frac{1}{\sqrt{2\pi x}} e^{-\frac{1}{2}(x+\lambda^2)}\left[\frac{e^{\lambda\sqrt{x}} + e^{-\lambda\sqrt{x}}}{2}\right] \end{aligned} \tag{5.7.1028}$$

And we know (see section Sequences and Series page 1703) the following Maclaurin series:

$$e^x = \sum_{k=0}^{+\infty} \frac{1}{k!} x^k \tag{5.7.1029}$$

Hence:

$$\begin{aligned}\frac{1}{\sqrt{2\pi x}}e^{-\frac{1}{2}(x+\lambda^2)}\left[\frac{e^{\lambda\sqrt{x}}+e^{-\lambda\sqrt{x}}}{2}\right]&=\frac{1}{\sqrt{2\pi x}}e^{-\frac{1}{2}(x+\lambda^2)}\left[\sum_{k=0}^{+\infty}\frac{(\lambda\sqrt{x})^{2k}}{(2k)!}\right]\\&=\sum_{k=0}^{+\infty}\left\{e^{-\frac{\lambda^2}{2}}\frac{(\lambda^2/2)^k)}{k!}\right\}\left\{e^{-\frac{x}{2}}\left(\frac{x}{2}\right)^k\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{2\pi x}}\right\}\end{aligned}\tag{5.7.1030}$$

Now let us recall that if K is a random variable with a Poisson distribution and mean $\lambda^2/2$, then its distribution is equal to:

$$P_\lambda(K=k)=e^{-\lambda^2/2}\frac{(\lambda^2/2)^k}{k!}\tag{5.7.1031}$$

with $k=0,1,2,\ldots$.

Therefore:

$$\sum_{k=0}^{+\infty}\left\{e^{-\frac{\lambda^2}{2}}\frac{(\lambda^2/2)^k)}{k!}\right\}\left\{e^{-\frac{x}{2}}\left(\frac{x}{2}\right)^k\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{2\pi x}}\right\}=\sum_{k=0}^{+\infty}P_\lambda(K=k)\left\{e^{-\frac{x}{2}}\left(\frac{x}{2}\right)^k\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{2\pi x}}\right\}\tag{5.7.1032}$$

Now let us recall that the chi-square distribution is given by:

$$P_k(x)=\frac{1}{2^{\frac{k}{2}}\Gamma(k/2)}x^{\frac{k}{2}-1}e^{-\frac{x}{2}}\cdot 1_{[0,+\infty[}\tag{5.7.1033}$$

Hence:

$$\begin{aligned}P_{2k+1}(x)&=\frac{1}{2^{\frac{2k+1}{2}}\Gamma((2k+1)/2)}x^{\frac{(2k+1)}{2}-1}e^{-\frac{x}{2}}\cdot 1_{[0,+\infty[}=\frac{1}{2^{k+\frac{1}{2}}\Gamma(k+\frac{1}{2})}x^{k-\frac{1}{2}}e^{-\frac{x}{2}}\cdot 1_{[0,+\infty[}\\&=\frac{1}{2\Gamma(k+\frac{1}{2})}\left(\frac{x}{2}\right)^{k-\frac{1}{2}}e^{-\frac{x}{2}}\cdot 1_{[0,+\infty[}\end{aligned}\tag{5.7.1034}$$

So:

$$P_{2k+1}(x)2\Gamma\left(k+\frac{1}{2}\right)\left(\frac{x}{2}\right)^{\frac{1}{2}}\cdot 1_{[0,+\infty[}=\left(\frac{x}{2}\right)^k e^{-\frac{x}{2}}\tag{5.7.1035}$$

Therefore:

$$\begin{aligned}\sum_{k=0}^{+\infty}P_\lambda(K=k)\left\{e^{-\frac{x}{2}}\left(\frac{x}{2}\right)^k\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{2\pi x}}\right\}&=\sum_{k=0}^{+\infty}P_\lambda(K=k)\left\{P_{2k+1}(x)2\Gamma\left(k+\frac{1}{2}\right)\left(\frac{x}{2}\right)^{\frac{1}{2}}\cdot 1_{[0,+\infty[}\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{2\pi x}}\right\}\\&=\sum_{k=0}^{+\infty}P_\lambda(K=k)\left\{P_{2k+1}(x)\Gamma\left(k+\frac{1}{2}\right)\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{\pi}}\right\}1_{[0,+\infty[}\\&=\sum_{k=0}^{+\infty}P_\lambda(K=k)P_{2k+1}(x)\left\{\Gamma\left(k+\frac{1}{2}\right)\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{\pi}}\right\}1_{[0,+\infty[}\end{aligned}\tag{5.7.1036}$$

Now let us recall that we have proved in the section Differential and Integral Calculus (see page 1574) that:

$$\Gamma\left(k+\frac{1}{2}\right)=\frac{(2k-1)!}{2^{2k-1}(k-1)!}\sqrt{\pi} \tag{5.7.1037}$$

Therefore:

$$\begin{aligned}
&\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+1}(x)\left\{\Gamma\left(k+\frac{1}{2}\right)\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{\pi}}\right\}1_{[0,+\infty[}\\
&=\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+1}(x)\left\{\frac{(2k-1)!}{2^{2k-1}(k-1)!}\sqrt{\pi}\frac{2^{2k}k!}{(2k)!}\frac{1}{\sqrt{\pi}}\right\}1_{[0,+\infty[}\\
&=\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+1}(x)\left\{\frac{(2k-1)!}{2^{2k-1}(k-1)!}\frac{2^{2k}k!}{(2k)!}\right\}1_{[0,+\infty[}\\
&=\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+1}(x)\frac{1}{2^{-1}}\frac{k}{2k}1_{[0,+\infty[}\\
&=\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+1}(x)1_{[0,+\infty[}
\end{aligned} \tag{5.7.1038}$$

So finally the noncentral chi-square distribution function with one degree of freedom is given by:

$$\boxed{\chi_1(\lambda)=\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+1}(x)1_{[0,+\infty[}} \tag{5.7.1039}$$

Or explicitly:

$$\chi_1(\lambda)=\sum_{k=0}^{+\infty}\left\{e^{-\frac{\lambda^2}{2}}\frac{(\lambda^2/2)^k)}{k!}\right\}\left\{\frac{1}{2^{k+\frac{1}{2}}\Gamma(k+\frac{1}{2})}x^{k-\frac{1}{2}}e^{-\frac{x}{2}}\cdot 1_{[0,+\infty[}\right\} \tag{5.7.1040}$$

Remark

It can be proved (but so far we don't need this result actually anywhere in this textbook), that the general case with n degrees of freedom is given by:

$$\chi_n(\lambda)=\sum_{k=0}^{+\infty} P_\lambda(K=k)P_{2k+n}(x)1_{[0,+\infty[} \tag{5.7.1041}$$

That's actually all we need for our study later of tolerance intervals! So we will not derive the mean and variance of this distribution as is it would be useless in the actual state of this textbook!

5.7.6.19 Student Distribution

The "Student distribution" (or "Student's law") of parameter k is defined by the relation (we will prove however it's historical origin at the next page):

$$\boxed{P(x)=\frac{\Gamma\left(\dfrac{k+1}{2}\right)}{\Gamma\left(\dfrac{k}{2}\right)\sqrt{k\pi}}\left(1+\frac{x^2}{k}\right)^{-\frac{k+1}{2}}} \tag{5.7.1042}$$

with k being the degree of freedom of the χ^2 distribution underlying the construction of the Student function as we will see.

This is in reality the "centered reduced Student's distribution" because as we will see it further below, it is derived by a relation involving the centered reduced Normal law.

Let us indicate that this distribution can also be obtained in Microsoft® Excel® 11.8346 using the `TDIST( )` function and its inverse by `TINV()`.

It is indeed a distribution function because it also satisfies (remains to be proved directly, but as we will see it is the product of two distribution functions thus indirectly...):

$$\int\limits_{-\infty}^{+\infty} P_k(x)\mathrm{d}x=1 \tag{5.7.1043}$$

Let us see the easiest proof to justify the provenance of the Student distribution and that will also be very useful further in statistical inference and analysis of variance.

For this proof, remember first that:

1. If X and Y are two independent random variables with respective densities f_X, f_Y, the distribution of the pair (X, Y) has a density f satisfying (axiom of probabilities!):

$$f(x,y)=f_X(x)f_Y(y) \tag{5.7.1044}$$

2. The distribution $\mathcal{N}(0,1)$ is given by (see above):

$$f(x)=\frac{1}{\sqrt{2\pi}}e^{-x^2/2} \tag{5.7.1045}$$

3. The distribution χ_n^2 is given by (see above):

$$f(y)=\frac{1}{2^{n/2}\Gamma(n/2)}e^{-\frac{y}{2}}y^{\frac{n}{2}-1} \tag{5.7.1046}$$

   for $y\geq 0$ and $n\geq 1$.

4. The Euler function Γ is defined for all $\alpha > 0$ by (see section Differential and Integral Calculus page 1574):

$$\Gamma(\alpha)=\int\limits_{0}^{+\infty} e^{-x}x^{\alpha-1}\mathrm{d}x \tag{5.7.1047}$$

and satisfies (see section Differential and Integral Calculus page 1574):

$$\Gamma(\alpha-1)=\frac{\Gamma(\alpha)}{\alpha-1} \tag{5.7.1048}$$

for $\alpha \geq 2$.

These reminders made, now consider a random variable X that follows the distribution $\mathcal{N}(0,1)$ and Y a random variable following the distribution χ_n^2.

We assume X and Y being independent and we consider the random variable (this is at the origin the historical study of the Student distribution in the framework of statistical inference which led to define this variable for which we will deepen the origin later):

$$T=\sqrt{n}\frac{X}{\sqrt{Y}}=\frac{X}{\sqrt{Y/n}}=\frac{\mathcal{N}(0,1)}{\sqrt{\chi_n^2/n}} \tag{5.7.1049}$$

We will prove that T follows a Student distribution of parameter n.

Proof 5.47.7. Let F and f be respectively the repartition and density functions and T, f_X, f_Y the density functions of X, Y and (X,Y) respectively. Then we have for all $t\in\mathbb{R}$:

$$F(t)=P(T\leqslant t)=P\left(\sqrt{n}\frac{X}{\sqrt{Y}}\leqslant t\right)=\iint\limits_{D} f(x,y)\mathrm{d}x\mathrm{d}y=\iint\limits_{D} f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y \tag{5.7.1050}$$

where:

$$D=\left\{(x,y)\in\mathbb{R}\times\mathbb{R}^*|x\leq\frac{t\sqrt{y}}{\sqrt{n}}\right\} \tag{5.7.1051}$$

the imposed positive and non-zero value and y being due to the fact that it is under a root and furthermore at the denominator.

Thus:

$$F(t)=\iint\limits_{D} f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y=\int\limits_{0}^{+\infty} f_Y(y)\mathrm{d}y\int\limits_{-\infty}^{t\sqrt{y}/\sqrt{n}} f_X(x)\mathrm{d}x=\int\limits_{0}^{+\infty} f_Y(y)\Phi(t\sqrt{y}/\sqrt{n})\mathrm{d}y \tag{5.7.1052}$$

where because X follows a Normal $\mathcal{N}(0,1)$ distribution:

$$\Phi(u)=\int\limits_{-\infty}^{u}\frac{1}{\sqrt{2\pi}}e^{-x^2/2}\mathrm{d}x \tag{5.7.1053}$$

is the Normal centered reduced cumulative distribution.

Thus, we obtain the density distribution function of T by deriving F:

$$f(t)=F'(t)=\frac{1}{\sqrt{n}}\int\limits_0^{+\infty} f_Y(y)f_X(t\sqrt{y}/\sqrt{n})\sqrt{y}\mathrm{d}y \tag{5.7.1054}$$

because (the derivative of a function is equal to its derivatives multiplied by its inner derivative):

$$\frac{\mathrm{d}\Phi(t\sqrt{n}/\sqrt{t})}{\mathrm{d}t}=f_X(t\sqrt{n}/\sqrt{t})\frac{\sqrt{y}}{\sqrt{n}} \tag{5.7.1055}$$

Therefore:

$$\begin{aligned}
f(t)&=\frac{1}{\sqrt{n}}\int\limits_0^{+\infty} f_Y(y)f_X(t\sqrt{y}/\sqrt{n})\sqrt{y}\mathrm{d}y\\
&=\frac{1}{\sqrt{n}}\int\limits_0^{+\infty}\frac{1}{2^{n/2}\Gamma(n/2)}e^{-y/2}y^{n/2-1}\frac{1}{\sqrt{2\pi}}e^{-(t\sqrt{y}/\sqrt{n})^2/2}\sqrt{y}\mathrm{d}y\\
&=\frac{1}{\sqrt{n}}\frac{1}{2^{n/2}\Gamma(n/2)}\frac{1}{\sqrt{2\pi}}\int\limits_0^{+\infty}e^{-y/2}y^{n/2-1}e^{-(t\sqrt{y}/\sqrt{n})^2/2}\sqrt{y}\mathrm{d}y\\
\\
&=\frac{1}{2^{n/2}\Gamma(n/2)\sqrt{2\pi n}}\int\limits_0^{+\infty}e^{-\frac{y(1+t^2/n)}{2}}y^{(n-1)/2}\mathrm{d}y
\end{aligned} \tag{5.7.1056}$$

By making the change of variable:

$$u=\frac{y}{2}\left(1+\frac{t^2}{n}\right)\Rightarrow\begin{cases}\mathrm{d}y=\left(\dfrac{2}{1+\dfrac{t^2}{n}}\right)\mathrm{d}u\\ y=\frac{2}{1+\frac{t^2}{n}}u\end{cases} \tag{5.7.1057}$$

we get:

$$\begin{aligned}
f(t)&=\frac{1}{2^{n/2}\Gamma(n/2)\sqrt{2\pi n}}\left(\frac{2}{1+t^2/n}\right)^{(n+1)/2}\underbrace{\int\limits_0^{+\infty}e^{-u}u^{(n-1)/2}\mathrm{d}u}_{=\Gamma\left(\frac{n+1}{2}\right)}\\
&=\frac{\Gamma\left(\dfrac{n+1}{2}\right)}{2^{n/2}\Gamma(n/2)\sqrt{2\pi}\sqrt{n}}\left(\frac{2}{1+t^2/n}\right)^{(n+1)/2}\\
&=\frac{\Gamma\left(\frac{n+1}{2}\right)}{\Gamma(n/2)\sqrt{\pi n}}\left(1+\frac{t^2}{n}\right)^{-\frac{n+1}{2}}
\end{aligned} \tag{5.7.1058}$$

what is the Student distribution of parameter n.

■ Q.E.D.

Let us now prove what is the mean of the Student distribution:

$$T=\sqrt{n}\frac{X}{\sqrt{Y}} \tag{5.7.1059}$$

We have:

$$\mathrm{E}(T)=\mathrm{E}(\sqrt{n}X)\mathrm{E}\left(\frac{1}{\sqrt{Y}}\right) \tag{5.7.1060}$$

But $\mathrm{E}\left(\dfrac{1}{\sqrt{Y}}\right)$ exists if and only if $n\geq 2$. Effectively for $n=1$:

$$\mathrm{E}\left(\frac{1}{\sqrt{Y}}\right)=\int\limits_0^{+\infty}\frac{f_Y(y)}{\sqrt{y}}\mathrm{d}y=\frac{1}{2^{\frac{n}{2}}\Gamma(n/2)}\int\limits_0^{+\infty}e^{-\frac{y}{2}}y^{\frac{n-3}{2}}\mathrm{d}y \tag{5.7.1061}$$

and:

$$\int\limits_0^{+\infty}e^{-\frac{y}{2}}y^{\frac{1-3}{2}}\mathrm{d}y=\int\limits_0^{+\infty}\frac{e^{-\frac{y}{2}}}{y}\mathrm{d}y\geqslant\int\limits_0^{1}\frac{e^{-\frac{y}{2}}}{y}\mathrm{d}y\geqslant e^{-\frac{1}{2}}\int\limits_0^{+\infty}\frac{1}{y}\mathrm{d}y\rightarrow+\infty \tag{5.7.1062}$$

Whereas for $n\geq 2$ we have:

$$\int\limits_0^{+\infty}e^{-\frac{y}{2}}y^{\frac{n-3}{2}}\mathrm{d}y=2^{\frac{n-1}{2}}\int\limits_0^{+\infty}e^{-u}u^{\frac{n-3}{2}}\mathrm{d}u=2^{\frac{n-1}{2}}\Gamma\left(\frac{n-1}{2}\right)<+\infty \tag{5.7.1063}$$

Thus, for $n=1$ the mean does not exist.

So for $n\geq 2$:

$$\mathrm{E}(T)=\sqrt{n}\underbrace{\mathrm{E}(X)}_{=0}\mathrm{E}\left(\frac{1}{\sqrt{Y}}\right)=0 \tag{5.7.1064}$$

Now let us see the value of the variance. So we have:

$$\mathrm{V}(T)=\mathrm{E}(T^2)-\mathrm{E}(T)^2 \tag{5.7.1065}$$

First we will discuss the existence of $\mathrm{E}(T^2)$. We have trivially:

$$\mathrm{E}(T^2)=nE\left(\frac{X^2}{Y}\right)=n\mathrm{E}(X^2)\mathrm{E}\left(\frac{1}{Y}\right) \tag{5.7.1066}$$

X follows a Normal centered reduced distribution thus:

$$\mathrm{V}(X)=1=\mathrm{E}(X^2)-\underbrace{\mathrm{E}(X)^2}_{=0}=\mathrm{E}(X^2)\quad\Rightarrow\quad\mathrm{E}(X^2)=1 \tag{5.7.1067}$$

With regard to $\mathrm{E}\left(\dfrac{1}{Y}\right)$ we have:

$$\mathrm{E}\left(\frac{1}{Y}\right)=\int\limits_0^{+\infty}\frac{f_Y(y)}{y}\mathrm{d}y=\frac{1}{2^{\frac{n}{2}}\Gamma(n/2)}\int\limits_0^{+\infty}e^{-\frac{y}{2}}y^{\frac{n}{2}-2}\mathrm{d}y=\frac{1}{2^{\frac{n}{2}}\Gamma(n/2)}\int\limits_0^{+\infty}e^{-u}u^{\frac{n}{2}-2}\mathrm{d}u=\frac{\Gamma\left(\frac{n}{2}-1\right)}{2\Gamma(n/2)} \tag{5.7.1068}$$

where we made the change of variable $u=y/2$.

But the integral defining $\Gamma\left(\dfrac{n}{2}-1\right)$ converges only if $n\geq 3$.

Therefore $\mathrm{E}(T^2)$ exists if and only if $n\geq 3$ so it's value is according to the properties of the Euler Gamma function demonstrated in the chapter of Differential and Integral Calculus:

$$n\mathrm{E}\left(T\right)=n\frac{\Gamma\left(\frac{n}{2}-1\right)}{2\Gamma(n/2)}=\frac{n}{n-2} \tag{5.7.1069}$$

Therefore for $n\geq 3$:

$$\mathrm{V}(T)=\frac{n}{n-2} \tag{5.7.1070}$$

It is also important to note that this law is symmetrical about 0!

Here is a plot example of the Student distribution and cumulative distribution for the parameter $k=3$ (for more plots about this distribution see further below on page 388):

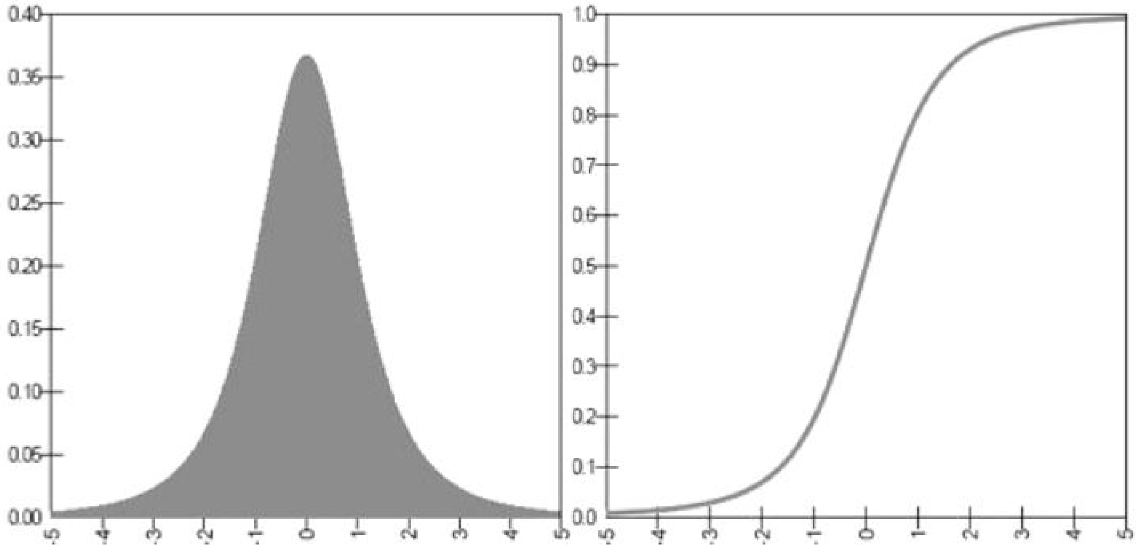

Figure 5.151: **Student T law (mass and cumulative distribution function)**

Finally for people that don't have an access to spreadsheet or statistical software:

5.7.6.19.1 Multivariate Student T-distribution

There is sadly many various different definition of the "multivariate T-distribution" (we speak then of multivariate T-distribution "candidates"). We will focus here on the one often named "canonical multivariate T-distribution".

First if the reader redo the proof of the derivation of the T distribution but use $\mathcal{N}(0,\sigma^2)$ instead of $\mathcal{N}(0,1)$, the reader should easily see that the result is:

$$f(t)=\frac{\Gamma\left(\frac{n+1}{2}\right)}{\Gamma(n/2)\sqrt{\pi\sigma n}}\left(1+\frac{t^2}{n\sigma^2}\right)^{-\frac{n+1}{2}} \tag{5.7.1071}$$

that is named the "centered Student distribution" (as it is not reduced!).

And using the rule of thumb it's also quite easy to guess that if the variable was not centered then we would have:

$$f(t)=\frac{\Gamma\left(\frac{n+1}{2}\right)}{\Gamma(n/2)\sqrt{\pi\sigma n}}\left(1+\frac{(t-\mu)^2}{n\sigma^2}\right)^{-\frac{n+1}{2}} \tag{5.7.1072}$$

that is the (real) "Student's law" (i.e. the non-centered and non-reduced one...)!

The T-distribution above is obviously a special case of the multivariate T-distribution with number of variables $n=1$, i.e. random vector $x\in\mathbb{R}$, mean $\mu=0$ and covariance matrix $\Sigma=1$.

We can guess by the rule of thumb that the probability density function of the "canonical multivariate T-distribution" knowing how the multivariate Normal distribution looks like (see page 720) is given by:

$$\boxed{T(\vec{x};\vec{\mu},\Sigma,\nu)=\frac{\Gamma([\nu+n]/2)}{\Gamma(\nu/2)\sqrt{(\nu\pi)^n|\Sigma|}}\left[1+\frac{1}{\nu}(\vec{x}-\vec{\mu})^{\mathrm{T}}\Sigma^{-1}(\vec{x}-\vec{\mu})\right]^{-(\nu+n)/2}} \tag{5.7.1073}$$

with $\vec{x}\in\mathbb{R}^n$ and Σ being the $n\times n$ variance-covariance matrix.

Setting $n=1$, such that $x\in\mathbb{R}$, as well as $\mu=0$ and $\Sigma=1$, we get:

$$\begin{aligned}T(\vec{x};0,1,\nu)&=\frac{\Gamma([\nu+1]/2)}{\Gamma(\nu/2)\sqrt{(\nu\pi)^1|1|}}\left[1+\frac{1}{\nu}(x-0)^{\mathrm{T}}1^{-1}(x-0)\right]^{-(\nu+1)/2}\\&=\frac{\Gamma([\nu+1]/2)}{\Gamma(\nu/2)\sqrt{\nu\pi}}\left[1+\frac{x^2}{\nu}\right]^{-(\nu+1)/2}\\&=\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)\sqrt{\nu\pi}}\left[1+\frac{x^2}{\nu}\right]^{-\frac{\nu+1}{2}}\end{aligned} \tag{5.7.1074}$$

which is equivalent to the probability density function of the (centered-reduced) T-distribution.

5.7.6.20 Fisher Distribution

The "Fisher distribution" (or "Fisher-Snedecor distribution") of parameters k and l is defined by the relation:

$$\boxed{P(x)=\frac{\Gamma\left(\dfrac{k+1}{2}\right)\left(\dfrac{k}{l}\right)^{\frac{k}{2}}}{\Gamma\left(\dfrac{k}{2}\right)\Gamma\left(\dfrac{l}{2}\right)}x^{\frac{k}{2}-1}\left(1+\frac{kx}{l}\right)^{-\frac{k+l}{2}}} \tag{5.7.1075}$$

if $x \geq 0$ (see the plot further below on page 388). The parameters k and l are positive integers and correspond to the two degrees of freedom of the underlying chi-square distributions. This distribution is often denoted by $F_{k,l}$ or by $F(k,l)$ and can be obtained in Microsoft® Excel® 11.8346 with the `FDIST( )` function.

It is indeed a distribution function because it satisfies the property (remains to us to prove that directly but as we will see, it is the product of two distribution functions therefore indirectly...):

$$\int\limits_0^{+\infty} F_{k,l}(x)\mathrm{d}x=1 \tag{5.7.1076}$$

Let us see the easiest proof to justify the provenance of the Fisher distribution and that we will be us also very useful further in statistical inference and analysis of variance.

For this proof, recall that:

1. The distribution χ^2_n is given by (see above):

$$f(y)=\frac{1}{2^{n/2}\Gamma(n/2)}e^{-y/2}y^{n/2-1} \tag{5.7.1077}$$

for $y \geq 0$ and $n \geq 1$.

2. The Euler Gamma function Γ is defined for all $\alpha > 0$ by (see section Differential and Integral Calculus page 1574):

$$\Gamma(\alpha)=\int\limits_0^{+\infty} e^{-x}x^{\alpha-1}\mathrm{d}x \tag{5.7.1078}$$

Let X, Y be two independent random variables following respectively the distributions χ^2_n and χ^2_m.

We consider the random variable:

$$T=\frac{X/n}{Y/m}=\frac{\chi^2_n/n}{\chi^2_m/m} \tag{5.7.1079}$$

We will prove that the distribution of T is the Fisher-Snedecor distribution of parameters n, m.

Let us note for this purpose F and f the cumulative and density function of T and f_X, f_Y, f density functions of X, Y and respectively (X, Y). We have for all $t \in \mathbb{R}$:

$$F(t)=P(T\leqslant t)=P\left(\frac{X/n}{Y/m}\leqslant t\right)=\iint\limits_{D} f(x,y)\mathrm{d}x\mathrm{d}y=\iint\limits_{D} f_X(x)f_Y(y)\mathrm{d}x\mathrm{d}y \tag{5.7.1080}$$

where:

$$D=\left\{(x,y)\in\mathbb{R}^*\times\mathbb{R}^* | x\leq\frac{nt}{m}y\right\} \tag{5.7.1081}$$

where the imposed positive values comes in fact that behind them there is a chi-square for x and y. Therefore:

$$F(t)=\int\limits_{0}^{+\infty} f_Y(y)\mathrm{d}y\int\limits_{0}^{\frac{nty}{m}} f_X(x)\mathrm{d}y \tag{5.7.1082}$$

We obtain the density function of T by deriving F. First the inner derivative:

$$f(t)=F'(t)=\frac{n}{m}\int\limits_{0}^{+\infty} f_Y(y)f_X\left(\frac{nty}{m}y\right)y\mathrm{d}y \tag{5.7.1083}$$

Then explicitly because:

$$f(y)=\frac{1}{2^{m/2}\Gamma(m/2)}e^{-y/2}y^{m/2-1} \quad \text{and} \quad f\left(\frac{nt}{m}y\right)=\frac{1}{2^{n/2}\Gamma(n/2)}e^{-\frac{nt}{2m}y}\left(\frac{nt}{m}y\right)^{n/2-1} \tag{5.7.1084}$$

we then have:

$$\begin{aligned}
f(t)&=\frac{n}{m}\int\limits_{0}^{+\infty}\frac{1}{2^{m/2}\Gamma(m/2)}e^{-y/2}y^{\frac{m}{2}-1}\frac{1}{2^{\frac{n}{2}}\Gamma(n/2)}e^{-\frac{nt}{2m}y}\left(\frac{nt}{m}y\right)^{\frac{n}{2}-1}y\mathrm{d}y\\
&=\frac{1}{2^{n/2}\Gamma(n/2)2^{m/2}\Gamma(m/2)}\frac{n}{m}\int\limits_{0}^{+\infty}e^{-y/2}y^{m/2-1}e^{-\frac{nt}{2m}y}\left(\frac{nt}{m}y\right)^{\frac{n}{2}-1}y\mathrm{d}y\\
&=\frac{1}{2^{n/2}\Gamma(n/2)2^{m/2}\Gamma(m/2)}\frac{n}{m}\left(\frac{nt}{m}\right)^{n/2-1}\int\limits_{0}^{+\infty}e^{-y/2}y^{m/2-1}e^{-\frac{nt}{2m}y}y^{n/2-1}y\mathrm{d}y\\
&=\frac{1}{2^{\frac{n+m}{2}}\Gamma(n/2)\Gamma(m/2)}\frac{n}{m}\left(\frac{nt}{m}\right)^{\frac{n}{2}-1}\int\limits_{0}^{+\infty}y^{\frac{n+m}{2}-1}e^{-\frac{y}{2}\left(1+\frac{nt}{m}\right)}\mathrm{d}y
\end{aligned} \tag{5.7.1085}$$

By making the change of variable:

$$u=\frac{y}{2}\left(1+\frac{nt}{m}\right)\Rightarrow y=\frac{2u}{1+\frac{nt}{m}}\Rightarrow \mathrm{d}y=\mathrm{d}u\frac{2}{1+\frac{nt}{m}} \tag{5.7.1086}$$

we get:

$$\begin{aligned}
f(t) &= \frac{n}{m}\frac{1}{2^{\frac{n+m}{2}}\Gamma(n/2)\Gamma(m/2)}\left(\frac{nt}{m}\right)^{\frac{n}{2}-1}\left(\frac{2}{1+\frac{nt}{m}}\right)^{\frac{n+m}{2}}\underbrace{\int\limits_0^{+\infty} u^{\frac{n+m}{2}-1}e^{-u}\mathrm{d}u}_{\Gamma\left(\frac{n+m}{2}\right)} \\
&= \frac{\frac{n}{m}\Gamma\left(\frac{n+m}{2}\right)}{\Gamma(n/2)\Gamma(m/2)}\left(\frac{nt}{m}\right)^{\frac{n}{2}-1}\left(1+\frac{nt}{m}\right)^{-\frac{n+m}{2}} \\
&= \frac{\left(\frac{n}{m}\right)^{\frac{n}{2}}\Gamma\left(\frac{n+m}{2}\right)}{\Gamma(n/2)\Gamma(m/2)}t^{\frac{n}{2}-1}\left(1+\frac{nt}{m}\right)^{-\frac{n+m}{2}}
\end{aligned} \tag{5.7.1087}$$

For the people that may not have access to a spreadsheet or statistical software here are some useful tables:

5.7.6.21 General Folded Normal Distribution

The "folded Normal distribution" is the distribution of the absolute value of a random variable with a Normal distribution[39]. As we have mentioned before, the Normal distribution is perhaps the most important in probability and is used to model an incredible variety of random phenomena. Since one may only be interested in the magnitude of a Normally distributed variable, the folded Normal arises in a very natural way especially in Finance and Industrial Engineering for Design of Experiments (see section Industrial Engineering page 8780). The name stems from the fact that the probability measure of the Normal distribution on $]-\infty,0]$ is folded over to $[0,+\infty[$.

Definition (#5.7.134): Suppose that X has a Normal distribution with mean $\mu\in\mathbb{R}$ and standard deviation $\sigma\in[0,+\infty[$. Then $Y=|X|$ has the fold Normal distribution with parameters μ and σ.

Suppose that Z follows the standard Normal distribution. Let us recall that then Z has probability density function ϕ and distribution function Φ given by:

$$\begin{aligned}\phi(z)&=\frac{1}{\sqrt{2\pi}}e^{-z^2/2}\\ \Phi(z)&=\int\limits_{-\infty}^{z}\phi(x)\mathrm{d}x=\int\limits_{-\infty}^{z}\frac{1}{\sqrt{2\pi}}e^{-x^2/2}\mathrm{d}x\end{aligned}\tag{5.7.1088}$$

with $z\in\mathbb{R}$.

If $\mu\in\mathbb{R}$ and $\sigma\in[0,+\infty[$, then $X=\mu+\sigma Z$ has the Normal distribution with mean μ and standard deviation σ, and therefore it is obvious at this level that:

$$Y=|X|=|\mu+\sigma Z|\tag{5.7.1089}$$

has the folded Normal distribution with parameters μ and σ.

Now let us determine the cumulative probability CDF function of such a variable! For $y\in[0,+\infty[$:

$$\begin{aligned}F(y)=P(Y\leq y)&=P(|X|\leq y)=P(|\mu+\sigma Z|\leq y)=P(-y\leq\mu+\sigma Z\leq y)\\ &=P\left(\frac{-y-\mu}{\sigma}\leq Z\leq\frac{y-\mu}{\sigma}\right)=\Phi\left(\frac{y-\mu}{\sigma}\right)-\Phi\left(\frac{-y-\mu}{\sigma}\right)\end{aligned}\tag{5.7.1090}$$

Since $\Phi(-Z)=1-\Phi(Z)$ we have:

$$\begin{aligned}F(y)&=\Phi\left(\frac{y-\mu}{\sigma}\right)-\Phi\left(\frac{-y-\mu}{\sigma}\right)=\Phi\left(\frac{y-\mu}{\sigma}\right)+\Phi\left(\frac{y+\mu}{\sigma}\right)-1\\ &=\int\limits_{0}^{y}\frac{1}{\sigma\sqrt{2\pi}}\left\{e^{-\frac{1}{2}\left(\frac{x+\mu}{\sigma}\right)^2}+e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}\right\}\mathrm{d}x\end{aligned}\tag{5.7.1091}$$

We cannot compute the quantile function F^{-1} in closed form, but values of this function can be approximated.

---

[39] The majority of the text below comes from `http://www.math.uah.edu/stat/`

It comes therefore immediately that Y has probability density function f given by:

$$\boxed{f(|Y|)=\frac{1}{\sigma\sqrt{2\pi}}\left\{e^{-\frac{1}{2}\left(\frac{x+\mu}{\sigma}\right)^2}+e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}\right\}} \tag{5.7.1092}$$

This follow from differentiating the CDF with respect to y as we know!

Now as always in this textbook we will focus only in what we need for the applications in the other chapters! So as we don't need the moments of the folder Normal distribution we will not calculate them. The only purpose of the above development were to build the tools to be able to introduce a special case of the folder Normal distribution.

5.7.6.21.1 Half-Normal distribution

In probability theory and statistics, the "half-Normal distribution" is a special case of the folded Normal distribution.

Let X follow an ordinary Normal distribution, $\mathcal{N}(0,\sigma^2)$, then $Y=|X|$ follows a half-Normal distribution. Thus, the half-Normal distribution is a fold at the mean of an ordinary Normal distribution with mean $\mu=0$.

Thus, let $Y=|\sigma Z|=\sigma|Z|$ where Z has a standard Normal distribution and $\sigma\in[0,+\infty[$. Clearly σ is a scale parameter, unlike the case for the general folded Normal distribution. The distribution of Y when $\sigma=1$, $Y=|Z|$ has the "standard half-Normal distribution".

As the half-Normal distribution is just a special case of the folded Normal distribution with $\mu=0$ it comes immediately:

$$\boxed{f(y)=\frac{1}{\sigma}\sqrt{\frac{2}{\pi}}e^{-\frac{y^2}{2\sigma^2}}} \tag{5.7.1093}$$

with $y\in\mathbb{R}^+$ and sometimes denoted $\mathcal{HN}(0,\sigma^2)$.

Now what interest us for the others chapters of this textbook (especially Design of Experiments) are the moments of that latter!

To calculate them, first remember that:

$$\phi(z)=\frac{1}{\sqrt{2\pi}}e^{-\frac{1}{2}z^2} \tag{5.7.1094}$$

with $z\in\mathbb{R}$. Therefore it is immediate that:

$$\phi'(z)=-z\phi(z) \tag{5.7.1095}$$

Also remember that we have already proved that:

$$\text{E}(Z)=0 \qquad \text{E}(Z^2)=\text{V}(Z)=1 \tag{5.7.1096}$$

We first need to determiner the moments for the Normal distribution! So for $n \in \mathbb{N}^+$:

$$\mathrm{E}(Z^{n+1}) = \int\limits_{-\infty}^{+\infty} z^{n+1}\phi(z)\mathrm{d}z = \int\limits_{-\infty}^{+\infty} z^n z\phi(z)\mathrm{d}z = -\int\limits_{-\infty}^{+\infty} z^n\phi'(z)\mathrm{d}z \tag{5.7.1097}$$

Now we integrate by parts (see section Differential and Integral Calculus page 1532), with $u = z^n$ and $\mathrm{d}v = \phi'(z)\mathrm{d}z$ to get:

$$\mathrm{E}(Z^{n+1}) = -z^n\phi(z)\Big|_{-\infty}^{+\infty} + \int\limits_{-\infty}^{+\infty} nz^{n-1}\phi(z)\mathrm{d}z = 0 + n\mathrm{E}(Z^{n-1}) \tag{5.7.1098}$$

Therefore for $n \in \mathbb{N}$, with $n > 1$:

$$\mathrm{E}(Z^{n+1}) = n\mathrm{E}(Z^{n-1}) \tag{5.7.1099}$$

The moments of the standard Normal distribution are now easy to compute. First we know that:

- $\mathrm{E}(Z) = 0$
- $\mathrm{E}(Z^2) = 1$

Therefore:

- $\mathrm{E}(Z) = 0$
- $\mathrm{E}(Z^2) = 1$
- $\mathrm{E}(Z^3) = \mathrm{E}(Z^{2+1}) = 2 \cdot \mathrm{E}(Z^{2-1}) = 2 \cdot \mathrm{E}(Z) = 0$
- $\mathrm{E}(Z^4) = \mathrm{E}(Z^{3+1}) = 3 \cdot \mathrm{E}(Z^{3-1}) = 3 \cdot \mathrm{E}(Z^2) = 3 \cdot 1 = 1 \cdot 3 = 3$
- $\mathrm{E}(Z^5) = \mathrm{E}(Z^{4+1}) = 4 \cdot \mathrm{E}(Z^{4-1}) = 4 \cdot \mathrm{E}(Z^3) = 4 \cdot 0 = 0$
- $\mathrm{E}(Z^6) = \mathrm{E}(Z^{5+1}) = 5 \cdot \mathrm{E}(Z^{5-1}) = 5 \cdot \mathrm{E}(Z^4) = 5 \cdot 3 = 1 \cdot 3 \cdot 5 = 15$
- $\mathrm{E}(Z^7) = \mathrm{E}(Z^{6+1}) = 6 \cdot \mathrm{E}(Z^{6-1}) = 6 \cdot \mathrm{E}(Z^5) = 6 \cdot 0 = 0$
- $\mathrm{E}(Z^8) = \mathrm{E}(Z^{7+1}) = 7 \cdot \mathrm{E}(Z^{7-1}) = 7 \cdot \mathrm{E}(Z^6) = 7 \cdot 15 = 1 \cdot 3 \cdot 5 \cdot 7$
- $\ldots$

Therefore we see that for the odd powers, that is to say Z^{2n+1} with $n \in \mathbb{N}$ then:

$$\mathrm{E}(Z^{2n+1}) = 0 \tag{5.7.1100}$$

and for even powers:

$$\mathrm{E}(Z^{2n}) = 1 \cdot 3 \cdot \ldots \cdot (2n-1) = \frac{(2n)!}{n!2^n} \tag{5.7.1101}$$

It follows for $X=\mathcal{N}(0,\sigma)$ (just check with the special case of $n=0$ and $n=1$):

$$\boxed{\mathrm{E}(X^{2n+1})=0 \qquad \mathrm{E}(X^{2n})=\sigma^{2n}\frac{(2n)!}{n!2^n}} \tag{5.7.1102}$$

The moments of the half-Normal distribution can now be computed explicitly.

First it should be quite obvious by construction that the even order moments of Y are the same as the even order moments of Z (in both case the values are all positive and therefore equal). Hence:

$$\mathrm{E}(Y^{2n})=\sigma^{2n}\frac{(2n)!}{n!2^n} \tag{5.7.1103}$$

For the odd order moments we must use (see above):

$$f(Y)=\frac{1}{\sigma}\sqrt{\frac{2}{\pi}}e^{-\frac{y^2}{2\sigma^2}} \tag{5.7.1104}$$

with $x\in\mathbb{R}^+$. Therefore by definition:

$$\mathrm{E}(Y^{2n+1})=\int\limits_0^{+\infty} y^{2n+1}f(y)\mathrm{d}y=\int\limits_0^{+\infty} y^{2n+1}\frac{1}{\sigma}\sqrt{\frac{2}{\pi}}e^{-\frac{y^2}{2\sigma^2}}\mathrm{d}y \tag{5.7.1105}$$

hence:

$$\mathrm{E}(Y^{2n+1})=\frac{1}{\sigma}\sqrt{\frac{2}{\pi}}\int\limits_0^{+\infty} y^{2n+1}e^{-\frac{y^2}{2\sigma^2}}\mathrm{d}y \tag{5.7.1106}$$

Now we make the change of variable $u=y^2/(2\sigma^2)$, therefore first we have (this is obvious):

$$e^{-\frac{y^2}{2\sigma^2}}=e^{-u} \tag{5.7.1107}$$

and:

$$\mathrm{d}u=\frac{2y\mathrm{d}y}{2\sigma^2}\Leftrightarrow \mathrm{d}y=\frac{\sigma^2}{y}\mathrm{d}u \tag{5.7.1108}$$

Therefore we have so far:

$$\sigma\sqrt{\frac{2}{\pi}}\int\limits_0^{+\infty} y^{2n+1}\frac{1}{y}e^{-u}\mathrm{d}u=\sigma\sqrt{\frac{2}{\pi}}\int\limits_0^{+\infty}\left(y^2\right)^n e^{-u}\mathrm{d}u \tag{5.7.1109}$$

So finally:

$$\mathrm{E}(Y^{2n+1})=\sigma\sqrt{\frac{2}{\pi}}\int\limits_0^{+\infty}\left(2\sigma^2u\right)^n e^{-u}\mathrm{d}u=\sigma^{2n+1}2^n\sqrt{\frac{2}{\pi}}\int\limits_0^{+\infty}u^ne^{-u}\mathrm{d}u \tag{5.7.1110}$$

We recognize in this expression the Gamma Euler function integral (see section Differential and Integral Calculus page 1574)! Therefore it is immediate that:

$$\mathrm{E}(Y^{2n+1})=\sigma\sqrt{\frac{2}{\pi}}\Gamma_0(u)=\sigma^{2n+1}2^n\sqrt{\frac{2}{\pi}}n! \tag{5.7.1111}$$

So as summary:

$$\mathrm{E}(Y^{2n})=\sigma^{2n}\frac{(2n)!}{n!2^n} \qquad \mathrm{E}(Y^{2n+1})=\sigma^{2n+1}2^n\sqrt{\frac{2}{\pi}}n! \tag{5.7.1112}$$

So finally we get the result we need for some properties of the Brownian motion in finance:

$$\begin{aligned}&\mathrm{E}(Y)=\mathrm{E}(Y^{2\cdot 0+1})=\sigma\sqrt{\frac{2}{\pi}}\\&\mathrm{V}(Y)=\mathrm{E}(Y^2)-(\mathrm{E}(Y))^2=\mathrm{E}(Y^{2\cdot 1})-(\mathrm{E}(Y))^2=\sigma^2-\left(\sigma\sqrt{\frac{2}{\pi}}\right)^2=\sigma^2\left(1-\frac{2}{\pi}\right)\end{aligned} \tag{5.7.1113}$$

But still one property is missing and now for our needs in the section of Industrial Engineering (page 8780): the value of the Median!

So let M_e denote the median of the half-Normal distribution. Then by definition it follows that:

$$0.50=F(M_e)=\int\limits_0^{M_e} f(y)\mathrm{d}y=\frac{1}{\sigma}\sqrt{\frac{2}{\pi}}\int\limits_0^{M_e} e^{-\frac{1}{2}\left(\frac{y}{\sigma}\right)^2}\mathrm{d}y \tag{5.7.1114}$$

Substituting $y/(\sqrt{2}\sigma)=u$ we have:

$$0.50=F(M_e)=\frac{2}{\sqrt{\pi}}\int\limits_0^{\frac{M_e}{\sqrt{2}\sigma}} e^{-u^2}\mathrm{d}u \tag{5.7.1115}$$

We recognize here the Error function (see section Thermodynamics page 3697). Therefore:

$$0.50=F(M_e)=\mathrm{erf}\left(\frac{M_e}{\sqrt{2}\sigma}\right) \tag{5.7.1116}$$

Therefore:

$$\mathrm{erf}^{-1}(0.50)=\frac{M_e}{\sqrt{2}\sigma} \tag{5.7.1117}$$

A spreadsheet software like Microsoft® Excel® gives us for the complementary Error function:

```
=ERFC(0.5)=0.479500122
```

Therefore:

$$\boxed{M_e\cong 0.479500122\sqrt{2}\sigma\cong 0.67\sigma} \tag{5.7.1118}$$

The technique that we will see in the section Industrial Engineering (page 8896) makes the approximation that therefore:

$$1.5\cdot M_e\cong\sigma \tag{5.7.1119}$$

indeed... it's engineering...

5.7.6.22 Laplace Distribution

In probability theory and statistics, the "Laplace distribution" is a continuous probability distribution named also sometimes named the "double exponential distribution", because it can be thought of as two exponential distributions (with an additional location parameter) spliced together back-to-back (although the term is also sometimes used to refer to the Gumbel distribution). This distribution has many applications but the one that interest us in this textbook is the LASSO regression (see section Numerical Methods page 6441).

The difference between two independent identically distributed exponential random variables is governed by a Laplace distribution.

Proof 5.47.8. Let X_1 and X_2 be independent exponential random variable with population means α_1 and α_2 respectively. Define $Y = X_1 - X_2$. The goal is to find the distribution of Y by the cumulative distribution function technique. First we know that:

$$f_{X_1}(x_1) = \frac{1}{\alpha_1}e^{-x_1/\alpha_1} \qquad x_1 > 0 \tag{5.7.1120}$$

and:

$$f_{X_2}(x_x) = \frac{1}{\alpha_2}e^{-x_2/\alpha_2} \qquad x_2 > 0 \tag{5.7.1121}$$

By independence, it follows that the joint probability density function of X_1 and X_2 is:

$$f_{X_1,X_2}(x_1,x_2) = \frac{1}{\alpha_1\alpha_2}e^{-x_1/\alpha_1}e^{-x_2/\alpha_2} \qquad x_1 > 0, x_2 > 0 \tag{5.7.1122}$$

We want $F_Y(y) = P(Y \leq y)$ where $-\infty < y < +\infty$. Looking at the support of $f_{X_1,X_2}(x_1,x_2)$ given above, we see that the resulting cumulative distribution function for Y will (must) be piecewise, where the pieces are separated at $y = 0$. So we first consider the case where $y \leq 0$. The double integral giving us the cumulative distribution function $F_Y(y)$ of $y \leq 0$ is:

$$\begin{aligned}
F_Y(y) &= P(Y \leq y) = P(X_1 - X_2 \leq y) = P(X_2 \geq X_1 - y)\\
&= \int_0^{+\infty}\int_{x_1-y}^{+\infty} f_{X_1,X_2}(x_1,x_2)\mathrm{d}x_2\mathrm{d}x_1 = \int_0^{+\infty}\int_{x_1-y}^{+\infty}\frac{1}{\alpha_1\alpha_2}e^{-x_1/\alpha_1}e^{-x_2/\alpha_2}\mathrm{d}x_2\mathrm{d}x_1\\
&= \frac{\alpha_2}{\alpha_1+\alpha_2}e^{y/\alpha_2} \qquad y \leq 0
\end{aligned} \tag{5.7.1123}$$

For $y > 0$, the cumulative distribution function of Y is:

$$\begin{aligned}
F_Y(y) &= P(Y \leq y) = 1 - P(Y > y) = 1 - P(X_1 - X_2 > y) = 1 - P(X_2 \geq X_1 - y)\\
&= 1 - \int_y^{+\infty}\int_0^{x_1-y} f_{X_1,X_2}(x_1,x_2)\mathrm{d}x_2\mathrm{d}x_1 = 1 - \int_y^{+\infty}\int_0^{x_1-y}\frac{1}{\alpha_1\alpha_2}e^{-x_1/\alpha_1}e^{-x_2/\alpha_2}\mathrm{d}x_2\mathrm{d}x_1\\
&= 1 - \frac{\alpha_1}{\alpha_1+\alpha_2}e^{-y/\alpha_1} \qquad y > 0
\end{aligned} \tag{5.7.1124}$$

Differentiating with respect to y gives:

$$f_Y(y)=\begin{cases}\dfrac{e^{y/\alpha_2}}{\alpha_1+\alpha_2} & \text{if } y\leq 0\\ \dfrac{e^{-y/\alpha_1}}{\alpha_1+\alpha_2} & \text{if } y>0\end{cases} \tag{5.7.1125}$$

which is the probability density function of a Laplace random variable with parameters α_1 and α_2.

■ Q.E.D.

A random variable has a $\mathcal{L}(\mu,b)$ distribution if its probability density function is:

$$\boxed{\mathcal{L}(x\mid\mu,b)=\frac{1}{2b}\exp\left(-\frac{|x-\mu|}{b}\right)=\frac{1}{2b}\begin{cases}\exp\left(-\frac{\mu-x}{b}\right) & \text{if } x<\mu\\ \exp\left(-\frac{x-\mu}{b}\right) & \text{if } x\geq\mu\end{cases}} \tag{5.7.1126}$$

Here, μ is a location parameter and $b>0$, which is sometimes referred to as the diversity, is a scale parameter. If $\mu=0$ and $b=1$, the positive half-line is exactly an exponential distribution scaled by $1/2$.

Notice that the Laplace distribution is often denoted:

$$\mathcal{L}(x\mid\mu,\sigma)=\frac{1}{2\sigma}\exp\left(-\frac{|x-\mu|}{\sigma}\right) \tag{5.7.1127}$$

The probability density function of the Laplace distribution is also reminiscent of the Normal distribution; however, whereas the Normal distribution is expressed in terms of the squared difference from the mean μ, the Laplace density is expressed in terms of the absolute difference from the mean. Consequently, the Laplace distribution has fatter tails than the Normal distribution.

The Laplace distribution is easy to integrate (if one distinguishes two symmetric cases) due to the use of the absolute value function. Its cumulative distribution function is as follows:

$$\begin{aligned}F(x)&=\int\limits_{-\infty}^{x} f(u)\,\mathrm{d}u=\begin{cases}\frac{1}{2}\exp\left(\frac{x-\mu}{b}\right) & \text{if } x<\mu\\ 1-\frac{1}{2}\exp\left(-\frac{x-\mu}{b}\right) & \text{if } x\geq\mu\end{cases}\\ &=\frac{1}{2}+\frac{1}{2}\text{sng}(x-\mu)\left(1-\exp\left(-\frac{|x-\mu|}{b}\right)\right)\end{aligned} \tag{5.7.1128}$$

Let us now derive the mean and variance of the Laplace distribution adopting the following notation:

$$\mathcal{L}(x\mid\mu,\sigma)=\frac{1}{2\sigma}\exp\left(-\frac{|x-\mu|}{\sigma}\right) \tag{5.7.1129}$$

Let $u = x - \mu$, then we have $x = u + \mu$ and $\mathrm{d}x = \mathrm{d}u$. By linearity we have $\mathrm{E}(X) = \mathrm{E}(U+\mu) = \mathrm{E}(U) + \mu$, hence:

$$\begin{aligned}
\mathrm{E}[X] &= \frac{1}{2\sigma}\int\limits_{-\infty}^{+\infty} u\, e^{-\frac{|u|}{\sigma}}\,\mathrm{d}u + \mu \\
&= \underbrace{\frac{1}{2\sigma}\int\limits_{-\infty}^{0} u\, e^{\frac{u}{\sigma}}\,\mathrm{d}u}_{\text{set } u=-u} + \frac{1}{2\sigma}\int\limits_{0}^{+\infty} u\, e^{-\frac{u}{\sigma}}\,\mathrm{d}u + \mu \\
&= -\frac{1}{2\sigma}\int\limits_{0}^{+\infty} u\, e^{-\frac{u}{\sigma}}\,\mathrm{d}u + \frac{1}{2\sigma}\int\limits_{0}^{+\infty} u\, e^{-\frac{u}{\sigma}}\,\mathrm{d}u + \mu \\
&= \mu
\end{aligned} \tag{5.7.1130}$$

and:

$$\begin{aligned}
\mathrm{E}\left[X^2\right] &= \mathrm{E}\left[(U+\mu)^2\right] = \mathrm{E}\left[U^2\right] + 2\mu\mathrm{E}\left[U\right] + \mu^2 = \mathrm{E}\left[U^2\right] + 2\mu\,\mathrm{E}\left[X-\mu\right] + \mu^2 \\
&= \frac{1}{2\sigma}\int\limits_{-\infty}^{+\infty} u^2 e^{-\frac{|u|}{\sigma}}\,\mathrm{d}u + \mu^2 = \underbrace{\frac{1}{2\sigma}\int\limits_{-\infty}^{0} u^2 e^{\frac{u}{\sigma}}\,\mathrm{d}u}_{\text{set } u=-u} + \frac{1}{2\sigma}\int\limits_{0}^{+\infty} u^2 e^{-\frac{u}{\sigma}}\,\mathrm{d}u + \mu^2 \\
&= \frac{1}{2\sigma}\int\limits_{0}^{+\infty} u^2 e^{-\frac{u}{\sigma}}\,\mathrm{d}u + \frac{1}{2\sigma}\int\limits_{0}^{+\infty} u^2 e^{-\frac{u}{\sigma}}\,\mathrm{d}u + \mu^2 \\
&= \underbrace{\frac{1}{\sigma}\int\limits_{0}^{+\infty} u^2 e^{-\frac{u}{\sigma}}\,\mathrm{d}u}_{\text{set } v=\frac{u}{\sigma}} + \mu^2 = \sigma^2\int\limits_{0}^{+\infty} v^2 e^{-v}\,dv + \mu^2 \\
&= 2\sigma^2 + \mu^2
\end{aligned} \tag{5.7.1131}$$

where:

$$\Gamma(n+1) = \int\limits_{0}^{+\infty} v^n e^{-v}\,\mathrm{d}v = n! \qquad \text{for } n \text{ natural number.} \tag{5.7.1132}$$

Thus:

$$\mathrm{V}[X] = \mathrm{E}\left[X^2\right] - \left(\mathrm{E}[X]\right)^2 = 2\sigma^2 \tag{5.7.1133}$$

5.7.6.23 Benford Distribution

This distribution was discovered first in 11881 (holocene calendar) by Simon Newcomb, an American astronomer, after he saw that the wear (and so the use) of the preferred first pages of logarithms tables (at this time there we compiled into books). Frank Benford, around 11938 (holocene calendar) remarked at his turn this unequal wear, believing he was the first to formulate this law that unduly bears his name today and arrived at the same results after having listed tens of thousands of data (lengths of rivers , stock quotes, etc.).

There is also one possible explanation: we need more often to extract the logarithm of numbers starting with 1 that numbers starting with 9, implying that the first are in "bigger quantity" than the second one.

Although this idea may seem to him quite implausible, Benford began to test his hypothesis. Nothing more simple: he studies tables of numerical values and calculates the percentage of occurrence of the left-most digit (first decimal). The results obtained confirm his intuition:

First position number	1	2	3	4	5	6	7	8	9
Apparition probability (%)	30.1	17.6	12.5	9.7	7.9	6.7	5.8	5.1	4.6

Table 5.44: **Occurrence of a digit following the Benford distribution**

From these data, Benford found experimentally that the cumulative probability of a number beginning with the digit n (except 0) is (we will prove this later) is given by the relation:

$$P(n)=\log_{10}\left(1+\frac{1}{n}\right) \tag{5.7.1134}$$

named "Benford distribution" (or "Benford law").

Here is a Maple™ plot of the previous function:

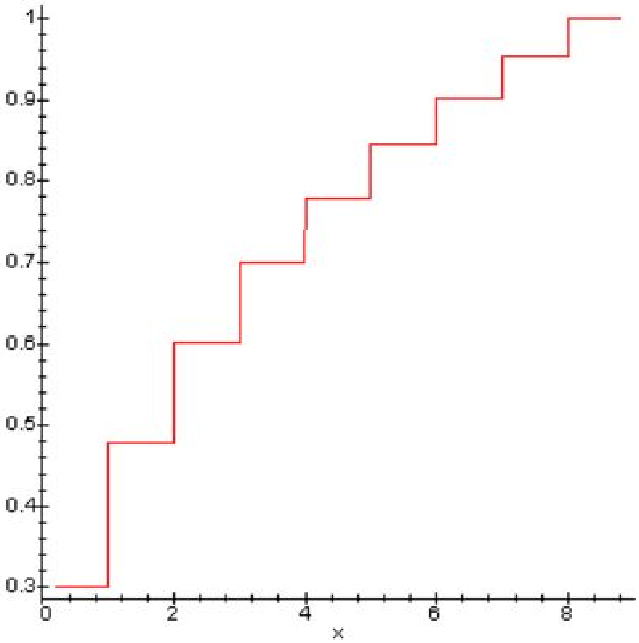

Figure 5.152: **Plot of the Benford function (cumulative distribution function)**

It should be noted that this distribution applies only to lists of values that are "natural", that is to say numbers with physical meaning. It obviously does not work on a list of numbers randomly drawn.

The Benford distribution has been tested on all kinds of tables: length of the rivers of the world, country area, election results, price list of grocery store ... It is true almost every time.

The distribution is said to be independent of the selected unit. If we take for example a supermarket price list , it also works well with the costs expressed in dollars as with the same costs converted into Euros.

This strange phenomenon remained unexplained and little studied until quite recently. Then a general proof was given in 11996 (holocene calendar), which uses the central limit theorem.

As surprising as it may seem, this distribution has found application: it is said that the IRS use it to detect false statements. The principle is based on the restriction seen above: Benford's distributions applies only to values with physical meaning.

Thus, if there is a universal probability distribution $P(n)$ on such numbers, they should be invariant under scaling such that:

$$P(kn)=f(k)P(n) \tag{5.7.1135}$$

If:

$$\int P(n)\mathrm{d}n=1 \tag{5.7.1136}$$

Then:

$$\int P(kn)\mathrm{d}n=\frac{1}{k} \tag{5.7.1137}$$

and the normalization of the distribution gives:

$$f(k)=\frac{1}{k} \tag{5.7.1138}$$

If we derive $P(kn)=f(k)P(n)$ with respect to k we obtain:

$$\frac{\mathrm{d}}{\mathrm{d}k}P(kn)=\frac{\mathrm{d}}{\mathrm{d}k}\frac{1}{k}P(n)\Rightarrow nP'(kn)=P(n)\frac{\mathrm{d}}{\mathrm{d}k}\frac{1}{k}\Rightarrow nP'(kn)=-P(n)\frac{1}{k^2} \tag{5.7.1139}$$

choosing $k=1$ we have:

$$nP'(n)=-P(n) \tag{5.7.1140}$$

This differential equation has for solution:

$$P(n)=\frac{1}{n} \tag{5.7.1141}$$

This function is not strictly speaking a distribution function (it diverges) and secondly, the physics and human laws impose limits.

So we have to compare this distribution with respect to an arbitrary reference. Thus, if the decimal number studied contains power of 10 (10 in total: $0,1,2,3,4,5,6,7,9$) the probability that the first non-zero digit (decimal) is D is also given by:

$$P_D=\frac{\int\limits_D^{D+1}P(n)\mathrm{d}n}{\int\limits_1^{10}P(n)\mathrm{d}n} \tag{5.7.1142}$$

The limits of the integral are from 1 to 10 because the null value is prohibited.

The integral in the denominator gives:

$$\int\limits_0^{10}P(n)\mathrm{d}n=\int\limits_0^{10}\frac{1}{n}\mathrm{d}n=\ln(10)-\ln(1)=\ln(10) \tag{5.7.1143}$$

The integral in the numerator gives:

$$\int\limits_D^{D+1}P(n)\mathrm{d}n=\int\limits_D^{D+1}\frac{1}{n}\mathrm{d}n=\ln(D+1)-\ln(D)=\ln\left(\frac{D+1}{D}\right) \tag{5.7.1144}$$

Finally:

$$P_D=\frac{\ln\left(\dfrac{D+1}{D}\right)}{\ln(10)}=\frac{\ln\left(1+\dfrac{1}{D}\right)}{\ln(10)} \tag{5.7.1145}$$

By the properties of logarithms (see section Functional Analysis page 2284) we have:

$$\boxed{P_D=\log_{10}\left(1+\frac{1}{D}\right)} \tag{5.7.1146}$$

However, the Benford's distribution applies not only to non-scaling data but also to numbers from any sources. Explain this case involves a more rigorous investigation using the central limit theorem. This demonstration was conducted only in 11996 (holocene calendar) by T. Hill by an approach using the distribution of distributions.

5.7.6.24 ex-Gaussian distribution

In probability theory, an "exponentially modified Gaussian distribution" (EMG, also known as "exGaussian distribution") describes the sum of independent Normal and exponential random variables. An exGaussian random variable Z may be expressed as $Z = X + Y$, where X and Y are independent, X is Gaussian with mean μ and variance σ^2 and Y is exponential of rate λ. It has a characteristic positive skew from the exponential component.

It may also be regarded as a weighted function of a shifted exponential with the weight being a function of the Normal distribution.

Remark

The distribution is used as a theoretical model for the shape of chromatographic peaks. It has been proposed as a statistical model of intermitotic time in dividing cells. It is also used in modelling cluster ion beams. It is commonly used in psychology and other brain sciences in the study of response times In a slight variant where the mean of the Normal component is set to zero, it is also used in Stochastic Frontier Analysis, as one of the distributional specifications for the composed error term that models inefficiency. In signal processing, EMGs have been extended to the multimodal case with an optional oscillation term to represent digitized sound signals.

More technically, let A be a random variable that is Normally distributed with mean μ and variance σ^2, and let B be a random variable that is exponentially distributed with rate λ. Suppose further that A and B are independent. Then the sum $X = A + B$ is said to have an exponentially-modified Gaussian (i.e., ex-Gaussian) distribution, with parameters μ, σ, and λ; that is:

$$X \sim \text{ex-Gaussian}(\mu, \sigma, \lambda) \tag{5.7.1147}$$

where $\mu \in \mathbb{R}, \sigma > 0$, and $\lambda > 0$.

The probability density function of X is:

$$\boxed{\text{ex-Gaussian}(\mu, \sigma, \lambda) = \frac{\lambda}{\sqrt{2\pi}} \exp\left[\frac{\lambda^2\sigma^2}{2} - \lambda(t-\mu)\right] \cdot \int\limits_{-\infty}^{\frac{t-\mu}{\sigma}-\lambda\sigma} \exp\left[-\frac{1}{2}y^2\right] \mathrm{d}y} \tag{5.7.1148}$$

Indeed, suppose X follows an ex-Gaussian distribution. Then $X = A + B$, where A and B are independent A is normally distributed with mean μ and variance σ^2, and B is exponentially distributed with rate λ. Then, the probability density function for A is given by:

$$f_A(t) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{1}{2}\left(\frac{t-\mu}{\sigma}\right)^2\right] \tag{5.7.1149}$$

and the probability density function for B is given by:

$$f_B(t) = \begin{cases} \lambda \exp[-\lambda t], \text{ if } t \geq 0 \\ 0, \text{ if } t < 0 \end{cases} \tag{5.7.1150}$$

Thus, the probability density function for the sum $X = A+B$ is given by taking the convolution of f_A and f_B :

$$\begin{aligned} f_X(t) &= \int_{-\infty}^{+\infty} f_A(x) f_B(t-x)\mathrm{d}x \\ &= \int_{-\infty}^{t} f_A(x) f_B(t-x)dx + \int_{t}^{\infty} f_A(x) f_B(t-x)\mathrm{d}x \\ &= \int_{-\infty}^{t} f_A(x) f_B(t-x)\mathrm{d}x \end{aligned} \tag{5.7.1151}$$

which follows from the fact that $f_B(t-x) = 0$ for $x > t$. From here, we substitute these expressions for the probability density functions f_A and f_B:

$$\begin{aligned} f_X(t) &= \int_{-\infty}^{t} \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \cdot \lambda \exp[-\lambda(t-x)]\mathrm{d}x \\ &= \frac{\lambda}{\sigma\sqrt{2\pi}} \int_{-\infty}^{t} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \cdot \exp[-\lambda t + \lambda x]\mathrm{d}x \\ &= \frac{\lambda}{\sigma\sqrt{2\pi}} \int_{-\infty}^{t} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \cdot \exp[-\lambda t] \cdot \exp[\lambda x]\mathrm{d}x \\ &= \frac{\lambda \exp[-\lambda t]}{\sigma\sqrt{2\pi}} \int_{-\infty}^{t} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2 + \lambda x\right] \mathrm{d}x \end{aligned} \tag{5.7.1152}$$

We can further simplify the integrand with a substitution; to this end, let:

$$y = \frac{x-\mu}{\sigma} - \lambda\sigma \tag{5.7.1153}$$

This gives the following three identities:

$$\frac{\mathrm{d}y}{\mathrm{d}x} = \frac{1}{\sigma}, \qquad \text{or equivalently,} \qquad \mathrm{d}x = \sigma\mathrm{d}y \tag{5.7.1154}$$

and:

$$\frac{x-\mu}{\sigma} = y + \lambda\sigma \tag{5.7.1155}$$

and:

$$x = y\sigma + \lambda\sigma^2 + \mu \tag{5.7.1156}$$

Substituting these identities into:

$$f_X(t) = \frac{\lambda \exp[-\lambda t]}{\sigma\sqrt{2\pi}} \int_{-\infty}^{t} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2 + \lambda x\right] \mathrm{d}x \tag{5.7.1157}$$

gives:

$$\begin{aligned}
f_X(t) &= \frac{\lambda\exp[-\lambda t]}{\sigma\sqrt{2\pi}} \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}(y+\lambda\sigma)^2+\lambda\left(y\sigma+\lambda\sigma^2+\mu\right)\right]\sigma\mathrm{d}y\\
&= \frac{\lambda\sigma\exp[-\lambda t]}{\sigma\sqrt{2\pi}} \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}\left(y^2+2y\lambda\sigma+\lambda^2\sigma^2\right)+\lambda y\sigma+\lambda^2\sigma^2+\lambda\mu\right]\mathrm{d}y\\
&= \frac{\lambda\exp[-\lambda t]}{\sqrt{2\pi}} \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}y^2-y\lambda\sigma-\frac{\lambda^2\sigma^2}{2}+\lambda y\sigma+\lambda^2\sigma^2+\lambda\mu\right]dy\\
&= \frac{\lambda\exp[-\lambda t]}{\sqrt{2\pi}} \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}y^2\right]\cdot\exp\left[\frac{\lambda^2\sigma^2}{2}+\lambda\mu\right]\mathrm{d}y\\
&= \frac{\lambda\exp[-\lambda t]}{\sqrt{2\pi}}\cdot\exp\left[\frac{\lambda^2\sigma^2}{2}+\lambda\mu\right] \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}y^2\right]\cdot\mathrm{d}y\\
&= \frac{\lambda}{\sqrt{2\pi}}\cdot\exp\left[-\lambda t+\frac{\lambda^2\sigma^2}{2}+\lambda\mu\right] \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}y^2\right]\mathrm{d}y\\
&= \frac{\lambda}{\sqrt{2\pi}}\cdot\exp\left[\frac{\lambda^2\sigma^2}{2}-\lambda(t-\mu)\right] \int\limits_{-\infty}^{\frac{x-\mu}{\sigma}+\lambda\sigma} \exp\left[-\frac{1}{2}y^2\right]\mathrm{d}y
\end{aligned} \tag{5.7.1158}$$

and this finishes the proof!

Let X still be a random variable following an ex-Gaussian distribution:

$$X \sim \text{ex-Gaussian}(\mu,\sigma,\lambda) \tag{5.7.1159}$$

Then, the mean or expected value of X is:

$$\mathrm{E}(X) = \mu + \frac{1}{\lambda} \tag{5.7.1160}$$

The mean or expected value $\mathrm{E}(X)$ is the first raw moment of X, so we can use the moment-generating function of the ex-Gaussian distribution to calculate (see page 933):

$$\mathrm{E}(X) = M_X'(0) \tag{5.7.1161}$$

First, we differentiate:

$$M_X(t) = \left(\frac{\lambda}{\lambda-t}\right)\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right] \tag{5.7.1162}$$

with respect to t. Using the product rule and chain rule gives:

$$\begin{aligned}M_X'(t) &= \frac{\lambda}{(\lambda-t)^2}\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right]+\left(\frac{\lambda}{\lambda-t}\right)\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right](\mu+\sigma^2t)\\ &=\left(\frac{\lambda}{\lambda-t}\right)\cdot\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right]\cdot\left[\frac{1}{\lambda-t}+\mu+\sigma^2t\right]\end{aligned}\tag{5.7.1163}$$

Evaluating the latter at $t=0$ gives the desired result:

$$\begin{aligned}M_X'(0) &= \left(\frac{\lambda}{\lambda-0}\right)\cdot\exp\left[\mu\cdot 0+\frac{1}{2}\sigma^2\cdot 0^2\right]\cdot\left[\frac{1}{\lambda-0}+\mu+\sigma^2\cdot 0\right]\\ &=1\cdot 1\cdot\left[\frac{1}{\lambda}+\mu\right]\\ &=\mu+\frac{1}{\lambda}\end{aligned}\tag{5.7.1164}$$

Let X be a random variable following an ex-Gaussian distribution:

$$X\sim\text{ex-Gaussian}(\mu,\sigma,\lambda)\tag{5.7.1165}$$

Then the variance of X is:

$$\mathrm{V}(X)=\sigma^2+\frac{1}{\lambda^2}\tag{5.7.1166}$$

To compute the variance of X, we partition the variance into expected values using Huygens relation (see page 593):

$$\mathrm{V}(X)=\mathrm{E}\left(X^2\right)-\mathrm{E}(X)^2\tag{5.7.1167}$$

We then use the moment-generating function of the ex-Gaussian distribution to calculate:

$$M_X(t)=\left(\frac{\lambda}{\lambda-t}\right)\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right]\tag{5.7.1168}$$

with respect to t. Using the product rule and chain rule gives:

$$\begin{aligned}M_X'(t) &= \frac{\lambda}{(\lambda-t)^2}\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right]+\left(\frac{\lambda}{\lambda-t}\right)\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right](\mu+\sigma^2t)\\ &=\left(\frac{\lambda}{\lambda-t}\right)\cdot\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right]\cdot\left[\frac{1}{\lambda-t}+\mu+\sigma^2t\right]\\ &=M_X(t)\cdot\left[\frac{1}{\lambda-t}+\mu+\sigma^2t\right]\end{aligned}\tag{5.7.1169}$$

We now use the product rule to obtain the second derivative:

$$\begin{aligned}M_X''(t) &= M_X'(t)\cdot\left[\frac{1}{\lambda-t}+\mu+\sigma^2t\right]+M_X(t)\cdot\left[\frac{1}{(\lambda-t)^2}+\sigma^2\right]\\ &=M_X(t)\cdot\left[\frac{1}{\lambda-t}+\mu+\sigma^2t\right]^2+M_X(t)\cdot\left[\frac{1}{(\lambda-t)^2}+\sigma^2\right]\\ &=M_X(t)\cdot\left[\left(\frac{1}{\lambda-t}+\mu+\sigma^2t\right)^2+\frac{1}{(\lambda-t)^2}+\sigma^2\right]\\ &=\left(\frac{\lambda}{\lambda-t}\right)\cdot\exp\left[\mu t+\frac{1}{2}\sigma^2t^2\right]\cdot\left[\left(\frac{1}{\lambda-t}+\mu+\sigma^2t\right)^2+\frac{1}{(\lambda-t)^2}+\sigma^2\right]\end{aligned}\tag{5.7.1170}$$

Applying:

$$\mathrm{E}\left(X^2\right)=M''_X(0) \qquad (5.7.1171)$$

gives:

$$\begin{aligned}\mathrm{E}\left(X^2\right)&=M''_X(0)\\&=\left(\dfrac{\lambda}{\lambda-0}\right)\cdot\exp\left[\mu\cdot 0+\dfrac{1}{2}\sigma^2\cdot 0^2\right]\cdot\left[\left(\dfrac{1}{\lambda-0}+\mu+\sigma^2\cdot 0\right)^2+\dfrac{1}{(\lambda-0)^2}+\sigma^2\right]\\&=1\cdot 1\cdot\left[\left(\dfrac{1}{\lambda}+\mu\right)^2+\dfrac{1}{\lambda^2}+\sigma^2\right]\\&=\dfrac{1}{\lambda^2}+\dfrac{2\mu}{\lambda}+\mu^2+\dfrac{1}{\lambda^2}+\sigma^2=\dfrac{2}{\lambda^2}+\dfrac{2\mu}{\lambda}+\mu^2+\sigma^2\end{aligned} \qquad (5.7.1172)$$

Since the mean of an ex-Gaussian distribution is given by:

$$\mathrm{E}(X)=\mu+\frac{1}{\lambda} \qquad (5.7.1173)$$

we can apply the Huygens relation to show:

$$\begin{aligned}\mathrm{V}(X)&=\mathrm{E}\left(X^2\right)-\mathrm{E}(X)^2\\&=\left[\dfrac{2}{\lambda^2}+\dfrac{2\mu}{\lambda}+\mu^2+\sigma^2\right]-\left(\mu+\dfrac{1}{\lambda}\right)^2\\&=\dfrac{2}{\lambda^2}+\dfrac{2\mu}{\lambda}+\mu^2+\sigma^2-\mu^2-\dfrac{2\mu}{\lambda}-\dfrac{1}{\lambda^2}\\&=\sigma^2+\dfrac{1}{\lambda^2}\end{aligned} \qquad (5.7.1174)$$

and this completes the proof.

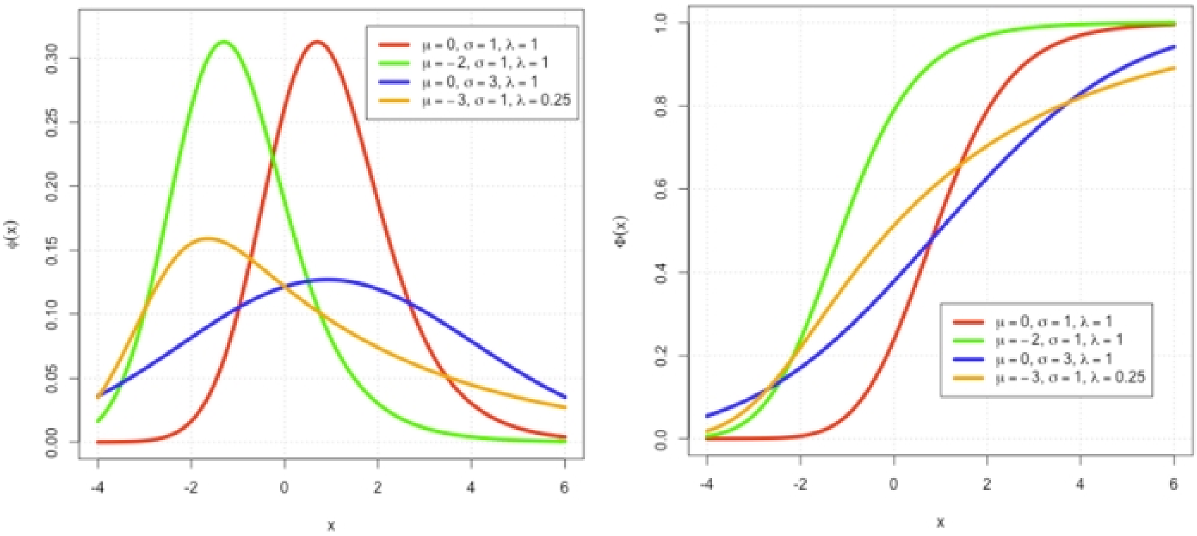

Figure 5.153: ex-Gaussian law (mass and cumulative distribution function)

Let X still be a random variable following an ex-Gaussian distribution:

$$X \sim \text{ ex-Gaussian } (\mu, \sigma, \lambda) \tag{5.7.1175}$$

Then the skewness of X is:

$$\text{Skew}(X) = \gamma_1 = \frac{2}{\lambda^3 \left(\sigma^2 + \frac{1}{\lambda^2}\right)^{\frac{3}{2}}} \tag{5.7.1176}$$

Indeed, remember first that the Fisher-Pearson coefficient of skewness is defined by (see page **??**):

$$\gamma_1 = \frac{\text{E}\left(X^3\right) - 3\mu\sigma^2 - \mu^3}{\sigma^3} \tag{5.7.1177}$$

where μ and σ are the mean and standard deviation of X, respectively. To prevent confusion between the labels used for the ex-Gaussian parameters and the mean and standard deviation of X, we rewrite the above relation as:

$$\gamma_1 = \frac{\text{E}\left(X^3\right) - 3 \cdot \text{E}(X) \cdot \text{V}(X) - \text{E}(X)^3}{\text{V}(X)^{\frac{3}{2}}} \tag{5.7.1178}$$

Since X follows an ex-Gaussian distribution, the mean of X is given by:

$$\text{E}(X) = \mu + \frac{1}{\lambda} \tag{5.7.1179}$$

and the variance by:

$$\text{V}(X) = \sigma^2 + \frac{1}{\lambda^2} \tag{5.7.1180}$$

Thus, the primary work is to compute $\text{E}\left(X^3\right)$. To do this, we use again the moment-generating function of the ex-Gaussian distribution to calculate:

$$\text{E}\left(X^3\right) = M_X'''(0) \tag{5.7.1181}$$

based on the relationship between raw moment and moment-generating function. First, we differentiate the moment-generating function of the ex-Gaussian distribution:

$$\begin{aligned} M_X'(t) &= \frac{\lambda}{(\lambda - t)^2} \exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right] + \left(\frac{\lambda}{\lambda - t}\right) \exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right] \left(\mu + \sigma^2 t\right) \\ &= \left(\frac{\lambda}{\lambda - t}\right) \cdot \exp\left[\mu t + \frac{1}{2}\sigma^2 t^2\right] \cdot \left[\frac{1}{\lambda - t} + \mu + \sigma^2 t\right] \\ &= M_X(t) \cdot \left[\frac{1}{\lambda - t} + \mu + \sigma^2 t\right] \end{aligned} \tag{5.7.1182}$$

We then use the product rule to obtain the second derivative:

$$\begin{aligned} M_X''(t) &= M_X'(t) \cdot \left[\frac{1}{\lambda - t} + \mu + \sigma^2 t\right] + M_X(t) \cdot \left[\frac{1}{(\lambda - t)^2} + \sigma^2\right] \\ &= M_X(t) \cdot \left[\frac{1}{\lambda - t} + \mu + \sigma^2 t\right]^2 + M_X(t) \cdot \left[\frac{1}{(\lambda - t)^2} + \sigma^2\right] \\ &= M_X(t) \cdot \left[\left(\frac{1}{\lambda - t} + \mu + \sigma^2 t\right)^2 + \frac{1}{(\lambda - t)^2} + \sigma^2\right] \end{aligned} \tag{5.7.1183}$$

Finally, we use the product rule and chain rule to obtain the third derivative:

$$\begin{aligned}M_X'''(t)&=M_X'(t)\left[\left(\frac{1}{\lambda-t}+\mu+\sigma^2t\right)^2+\frac{1}{(\lambda-t)^2}+\sigma^2\right]\\&\quad+M_X(t)\left[2\left(\frac{1}{\lambda-t}+\mu+\sigma^2t\right)\left(\frac{1}{(\lambda-t)^2}+\sigma^2\right)+\frac{2}{(\lambda-t)^3}\right]\end{aligned} \tag{5.7.1184}$$

Applying:

$$\mathrm{E}\left(X^3\right)=M_X'''(0) \tag{5.7.1185}$$

Into the previous relation, we get:

$$\begin{aligned}\mathrm{E}\left(X^3\right)&=M_X'''(0)\\&=M_X'(0)\left[\left(\frac{1}{\lambda}+\mu\right)^2+\frac{1}{\lambda^2}+\sigma^2\right]+M_X(0)\left[2\left(\frac{1}{\lambda}+\mu\right)\left(\frac{1}{\lambda^2}+\sigma^2\right)+\frac{2}{\lambda^3}\right]\\&=\left(\mu+\frac{1}{\lambda}\right)\left(\frac{1}{\lambda^2}+\frac{2\mu}{\lambda}+\mu^2+\frac{1}{\lambda^2}+\sigma^2\right)+\left(\frac{2}{\lambda^3}+\frac{2\sigma^2}{\lambda}+\frac{2\mu}{\lambda^2}+2\mu\sigma^2+\frac{2}{\lambda^3}\right)\\&=\left(\mu+\frac{1}{\lambda}\right)\left(\frac{2}{\lambda^2}+\frac{2\mu}{\lambda}+\mu^2+\sigma^2\right)+\left(\frac{4}{\lambda^3}+\frac{2\sigma^2}{\lambda}+\frac{2\mu}{\lambda^2}+2\mu\sigma^2\right)\\&=\frac{2\mu}{\lambda^2}+\frac{2\mu^2}{\lambda}+\mu^3+\mu\sigma^2+\frac{2}{\lambda^3}+\frac{2\mu}{\lambda^2}+\frac{\mu^2}{\lambda}+\frac{\sigma^2}{\lambda}+\frac{4}{\lambda^3}+\frac{2\sigma^2}{\lambda}+\frac{2\mu}{\lambda^2}+2\mu\sigma^2\\&=\frac{6\mu}{\lambda^2}+\frac{6}{\lambda^3}+\frac{3\mu^2+3\sigma^2}{\lambda}+3\mu\sigma^2+\mu^3\end{aligned} \tag{5.7.1186}$$

We now substitute the previous results:

$$\begin{aligned}\mathrm{E}(X)&=\mu+\frac{1}{\lambda}\\\mathrm{V}(X)&=\sigma^2+\frac{1}{\lambda^2}\\\mathrm{E}\left(X^3\right)&=M_X'''(0)=\frac{6\mu}{\lambda^2}+\frac{6}{\lambda^3}+\frac{3\mu^2+3\sigma^2}{\lambda}+3\mu\sigma^2+\mu^3\end{aligned} \tag{5.7.1187}$$

Into the numerator of:

$$\text{Skew}(X)=\gamma_1=\frac{\mathrm{E}\left(X^3\right)-3\cdot\mathrm{E}(X)\cdot\mathrm{V}(X)-\mathrm{E}(X)^3}{\mathrm{V}(X)^{\frac{3}{2}}} \tag{5.7.1188}$$

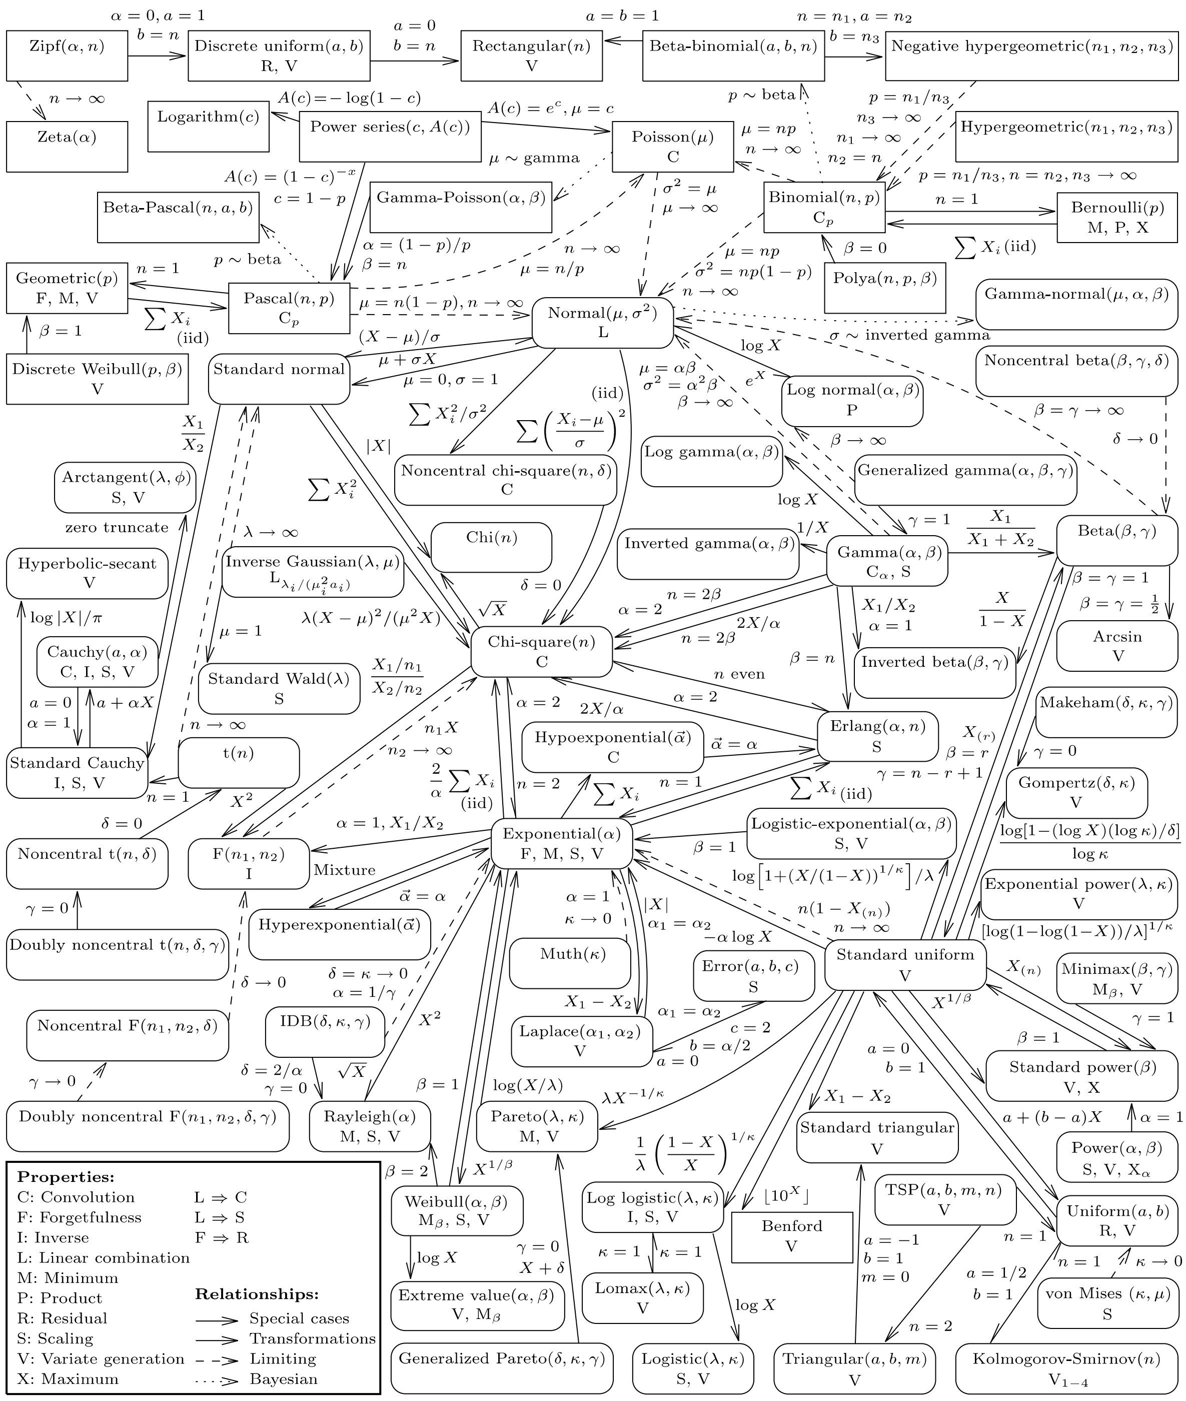
Gives:

$$\begin{aligned}\mathrm{E}\left(X^3\right)-3\cdot\mathrm{E}(X)\cdot\mathrm{V}(X)-\mathrm{E}(X)^3&=\left(\frac{6\mu}{\lambda^2}+\frac{6}{\lambda^3}+\frac{3\mu^2+3\sigma^2}{\lambda}+3\mu\sigma^2+\mu^3\right)-3\left(\mu+\frac{1}{\lambda}\right)\left(\sigma^2+\frac{1}{\lambda^2}\right)-\left(\mu+\frac{1}{\lambda}\right)^3\\&=\frac{6\mu}{\lambda^2}+\frac{6}{\lambda^3}+\frac{3\mu^2+3\sigma^2}{\lambda}+3\mu\sigma^2+\mu^3-3\mu\sigma^2-\frac{3\mu}{\lambda^2}-\frac{3\sigma^2}{\lambda}-\frac{3}{\lambda^3}-\mu^3-\frac{3\mu^2}{\lambda}-\frac{3\mu}{\lambda^2}-\frac{1}{\lambda^3}\\&=\frac{2}{\lambda^3}\end{aligned} \tag{5.7.1189}$$

Thus, we have:

$$\begin{aligned}
\text{Skew}(X)=\gamma_1&=\frac{\mathrm{E}\left(X^3\right)-3\cdot\mathrm{E}(X)\cdot\mathrm{V}(X)-\mathrm{E}(X)^3}{\mathrm{V}(X)^{\frac{3}{2}}}\\
&=\frac{\frac{2}{\lambda^3}}{\left(\sigma^2+\frac{1}{\lambda^2}\right)^{\frac{3}{2}}}\\
&=\frac{2}{\lambda^3\left(\sigma^2+\frac{1}{\lambda^2}\right)^{\frac{3}{2}}}.
\end{aligned} \tag{5.7.1190}$$

To summarize an important part of everything we've seen so far, the picture below is very useful because it summarizes the relation between 76 of the most common univariate distributions (57 continuous and 19 discrete):



Zipf(α, n)
Discrete uniform(a, b) R, V
Rectangular(n) V
Beta-binomial(a, b, n)
Negative hypergeometric(n₁, n₂, n₃)
Zeta(α)
Logarithm(c)
Power series(c, A(c))
Poisson(μ) C
Hypergeometric(n₁, n₂, n₃)
Beta-Pascal(n, a, b)
Gamma-Poisson(α, β)
Binomial(n, p) Cₚ
Bernoulli(p) M, P, X
Geometric(p) F, M, V
Pascal(n, p) Cₚ
Normal(μ, σ²) L
Polya(n, p, β)
Gamma-normal(μ, α, β)
Discrete Weibull(p, β) V
Standard normal
Noncentral beta(β, γ, δ)
Log normal(α, β) P
Noncentral chi-square(n, δ) C

5.7.7 Likelihood Estimators

What follows is of extreme importance in the field of statistics and is used widely in practice. It is important therefore to pay attention! Besides the fact that we will use massively likelihood estimators in this chapter, we shall find it in the chapter of Numerical Methods for advanced and generalized linear regression (including their generalization that are M-estimators or even W-estimators!) and also in the chapter of Industrial Engineering in the context of parametric estimation of reliability.

We assume that we have observations $x_1, x_2, x_3, \ldots, x_n$ which are realizations of unbiased independent random variables (in the sense that they are randomly selected from a batch) $X_1, X_2, X_3, \ldots, X_n$ of a unknown probability distribution but having the same one.

Suppose we proceed by trial and error to estimate the unknown probability distribution P. One way to proceed is to ask if the observations $x_1, x_2, x_3, \ldots, x_n$ had a high probability to get out or not with this arbitrary probability distribution P.

We need for this to calculate the joint probability that the observations $x_1, x_2, x_3, \ldots, x_n$ had to get out with the probabilities $p_1, p_2, p_3, \ldots, p_n$. This joint probability is equal to (see section Probabilities page 480):

$$\prod_{i=1}^{n} P(X_i = x_i) \tag{5.7.1191}$$

noting by the letter P the assumed probability distribution associated to $p_1, p_2, p_3, \ldots, p_n$. You must admit that it would be particularly awkward, at the intuition level of risk, to choose a probability distribution (with its parameters!) that minimizes this quantity...

Instead, we will seek the probabilities $p_1, p_2, p_3, \ldots, p_n$ (or the associated parameters of the probability distribution) that maximizes $\prod_{i=1}^{n} P(X_i = x_i)$, that is to say, that makes the observations $x_1, x_2, x_3, \ldots, x_n$ the most likely possible.

This leads us to seek the parameter(s) θ that maximizes the quantity:

$$L_n(\theta) = \prod_{i=1}^{n} P_\theta(X_i = x_i) \tag{5.7.1192}$$

and where the parameter θ is often in undergraduate school level problems a first order moment (mean) or second order moment (variance).

The quantity L is named "likelihood". It is a function of the parameter(s) θ and observations θ.

The value(s) of the parameter(s) θ that maximize the likelihood $L_n(\theta)$ are named "maximum likelihood estimators" (MLE estimators).

In the very special case but useful of the Normal distribution, one of the parameters θ will be the variance (see a little further concrete example) and can be considered intuitive to the physicist that to maximize the probability, the standard deviation should be as small as possible (so that the maximum numbers of events are in the same interval). Thus, when we calculate a MLE which is the smallest among several possible, then we are talking about a UMV estimator for "Uniform Minimum Variance Unbiased" because their own variance should be as small as possible. This can be demonstrated (but the proof is not very elegant) using the definition of the Fisher Information and the Fréchet theorem (or Rao-Cramér) that makes use of the Cauchy-Schwarz inequality (see section Vector Calculus page 1826) and the analogy between mean and scalar product ... This demonstration will not be in this textbook.

Let us still do seven small examples (very classic, useful and important in the industry) with in order of importance (i.e. not necessarily in order of ease...) the distribution function of Gauss-Laplace (Normal distribution), the Poisson distribution, the binomial distribution, the Geometric distribution, the Weibull distribution, the Gamma distribution and finally the Pareto distribution.

Remarks

R1. These seven examples are important as used in SPC (statistical process control) in various international companies around the world (see section Industrial Engineering page 8673).

R2. A frequentist maximum likelihood estimate is like to the "mode" of the likelihood function, so in a Bayesian context with uniform prior, the MLE is like a mode of the posterior.

R3. In Bayesian statistics (see further below) we have the "maximum a posteriori" (MAP) which finds a maximum of the posterior distribution for a uniform prior probability. The MAP estimator coincides with the maximum-likelihood estimator.

5.7.7.1 Normal Distribution MLE

Let be $x_1, x_2, \ldots, x_n$ an n-sample of identically distributed random variables assumed to follow a Gaussian-Laplace (Normal) distribution of parameters μ and σ^2.

We are looking what are the values of the maximum likelihood estimators $\vec{\theta}$ that maximize the likelihood $L_n(\theta)$ of the Normal distribution?

Remark

It is trivial that the maximum likelihood estimators vector is here:

$$\vec{\theta} = (\mu, \sigma) \tag{5.7.1193}$$

We have proved earlier above that the density of a Gaussian random variable was given by:

$$P(x, \mu, \mu) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \tag{5.7.1194}$$

The likelihood is then given by:

$$L(\mu, \sigma) = \prod_{i=1}^{n} P(x_i, \mu, \mu) = \frac{1}{\sigma^n \sqrt{2\pi}^n} e^{-\frac{1}{2\sigma^2}\sum_{i=1}^{n}(x_i-\mu)^2} \tag{5.7.1195}$$

Maximize a function or maximize its logarithm is equivalent, therefore the "log-likelihood" will be:

$$\ln(L(\mu,\sigma)) = -\frac{n}{2}\ln(2\pi) - n\ln(\sigma) - \frac{1}{2\sigma^2}\sum_{i=1}^{n}(x_i-\mu)^2 \tag{5.7.1196}$$

To determine the two estimators of the Normal distribution, first let us fix the standard deviation. To do this, we derive $\ln(L(\mu,\sigma))$ over μ and look for what the average value of the function is equal to zero.

Remark

The partial derivative that we seek to cancel is often named the "score function" (we will often find this concept during our study of optimization techniques and machine learning in the chapter of Theoretical Computing):

$$\frac{\partial}{\partial\theta}\ln\left[L(\theta)\right] \tag{5.7.1197}$$

It remains after simplification the following term that is equal to zero:

$$\sum_{i=1}^{n}(x_i-\mu)^2 \tag{5.7.1198}$$

Thus, the maximum likelihood estimator of the expected mean of the Normal distribution is after rearrangement:

$$\boxed{\hat{\mu} = \frac{1}{n}\sum_{i=1}^{n}x_i} \tag{5.7.1199}$$

and we see that it is simply the arithmetic mean (or also named "sample mean").

Let us now fix the mean. The cancellation of the derivative of $\ln(L(\mu,\sigma))$ over σ leads us to:

$$\frac{\partial}{\partial\sigma}\ln(L(\mu,\sigma)) = -\frac{n}{\sigma^2} - \frac{1}{\sigma^3}\sum_{i=1}^{n}(x_i-\mu)^2 = 0 \tag{5.7.1200}$$

This allows us to write the maximum likelihood estimator for the standard deviation (the variance when the mean is known under the an assumed distribution also supposed known!):

$$\boxed{\hat{\sigma} = \frac{1}{n}\sum_{i=1}^{n}(x_i-\mu)^2} \tag{5.7.1201}$$

that some people also name "Pearson standard deviation"...

Even if it is a little bit redundant some people asked us to show the proof of the estimator of the covariance matrix (and therefore the correlation matrix).

Remember that we have proved earlier that for the bivariate case we have:

$$f(X_1,X_2) = \frac{1}{2\pi|\Sigma|^{1/2}}e^{-\frac{1}{2}\overrightarrow{(x-\mu)}^T\Sigma^{-1}\overrightarrow{(x-\mu)}} \tag{5.7.1202}$$

In fact the relation is the same for the multivariate case with T!

The log-likelihood is therefore immediate by analogy with the univariate case:

$$\ln\left(L(\vec{\mu},\Sigma)\right)=-\frac{nT}{2}\ln(2\pi)-\frac{T}{2}\ln(\Sigma)-\frac{1}{2}\sum_{i=1}^{T}(x_i-\mu)^T\Sigma^{-1}(x_i-\mu) \tag{5.7.1203}$$

That we can also write (as Σ is diagonal and Σ^{-1} also):

$$\begin{aligned}\ln\left(L(\vec{\mu},\Sigma)\right)&=-\frac{nT}{2}\ln(2\pi)-\frac{T}{2}\ln(\Sigma)-\frac{1}{2}\sum_{i=1}^{T}\text{tr}\left((x_i-\mu)^T\Sigma^{-1}(x_i-\mu)\right)\\&=-\frac{nT}{2}\ln(2\pi)-\frac{T}{2}\ln(\Sigma)-\frac{1}{2}\sum_{i=1}^{T}\text{tr}\left(\Sigma^{-1}(x_i-\mu)^T(x_i-\mu)\right)\\&:=-\frac{nT}{2}\ln(2\pi)-\frac{T}{2}\ln(\Sigma)-\frac{1}{2}\text{tr}\left(\Sigma^{-1}S\right)\end{aligned} \tag{5.7.1204}$$

Where by definition and using the estimator of the mean:

$$S=\sum_{i=1}^{T}(x_i-\hat{\mu})^T(x_i-\hat{\mu}) \tag{5.7.1205}$$

Then we deduce that:

$$\frac{\partial}{\partial\Sigma^{-1}}\ln\left(L(\vec{\hat{\mu}},\Sigma)\right)=\frac{T}{2}\Sigma-\frac{1}{2}\Sigma=0 \tag{5.7.1206}$$

and we get finally:

$$\hat{\Sigma}=\frac{1}{T}S \tag{5.7.1207}$$

However, we have not yet defined what is a good estimator! What we mean here is:

- If the mean of an estimator is equal to itself, we say that this estimator is "unbiased" and that's obviously what we want!
- If the mean of an estimator is not equal to itself, then we say that this estimator is "biased" and is necessarily less good...

In the previous example, the average is unbiased (this is trivial as the average of the arithmetic mean is equal to itself). But what about the variance (verbatim the standard deviation)?

A simple little calculation by linearity of the mean (since the random variables are identically distributed) will give us the answer in the case where the theoretical average (mean) is approximated as in practice (industry) by the estimator of the mean (most common case).

So we have for the calculation of the mean of the "sample variance":

$$\begin{aligned}\mathrm{E}(\hat{\sigma}^2)&=\mathrm{E}(\mathrm{V}(X))=\mathrm{E}\left(\frac{1}{n}\sum_{i=1}^{n}(x_i-\mu)^2\right)=\mathrm{E}\left(\frac{1}{n}\sum_{i=1}^{n}(x_i^2-2x_i\hat{\mu}+\hat{\mu}^2)\right)\\&=\mathrm{E}\left(\frac{1}{n}\sum_{i=1}^{n}x_i^2-2\frac{1}{n}\sum_{i=1}^{n}x_i\hat{\mu}+\frac{1}{n}\sum_{i=1}^{n}\hat{\mu}^2)\right)=\mathrm{E}\left(\frac{1}{n}\sum_{i=1}^{n}x_i^2-2\hat{\mu}\frac{1}{n}\sum_{i=1}^{n}x_i+\frac{1}{n}n\hat{\mu}^2)\right)\\&=\mathrm{E}\left(\frac{1}{n}\sum_{i=1}^{n}x_i^2-2\hat{\mu}^2+\hat{\mu}^2)\right)=\mathrm{E}\left(\frac{1}{n}\sum_{i=1}^{n}x_i^2-2\hat{\mu})\right)=\frac{1}{n}\sum_{i=1}^{n}\mathrm{E}(x_i^2)-\mathrm{E}(\hat{\mu}^2)\end{aligned} \tag{5.7.1208}$$

However, as the variables are supposed to be identically distributed:

$$\mathrm{E}(\hat{\sigma}^2)=\frac{1}{n}\sum_{i=1}^{n}\mathrm{E}(x_i^2)-\mathrm{E}(\hat{\mu}^2)=\frac{1}{n}\sum_{i=1}^{n}\mathrm{E}(x^2)-\mathrm{E}(\hat{\mu}^2)=\mathrm{E}(x^2)-\mathrm{E}(\hat{\mu}^2) \tag{5.7.1209}$$

And as we have (Huygens theorem):

$$\begin{aligned}\mathrm{V}(X)&=\mathrm{E}(X^2)-\mathrm{E}(X^2)\\\mathrm{V}(\hat{\mu})&=\mathrm{E}(\hat{\mu}^2)-\mathrm{E}(\hat{\mu})^2=\mathrm{E}(\hat{\mu}^2)-\mathrm{E}(X)^2\end{aligned} \tag{5.7.1210}$$

wherein the second relation can be written only because we use the maximum likelihood estimator of the average (empirical average). Therefore combining the two above relations with the prior-previous one we get:

$$\mathrm{E}(\hat{\sigma}^2)=\mathrm{E}(x^2)-\mathrm{E}(\hat{\mu}^2)=\left(\mathrm{V}(X)+\mathrm{E}(X)^2\right)-\left(\mathrm{V}(\hat{\mu})+\mathrm{E}(X)^2\right)=\mathrm{V}(X)-\mathrm{V}(\hat{\mu}) \tag{5.7.1211}$$

and as:

$$\mathrm{V}(X)=\sigma^2\quad\text{and}\quad\mathrm{V}(\hat{\mu})=\frac{\sigma^2}{n} \tag{5.7.1212}$$

Finally we have:

$$\boxed{\mathrm{E}(\hat{\sigma}^2)=\sigma^2-\frac{\sigma^2}{n}=\left(1-\frac{1}{n}\right)\sigma^2=\frac{n-1}{n}\sigma^2} \tag{5.7.1213}$$

so we have a bias of at least one standard error:

$$-\frac{\sigma^2}{n} \tag{5.7.1214}$$

then we say that this estimator has a negative bias (it underestimates the true value!).

We also note that the estimator tends towards to an unbiased estimator of the variance (USV) when the number of items tends to infinity $n\rightarrow+\infty$. We say that we have a "asymptotically unbiased" or "asymptotically unbiased estimator".

Then, the "bias of an estimator" is defined, according to the special case above, in general as:

$$\boxed{\text{bias}(\hat{\theta})=\mathrm{E}(\hat{\theta})-\theta} \tag{5.7.1215}$$

It is important to note that we have yet proved that the empirical variance tends towards the theoretical variance when n tends to infinity and ... that the data follows or not a Normal distribution!

By the properties of the mean, we get now:

$$\mathrm{E}(\mathrm{E}(\hat{\sigma}^2)) = \mathrm{E}(\hat{\sigma}^2) = \mathrm{E}\left(\frac{n-1}{n}\sigma^2\right) \tag{5.7.1216}$$

We have then:

$$\sigma = \sqrt{\frac{n}{n-1}\hat{\sigma}^2} = \sqrt{\frac{n}{n-1}\frac{1}{n}\sum_{i=1}^{n}(x_i-\hat{\mu})^2} = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(x_i-\hat{\mu})^2} \tag{5.7.1217}$$

simply named the "standard deviation" ... (that must not be confused with the "standard error" as we shall see later).

An estimator is named "consistent estimator" if it converges in probability (as it can be considered itself as random variable following it own distribution), when $n \rightarrow +\infty$, towards the true parameter value. Technically, this condition will be written:

$$\boxed{\forall \varepsilon > 0 : \lim_{n\rightarrow+\infty} P\left(\left|\hat{\theta}-\theta\right| > \varepsilon\right) = 0} \tag{5.7.1218}$$

Maybe, the following example may help. Let's suppose the samples are taking from a Normal distribution. Then using the fact that $\frac{(n-1)S^2}{\sigma^2}$ (see page 860) is a chi-squared random variable with $n-1$ degrees of freedom, we get:

$$\begin{aligned} \mathrm{V}\left(\frac{(n-1)S^2}{\sigma^2}\right) &= \mathrm{Var}\ \chi^2_{n-1} \\ \frac{(n-1)^2}{\sigma^4}\mathrm{V}(S^2) &= 2(n-1) \\ \mathrm{V}(S^2) &= \frac{2(n-1)\sigma^4}{(n-1)^2} = \frac{2\sigma^4}{(n-1)}, \end{aligned} \tag{5.7.1219}$$

where we have used that fact that (see page 773):

$$\mathrm{V}\left(\chi^2_{n-1}\right) = 2(n-1) \tag{5.7.1220}$$

So written differently (according to above notation):

$$\boxed{\mathrm{V}\left(\hat{\sigma}^2\right) = \frac{2\sigma^2}{n-1}} \tag{5.7.1221}$$

From these facts we can informally see that the distribution of $\mathrm{V}\left(\hat{\sigma}^2\right)$ is becoming more and more concentrated at σ^2 as the sample size increases since the mean $\mathrm{E}\left(\hat{\sigma}^2\right)$ is converging to σ^2 (i.e. $\hat{\sigma}$ is unbiased) and the variance $\mathrm{V}\left(\hat{\sigma}^2\right)$ is converging to 0 (i.e. $\hat{\sigma}$ is consistent)!

So we finally summarize as following the two important previous results:

1. The "biased maximum likelihood estimator" or also named "empirical standard deviation" or "sample standard deviation" or "Pearson standard deviation" ... is therefore given by:

   $$\boxed{\hat{\sigma}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_i-\hat{\mu})^2}} \tag{5.7.1222}$$

   when $n\rightarrow+\infty$. We find this standard deviation depending on the context (by tradition) noted in five other ways that are:

   $$\sigma^*,S^*,\sigma_*,S_*,S_n \tag{5.7.1223}$$

   and sometimes (but this is very awkward because it often generates confusion with the unbiased estimator) σ or S.

2. The "unbiased maximum likelihood estimator" or simply named "standard deviation" with the "Bessel correction" (the -1 at the denominator is the correction[40]!):

   $$\boxed{\sigma=\sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(x_i-\hat{\mu})^2}} \tag{5.7.1224}$$

   which as we can see is a consistent estimator (when n tends to infinity it tends to the biased maximum likelihood estimator).

   We find this standard deviation depending on the context (by tradition) noted in three other ways that are:

   $$\sigma,S,S_{n-1} \tag{5.7.1225}$$

We find these last two notations often in tables and in many softwares and we will use them later in the development of confidence intervals and hypothesis testing!

For example, in the Microsoft® Excel® 11.8346 the unbiased estimator is given by the `STDEV( )` function and the non-biased by `STDEVP()`.

In total, this makes us is three estimators for the same indicator! As in the overwhelming majority of cases of the industry the mean is not known, we usually use the last two relations bordered above. Now this is where comes the vicious part: when we calculate the bias of this two estimators, the first is biased, the second is not. So we tend to use only the latter. Nay! Because we could also talk about the variance and precision of an estimator, which are also important criteria for judging the quality of an estimator relative to another. If we were to calculate the variance of the two estimators, then the first, which is biased, is smaller than the second which is unbiased variance! All that to say that the criteria of bias is not (by far) the only one to be study to judge the quality of an estimator.

Finally, it is important to remember that the factor -1 in the denominator of the unbiased maximum likelihood estimator stems from the need to correct the mean of the biased estimator initially subtracted by one time the standard error!

---

[40] Some textbooks also define the "Bessel factor" as $n/(n-1)$ like if we multiply the uncorrected sample variance by it we get the unbiased estimator of the population variance.

5.7.7.2 Poisson Distribution MLE

Using the same method as for the Normal (Gauss-Laplace) distribution, we will seek the maximum likelihood estimators of the Poisson distribution which for recall is given by:

$$P_k=\frac{\mu^k}{k!}e^{-\mu} \tag{5.7.1226}$$

Thus, the likelihood is given by:

$$L(\mu)=\prod_{i=1}^{n}P(x_i,\mu)=\frac{\mu^{\sum_{i=1}^{n}x_i}}{\prod_{i=1}^{n}x_i!}e^{-\mu n} \tag{5.7.1227}$$

Maximize a function or maximize its logarithm is equivalent therefore:

$$\ln[L(\mu)]=\ln(\mu)\sum_{i=1}^{n}x_i-\sum_{i=1}^{n}\ln(x_i!)-\mu n \tag{5.7.1228}$$

We are now looking to maximize it:

$$\frac{\partial\ln[L(\mu)]}{\partial\mu}=\frac{1}{\mu}\sum_{i=1}^{n}x_i-n=0 \tag{5.7.1229}$$

and thus we obtain the only maximum likelihood estimator that will be:

$$\boxed{\hat{\mu}=\frac{1}{n}\sum_{i=1}^{n}x_i} \tag{5.7.1230}$$

It is quite normal to find in this example the sample mean because it is the best possible estimator for the parameter of the Poisson distribution (which also represents the mean of a Poisson distribution).

Knowing that the standard deviation of this particular distribution (see above during the development of the Poisson distribution) is the square root of the mean, then we have for the standard deviation maximum likelihood:

$$\boxed{\hat{\sigma}=\sqrt{\frac{1}{\displaystyle\sum_{i=1}^{n}x_i}}} \tag{5.7.1231}$$

Remark

We show in the same way identical results for the exponential distribution that is widely used in preventive maintenance and reliability!

5.7.7.3 Binomial Distribution MLE

Suppose we have a Bernoulli model in which each observation has a constant and equal chance of success denoted p. A Bernoulli variable takes one of two values, conventionally 1 or 0, which indicate a 'success' or 'failure'. The probability distribution for this variable is:

$$\begin{aligned} f(1) &= p \\ f(0) &= 1-p \end{aligned} \tag{5.7.1232}$$

If S stands for the number of successes and F for the number of failures, then the likelihood is:

$$L(p)=\prod_{i=1}^{S} p \prod_{i=1}^{F}(1-p)=p^S(1-p)^F \tag{5.7.1233}$$

and the log-likelihood would then be:

$$\ln(L(p))=S\ln(p)+F\ln(1-p) \tag{5.7.1234}$$

We then take the derivative of this with respect of p:

$$\dfrac{\partial \ln(L(p))}{\partial p}=\dfrac{S}{p}-\dfrac{F}{1-p} \tag{5.7.1235}$$

We now set this equal to zero and solve for p and then we get immediately:

$$\boxed{\hat{p}=\dfrac{S}{S+F}} \tag{5.7.1236}$$

5.7.7.4 Geometric Distribution MLE

Using the same method as for the Normal distribution (Gauss-Laplace) and the Poisson distribution, we will seek the maximum likelihood estimator of the Binomial which we recall, is given by:

$$P(N,k)=C_k^N\cdot P=\dfrac{N!}{k!(N-k!)}p^k q^{N-k}=\dfrac{N!}{k!(N-k!)}p^k(1-p)^{N-k} \tag{5.7.1237}$$

Accordingly, the likelihood is given by:

$$L(p)=\prod_{i=1}^{N}P(x_i,p)=C_k^N p^k(1-p)^{N-k} \tag{5.7.1238}$$

It should be remembered that the factor following the combinatorial term already expressed the successive variables according to what we saw during our study of the Bernoulli and Binomial distribution functions. Hence the disappearance of the product in the preceding equality.

Maximize a function or maximize its logarithm is equivalent therefore:

$$\ln[L(p)]=\ln(C_k^N)+k\ln(p)+(N-k)\ln(1-p) \tag{5.7.1239}$$

We are now looking to maximize it:

$$\frac{\partial \ln[L(p)]}{\partial p}=\frac{k}{p}-\frac{N-k}{1-p}=0 \tag{5.7.1240}$$

The reader may have perhaps noticed that the binomial coefficient has disappeared. Therefore, we immediately deduce that the estimator of the binomial distribution is the same as the geometric distribution.

Which gives:

$$k(1-p)-p(N-k)=k-kp-pN+pk=k-pN=0 \tag{5.7.1241}$$

from which we derive the maximum likelihood estimator:

$$\boxed{\hat{p}=\frac{k}{N}} \tag{5.7.1242}$$

This result is quite intuitive if we consider the classic example of a coin that has a chance on two of dropping on one of its faces. The probability p being the number of times k a given face where was observed in the total number of tests (all sides combined).

Remark

In practice, it is not as easy to apply these estimators! We must carefully consider which are most suitable for a given experiment and ideally also calculate the mean squared error (standard error) of each of the estimators of the mean (as we have already done for the empirical mean earlier). In short... it is a long process of reflection.

5.7.7.5 Weibull Distribution MLE

We saw in the section of Industrial Engineering a very detailed study of the three-parameter Weibull distribution with its standard deviation and mean because as we mentioned it is quite used in the field of reliability engineering (see section Industrial Engineering page 8736).

Unfortunately, the three parameters of this distribution are unknown in practice. Using estimators however we can determine the expression of two of the three assuming γ as zero. This gives us the following Weibull distribution named "Weibull distribution with two parameters":

$$P(x,\beta,\eta)=\frac{\beta}{\eta}\left(\frac{x}{\eta}\right)^{\beta-1}e^{-\left(\frac{x}{n}\right)^{\beta}} \tag{5.7.1243}$$

and for recall with $\beta>0$ and $\eta>0$.

Therefore the likelihood is given by:

$$L(\beta,\eta)=\prod_{i=1}^{n}P(x_i,\beta,\eta)=\prod_{i=1}^{n}\frac{\beta}{\eta}\left(\frac{x_i}{\eta}\right)^{\beta-1}e^{-\left(\frac{x_i}{n}\right)^{\beta}}=\left(\frac{\beta}{\eta}\right)^{n}\prod_{i=1}^{n}\left(\frac{x_i}{\eta}\right)^{\beta-1}e^{-\sum_{i=1}^{n}\left(\frac{x_i}{n}\right)^{\beta}} \tag{5.7.1244}$$

Maximize a function or maximize its logarithm is equivalent therefore:

$$\begin{aligned}\ln(L(\beta,\eta)) &= \ln\left(\left(\frac{\beta}{\eta}\right)^n\prod_{i=1}^n\left(\frac{x_i}{\eta}\right)^{\beta-1}e^{\sum_{i=1}^n\left(\frac{x_i}{\eta}\right)^\beta}\right)\\ &= n\ln\left(\frac{\beta}{\eta}\right)-\frac{1}{\eta^\beta}\sum_{i=1}^n x_i^\beta+\sum_{i=1}^n\ln\left[\left(\frac{x_i}{\eta}\right)^{\beta-1}\right]\\ &= n\ln\left(\frac{\beta}{\eta}\right)-\eta^{-\beta}\sum_{i=1}^n x_i^\beta+(\beta-1)\sum_{i=1}^n\ln\left(\frac{x_i}{\eta}\right)\end{aligned}\tag{5.7.1245}$$

Now we seek to maximize this by remembering that (see section Differential and Integral Calculus page 1475):

$$\frac{\mathrm{d}}{\mathrm{d}x}a^x=a^x\ln(a)\quad\text{and}\quad\frac{\mathrm{d}}{\mathrm{d}x}a^{-x}=-a^x\ln(a)\tag{5.7.1246}$$

then:

$$\begin{aligned}\frac{\partial\ln(\beta,\eta)}{\partial\beta} &= n\frac{1}{\beta}+\frac{1}{\eta^\beta}\ln(\eta)\sum_{i=1}^n x_i^\beta-\frac{1}{\eta^\beta}\sum_{i=1}^n x_i^\beta\ln(x_i)+\sum_{i=1}^n\ln\left(\frac{x_i}{\eta}\right)\\ &= n\frac{1}{\beta}+\frac{1}{\eta^\beta}\left[\sum_{i=1}^n x_i^\beta\left(\ln(\eta)-\ln(x_i)\right)\right]+\sum_{i=1}^n\ln\left(\frac{x_i}{\eta}\right)\\ &= n\frac{1}{\beta}-\frac{1}{\eta^\beta}\left[\sum_{i=1}^n x_i^\beta\left(\ln(x_i)-\ln(\eta)\right)\right]+\sum_{i=1}^n\ln\left(\frac{x_i}{\eta}\right)\\ &= n\frac{1}{\beta}-\frac{1}{\eta^\beta}\sum_{i=1}^n x_i^\beta\ln\left(\frac{x_i}{\eta}\right)+\sum_{i=1}^n\ln\left(\frac{x_i}{\eta}\right)=0\end{aligned}\tag{5.7.1247}$$

And we get for the second parameter:

$$\frac{\partial\ln(\beta,\eta)}{\partial\eta}=-n\frac{1}{\nu}-\frac{\beta}{\eta^\beta\eta}\sum_{i=1}^n x_i^\beta+(1-\beta)n\frac{1}{\eta}=0\tag{5.7.1248}$$

then:

$$-\frac{1}{\eta^\beta}\sum_{i=1}^n x_i^\beta-n=0\tag{5.7.1249}$$

Finally to summarize with the correct notations (and in the resolution order in practice):

$$n\frac{1}{\hat{\beta}}-\frac{1}{\hat{\eta}^{\hat{\beta}}}\sum_{i=1}^n x_i^{\hat{\beta}}\ln\left(\frac{x_i}{\eta}\right)+\sum_{i=1}^n\ln\left(\frac{x_i}{\eta}\right)=0\quad\text{and}\quad-\frac{1}{\hat{\eta}^{\hat{\beta}}}\sum_{i=1}^n x_i^{\hat{\beta}}-n=0\tag{5.7.1250}$$

Solving these equations involves heavy computations and we can a priori do nothing with that in conventional spreadsheets softwares such as Microsoft® Excel® or Open Office Calc without programming (at least as far as we know...).

We then take a different approach by writing our Weibull distribution with two parameters as follows:

$$P(x,\beta,\theta)=\frac{\beta}{\theta}x^{\beta-1}e^{\frac{x^\beta}{\theta}} \tag{5.7.1251}$$

with for recall $\beta>0$ and $\theta>0$.

Therefore the likelihood is given by:

$$L(\beta,\eta)=\prod_{i=1}^{n}P(x_i,\beta,\theta)=\prod_{i=1}^{n}\frac{\beta}{\theta}x_i^{\beta-1}e^{-\frac{x_i^\beta}{\theta}}=\left(\frac{\beta}{\theta}\right)^n e^{-\sum\limits_{i=1}^{n}\dfrac{x_i^\beta}{\theta}}\prod_{i=1}^{n}x_i^{\beta-1} \tag{5.7.1252}$$

Maximize a function or maximize its logarithm is equivalent therefore:

$$\begin{aligned}\ln(L(\beta,\eta))&=\ln\left[\left(\frac{\beta}{\theta}\right)^n e^{-\sum\limits_{i=1}^{n}\dfrac{x_i^\beta}{\theta}}\prod_{i=1}^{n}x_i^{\beta-1}\right]\\&=n\ln\frac{\beta}{\theta}-\frac{1}{\theta}\sum_{i=1}^{n}x_i^\beta+\sum_{i=1}^{n}\ln(x_i^{\beta-1})=n\ln\frac{\beta}{\theta}-\frac{1}{\theta}\sum_{i=1}^{n}x_i^\beta+(\beta-1)\sum_{i=1}^{n}\ln(x_i)\end{aligned} \tag{5.7.1253}$$

Now we seek to maximize this by remembering that (see section Differential and Integral Calculus page 1475):

$$\frac{\mathrm{d}}{\mathrm{d}x}a^x=a^x\ln(a)\quad\text{and}\quad\frac{\mathrm{d}}{\mathrm{d}x}a^{-x}=-a^x\ln(a) \tag{5.7.1254}$$

then:

$$\frac{\partial\ln(\beta,\theta)}{\partial\beta}=\frac{n}{\beta}-\frac{1}{\theta}\sum_{i=1}^{n}x_i^\beta\ln(x_i)+\sum_{i=1}^{n}\ln(x_i)=0 \tag{5.7.1255}$$

And we have for the second parameter:

$$\frac{\partial\ln(\beta,\theta)}{\partial\theta}=-\frac{n}{\theta}+\frac{1}{\theta^2}\sum_{i=1}^{n}x_i^\beta=0 \tag{5.7.1256}$$

It is then immediate that:

$$\bar{\theta}=\frac{1}{n}\sum_{i=1}^{n}x_i^\beta \tag{5.7.1257}$$

injected into the equation:

$$\frac{n}{\beta}-\frac{1}{\theta}\sum_{i=1}^{n}x_i^\beta\ln(x_i)+\sum_{i=1}^{n}\ln(x_i)=0 \tag{5.7.1258}$$

We get:

$$\frac{n}{\beta}-\frac{\displaystyle\sum_{i=1}^{n}x_i^{\beta}\ln(x_i)}{\displaystyle\frac{1}{n}\sum_{i=1}^{n}x_i^{\beta}}+\sum_{i=1}^{n}\ln(x_i)=0 \tag{5.7.1259}$$

simplifying:

$$\frac{\displaystyle\sum_{i=1}^{n}x_i^{\beta}\ln(x_i)}{\displaystyle\frac{1}{n}\sum_{i=1}^{n}x_i^{\beta}}-\frac{1}{\beta}=\frac{1}{n}\sum_{i=1}^{n}\ln(x_i) \tag{5.7.1260}$$

The resolution of the two equations (in order from top to bottom):

$$\boxed{\begin{aligned}&\frac{\displaystyle\sum_{i=1}^{n}x_i^{\beta}\ln(x_i)}{\displaystyle\frac{1}{n}\sum_{i=1}^{n}x_i^{\beta}}-\frac{1}{\beta}-\frac{1}{n}\sum_{i=1}^{n}\ln(x_i)=0\\&\frac{1}{n}\sum_{i=1}^{n}x_i^{\beta}-\bar{\theta}\end{aligned}} \tag{5.7.1261}$$

can easily be calculated with the Target Tool of Microsoft® Excel® or Open Office Calc.

5.7.7.6 Gamma Distribution MLE

Here we will use a technique named "method of moments" to determine the estimators of the parameters of the Gamma distribution.

Suppose that $X_1,\ldots,X_n$ are independent and identically distributed random variables according to the Gamma distribution with density:

$$P_{a,\lambda}(x)=\frac{x^{a-1}e^{-\lambda x}}{\Gamma(a)}\lambda^{a}1_{[0,+\infty[} \tag{5.7.1262}$$

We seek to estimate a,λ. For this, we first determine some theoretical moments. The first moment is the expected mean that as we have proved before is given by:

$$\mathrm{E}(X)=m_1=\frac{a}{\lambda} \tag{5.7.1263}$$

and the second moment, the mean of the square of the random variable, is as we have implicitly proved in the proof of the variance of the Gamma distribution given by:

$$\mathrm{E}(X^2)=m_2=\frac{a(a+1)}{\lambda^2} \tag{5.7.1264}$$

We then express the relation between the parameters and the theoretical moments:

$$\begin{aligned} m_1 &= \frac{a}{\lambda} \\ m_2 &= \frac{a(a+1)}{\lambda^2} \end{aligned} \tag{5.7.1265}$$

The resolution of this simple system gives:

$$\begin{aligned} a &= \frac{m_1^2}{m_2 - m_1^2} \\ \lambda &= \frac{m_2 - m_1^2}{m_1^2} \end{aligned} \tag{5.7.1266}$$

Once this system established, the method of moments consist to use the empirical moments, i.e. for our example the first two, $\hat{m}_1, \hat{m}_2$:

$$\begin{aligned} \hat{m}_1 &= \frac{X_1 + \ldots + X_n}{n} \\ \hat{m}_2 &= \frac{X_1^2 + \ldots + X_n^2}{n} \end{aligned} \tag{5.7.1267}$$

that we define as equal to the true theoretical moments ... Therefore, it comes:

$$\boxed{\begin{aligned} a &= \frac{\hat{m}_1^2}{\hat{m}_2 - \hat{m}_1^2} \\ \lambda &= \frac{\hat{m}_2 - \hat{m}_1^2}{\hat{m}_1^2} \end{aligned}} \tag{5.7.1268}$$

5.7.7.7 Pareto Distribution MLE

Let us recall the Pareto density given by:

$$f(x) = k\frac{x_m^k}{x^{k+1}} \tag{5.7.1269}$$

Let us choose a more convenient and traditional notation:

$$f(x, \alpha, \beta) = \alpha\frac{\beta^\alpha}{x^\alpha} \qquad x \geq \beta \qquad \alpha, \beta > 0 \tag{5.7.1270}$$

The likelihood function of the Pareto distribution given a sample $x = (x_1, \ldots, x_n)$ is given by:

$$L(\alpha, \beta, x) = \prod_{i=1}^{n} \alpha\frac{\beta^\alpha}{x_i^{\alpha+1}} = \alpha^n \beta^{n\alpha} \prod_{i=1}^{n} \frac{1}{x_i^{\alpha+1}} \tag{5.7.1271}$$

Taking the log of the likelihood, we obtain:

$$\ln[L(\alpha, \beta; x)] \equiv \ell(\alpha, \beta; x) = n\ln(\alpha) + n\alpha\ln(\beta) - (\alpha+1)\sum_{i=1}^{n} \ln(x_i). \tag{5.7.1272}$$

Since a higher β will always result in a higher likelihood - $\ln(\beta)$ is monotonically increasing - we maximize the likelihood by setting $\hat{\beta}$ as high as possible (we can't use differentiation to maximize the likelihood in this case). Since $\beta \leq x_i$ for all i, we maximize the likelihood by setting $\hat{\beta} = \min\limits_i x_i$, the smallest x_i in the sample.

For α, we set the partial derivative of ℓ with respect to α equal to 0:

$$\frac{\partial \ell(\alpha,\beta)}{\partial \alpha} = \frac{n}{\alpha} + n\ln(\beta) - \sum_{i=1}^{n} \ln\left(x_i\right) = 0 \qquad (5.7.1273)$$

Therefore:

$$\hat{\alpha} = \frac{n}{\displaystyle\sum_{i=1}^{n} \ln\left(x_i\right) - n\ln(\hat{\beta})} = \frac{1}{\displaystyle\frac{1}{n}\sum_{i=1}^{n} \ln\left(x_i\right) - n\ln(\hat{\beta})} \qquad (5.7.1274)$$

5.7.7.8 Censored data MLE

The "likelihood of censored data" is of crucial importance in the field of industrial reliability and also in pharmacies and clinical studies, knowing that for reasons of cost and unforeseen circumstances, there is often a limit to the time of observation or events which make that the subjects of study leave the experiment. Knowing that there are four types of situations (see figure below if needed):

1. "Uncensored data" (un), the event of interest is observed between the start time of measurement and end of measurement.
2. "Right-censored" (rc), the event did not occur during the limited observation time, that is, between the measurement start and end time.
3. "Left-censored" (lc), the object of study left the experiment for whatever reasons observed between the time of beginning of measurement and end of measurement, or we do not know with precision at which what should have been measured started.
4. "Censorship interval" (ci), an event of interest took place between two instants, but we do not know exactly when in this interval (before, between or after the measurement periods).

Figure 5.157: **Type of censored data**

It is then relatively intuitive that if all events are independent then the likelihood function will be given by:

$$L(\theta)=\prod_{T_i\in\text{uc}}P(T=T_i,\theta)\prod_{T_i\in\text{lc}}P(T<T_i,\theta)\prod_{T_i\in\text{rc}}P(T>T_i,\theta)\prod_{T_i\in\text{ci}}P(T_{i,l}<T<T_{i,r},\theta) \tag{5.7.1275}$$

where the index l is for "left" and the index r is for "right".

We have obviously (think of the discrete case before thinking of the continuous case):

$$\begin{aligned}P(T=T_i,\theta)&=f(T_i,\theta)\\P(T<T_i,\theta)&=F(T_i,\theta)=1-R(T_i,\theta)\\P(T>T_i,\theta)&=1-F(T_i,\theta)=R(T_i,\theta)\\P(T_{i,l}<T<T_{i,r},\theta)&=F(T_{t,r},\theta)-F(T_{t,l},\theta)=R(T_{i,l},\theta)-R(T_{i,r},\theta)\end{aligned} \tag{5.7.1276}$$

In the field of reliability engineering that interest us here, we often reduce ourselves to the following cases:

$$L(\theta)=\prod_{T_i\in\text{uc}}P(T=T_i,\theta)\prod_{T_i\in\text{rc}}P(T>T_i,\theta) \tag{5.7.1277}$$

but with the following notation (...):

$$\boxed{L(\theta)=\prod_{T_i\in\text{uc}}P(T=T_i,\theta)\prod_{T_i\in\text{rc}}R(T_i,\theta)} \tag{5.7.1278}$$

In many experiments, the number of faulty elements f to be observed on n is fixed in advance (we often speak of "type II censorship") or simply known afterwards. Therefore, we have:

$$L(\theta)=\prod_{i=1}^{f} P(T=T_i,\theta)\prod_{i=f+1}^{n} R(T_i,\theta) \tag{5.7.1279}$$

Let us explicit this probability with Weibull's law. Let us recall that a possible form of writing of the density function is written for the latter (see section Industrial Engineering page 8736):

$$f(x)=\frac{\alpha}{\beta}\frac{x^{\alpha-1}}{\beta^{\alpha-1}}e^{-\frac{x^{\alpha}}{\beta^{\alpha}}}=\frac{\alpha}{\beta}x^{\alpha-1}e^{-\left(\frac{x}{\beta}^{\alpha}\right)} \tag{5.7.1280}$$

and that we have proved that its survival function was given by:

$$R(x)=e^{-\left(\frac{x}{\beta}^{\alpha}\right)} \tag{5.7.1281}$$

Therefore:

$$L(\alpha,\beta)=\prod_{i=1}^{f}\frac{\alpha}{\beta}\left(\frac{t_i}{\beta}\right)^{\alpha-1}e^{-\left(\frac{t_i}{\beta}\right)^{\alpha}}\prod_{i=f+1}^{n}e^{-\left(\frac{t_i}{\beta}\right)^{\alpha}}=\left(\frac{\alpha}{\beta^{\alpha}}\right)^{f}e^{-\frac{1}{\beta^{\alpha}}\sum_{i=1}^{n}t_i^{\alpha}}\prod_{i=1}^{f}t_i^{\alpha-1} \tag{5.7.1282}$$

Maximizing the likelihood is equivalent to maximizing the logarithm. Since then:

$$\ln[L(\alpha,\beta)]=f\ln(\alpha)-f\alpha\ln(\beta)-\sum_{i=1}^{n}\left(\frac{t_i}{\beta}\right)^{\alpha}+(\alpha-1)\sum_{i=1}^{f}\ln(t_i) \tag{5.7.1283}$$

We calculate the partial derivative with respect to α, β (see section of Differential and Integral Calculus page 1475):

$$\begin{aligned}\frac{\partial\ln[L(\alpha,\beta)]}{\partial\alpha}&=\frac{f}{\alpha}-f\ln(\beta)-\sum_{i=1}^{n}\left(\frac{t_i}{\beta}\right)^{\alpha}\ln\left(\frac{t_i}{\beta}\right)+\sum_{i=1}^{f}\ln(t_i)=0\\ \frac{\partial\ln[L(\alpha,\beta)]}{\partial\alpha}&=-\frac{f\alpha}{\beta}+\frac{\alpha}{\beta}\sum_{i=1}^{n}\left(\frac{t_i}{\beta}\right)^{\alpha}=0\end{aligned} \tag{5.7.1284}$$

The second relation can easily be explicited with respect to β such that:

$$\hat{\beta}=\left(\frac{1}{f}\sum_{i=1}^{n}t_i^{\alpha}\right)^{1/\hat{\alpha}} \tag{5.7.1285}$$

In any case, it seems that it will be necessary to use numerical optimization techniques to determine all parameters.

5.7.7.9 Fisher Information Matrix

We will introduce now a matrix that will be useful to us much more later for some advanced statistical tests but also to determine (among others!) non-obvious statistical law parameters and also an important information criterion named the "Akaike Information Criterion" (see section Numerical Methods page 6420).

We have seen earlier that the partial derivative of the log-likelihood (that we will denote $\mathcal{L}$ for the following developments) relatively to a given parameter θ_i of a probability function (depending of a set of parameters $\vec{\theta}$) will give us an estimator of this parameter if put it as equal to zero.

Also respectively we then have that the partial derivative valuated at this correspond estimator then gives:

$$\frac{\partial\mathcal{L}(\vec{\theta})}{\partial\theta_i}(\hat{\theta})=0 \tag{5.7.1286}$$

Remark

The expression:

$$\mathcal{S}_i(\vec{\theta})=\frac{\partial\mathcal{L}(\vec{\theta})}{\partial\theta_i}(\hat{\theta})=\frac{\partial\ln(L(\vec{\theta}))}{\partial\theta_i}(\hat{\theta}) \tag{5.7.1287}$$

is known as the "score function".

Let us recall that during our study of bivariate Taylor series (see section Sequences and Series page 1714), we have proved that:

$$f(x_0+h,y_0+k)\cong f(x_0,y_0)+\frac{\partial f}{\partial x}(x_0,y_0)h+\frac{\partial f}{\partial y}(x_0,y_0)k+\frac{1}{2!}(h\ k)H\begin{pmatrix}h\\k\end{pmatrix} \tag{5.7.1288}$$

where:

$$H=\begin{bmatrix}\dfrac{\partial^2 f}{\partial x^2} & \dfrac{\partial^2 f}{\partial x\partial y}\\ \dfrac{\partial^2 f}{\partial y\partial x} & \dfrac{\partial^2 f}{\partial y^2}\end{bmatrix} \tag{5.7.1289}$$

Let us do the following replacement:

$$h=x-x_0\qquad k=y-y_0 \tag{5.7.1290}$$

We then have:

$$f(x,y)\cong f(x_0,y_0)+\frac{\partial f}{\partial x}(x_0,y_0)(x-x_0)+\frac{\partial f}{\partial y}(x_0,y_0)(y-y_0)+\frac{1}{2!}(x-x_0\ y-y_0)H\begin{pmatrix}x-x_0\\y-y_0\end{pmatrix} \tag{5.7.1291}$$

Remark

In the univariate case this is also written:

$$f(x) \cong f(x_0) + \frac{\partial f}{\partial x}(x_0)(x-x_0) + \frac{1}{2!}(x-x_0)H(x-x_0) \tag{5.7.1292}$$

or in some textbooks:

$$f(x) \cong f(x_0) + \frac{\partial f}{\partial x}(x_0)(x-x_0) + \frac{1}{2!}(x-x_0)H(x_0)(x-x_0) \tag{5.7.1293}$$

In vector form this is often written:

$$f(\vec{v}) \cong f(\vec{v}_0) + \left(\vec{\nabla} f(\vec{v}_0)\right) \circ (\vec{v}) + \frac{1}{2!}\vec{v}^T H \vec{v} \tag{5.7.1294}$$

Now remember that $f(\vec{v}_0)$ and $\vec{\nabla} f(\vec{v}_0)$ does not contain anymore any term in x or y as the function is 'valuated'. Hence if we take the gradient of the whole previous expression, we get:

$$\vec{\nabla} f(\vec{v}) \cong \underbrace{\vec{\nabla} f(\vec{v}_0)}_{=0} + \vec{\nabla}\left(\vec{\nabla} f(\vec{v}_0) \circ (\vec{v})\right) + \frac{1}{2!}\vec{\nabla}\left(\vec{v}^T H \vec{v}\right) = \vec{\nabla} f(\vec{v}_0) + H\vec{v} \tag{5.7.1295}$$

If you don't understand that result, do it again with the univariate case may help. Indeed, starting from:

$$f(x) \cong f(x_0) + \frac{\partial f}{\partial x}(x_0)(x-x_0) + \frac{1}{2!}(x-x_0)H(x_0)(x-x_0) \tag{5.7.1296}$$

We then have in a very very detailed way:

$$\begin{aligned}
\frac{\partial f(x)}{\partial x} &\cong \underbrace{\frac{\partial f(x_0)}{\partial x}}_{=0} + \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}(x_0)(x-x_0)\right) + \frac{1}{2!}\frac{\partial}{\partial x}\left((x-x_0)H(x_0)(x-x_0)\right)\\
&= \underbrace{\frac{\partial^2 f}{\partial x^2}(x_0)(x-x_0)}_{=0} + \frac{\partial f}{\partial x}(x_0)\underbrace{\frac{\partial f}{\partial x}(x-x_0)}_{=1}\\
&+ \frac{1}{2!}\left(\underbrace{\frac{\partial f}{\partial x}(x-x_0)}_{=1}H(x_0)(x-x_0) + \underbrace{(x-x_0)\frac{\partial f}{\partial x}H(x_0)(x-x_0)}_{=0} + (x-x_0)H(x_0)\underbrace{\frac{\partial f}{\partial x}(x-x_0)}_{=1}\right)\\
&= \frac{\partial f}{\partial x}(x_0) + \frac{1}{2!}\left(H(x_0)(x-x_0) + (x-x_0)H(x_0)\right) = \frac{\partial f}{\partial x}(x_0) + \frac{1}{2!}\left(2H(x_0)(x-x_0)\right)\\
&= \frac{\partial f}{\partial x}(x_0) + H(x_0)(x-x_0)
\end{aligned} \tag{5.7.1297}$$

That latter equality can indeed be written:

$$\vec{\nabla} f(x) \cong \vec{\nabla} f(x_0) + H(x_0)(x-x_0) \tag{5.7.1298}$$

Now let us come back to the more general equality:

$$\boxed{\vec{\nabla} f(\vec{v}) \cong \vec{\nabla} f(\vec{v}_0) + H\vec{v}} \tag{5.7.1299}$$

We can solve this expression for the optimal point $\vec{\nabla} f(\vec{v}) = \vec{0}$, giving:

$$\vec{0} \cong \vec{\nabla} f(\vec{v}_0) + H\vec{v} = \vec{\nabla} f \begin{pmatrix} x - x_0 \\ y - y_0 \end{pmatrix} + H \begin{pmatrix} x - x_0 \\ y - y_0 \end{pmatrix} \tag{5.7.1300}$$

Hence:

$$\boxed{\begin{pmatrix} x \\ y \end{pmatrix} \cong \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} - H^{-1}\vec{\nabla} f \begin{pmatrix} x - x_0 \\ y - y_0 \end{pmatrix}} \tag{5.7.1301}$$

This is the Newton-Raphson method for multidimensional optimization by the way...

Now let us focus on the following equality from the previous one:

$$\begin{pmatrix} x - x_0 \\ y - y_0 \end{pmatrix} \cong -H^{-1}\vec{\nabla} f \begin{pmatrix} x - x_0 \\ y - y_0 \end{pmatrix} \tag{5.7.1302}$$

And let us change the notation and replace f by $\mathcal{L}$:

$$\begin{pmatrix} \theta_1 - \theta_{1,0} \\ \theta_2 - \theta_{2,0} \end{pmatrix} \cong -H^{-1}\vec{\nabla}\mathcal{L} \begin{pmatrix} \theta_1 - \theta_{1,0} \\ \theta_2 - \theta_{2,0} \end{pmatrix} = H^{-1}\vec{\nabla}\mathcal{L}(\vec{\theta}) \tag{5.7.1303}$$

where $\vec{\nabla}\mathcal{L}(\vec{\theta})$ (the gradient of the likelihood at the point $\vec{\theta}$) is named the "score vector".

Remark

In the univariate case this is will also be reduced to:

$$\theta - \theta_0 \cong -H^{-1}\frac{\partial \mathcal{L}(\theta_0)}{\partial \theta} = -\left[\frac{\partial^2 \mathcal{L}(\theta_0)}{\partial \theta^2}\right]^{-1} \frac{\partial \mathcal{L}(\theta_0)}{\partial \theta} \tag{5.7.1304}$$

Now let us have a bit 'fun'... Let us take the outer product (see section Linear Algebra page 2014) of $\vec{\theta}$, i.e.:

$$\vec{\theta}\vec{\theta}^T = \begin{pmatrix} \theta_1 - \theta_{1,0} \\ \theta_2 - \theta_{2,0} \end{pmatrix} \begin{pmatrix} \theta_1 - \theta_{1,0} & \theta_2 - \theta_{2,0} \end{pmatrix} = \begin{bmatrix} (\theta_1 - \theta_{1,0})^2 & (\theta_1 - \theta_{1,0})(\theta_2 - \theta_{2,0}) \\ \theta_2 - \theta_{2,0} & (\theta_2 - \theta_{2,0})^2 \end{bmatrix} \tag{5.7.1305}$$

Ok so far nothing interesting. But let us take the expected mean:

$$\mathrm{E}(\vec{\theta}\vec{\theta}^T) = \begin{bmatrix} \mathrm{E}(\theta_1 - \theta_{1,0})^2 & \mathrm{E}((\theta_1 - \theta_{1,0})(\theta_2 - \theta_{2,0})) \\ \mathrm{E}((\theta_2 - \theta_{2,0})(\theta_1 - \theta_{1,0})) & \mathrm{E}(\theta_2 - \theta_{2,0})^2 \end{bmatrix} \tag{5.7.1306}$$

Here we recognize something! The elements of the diagonal look similar to a variance... The variance of θ_1 relatively to $\theta_{1,0}$. It is common to assume that θ_1 is the estimator and $\theta_{1,0}$ is the true value, then we write (keep in mind that this can be generalized to more than 2 parameters!):

$$\mathrm{E}(\vec{\theta}\vec{\theta}^T) = \begin{bmatrix} \mathrm{E}(\hat{\theta}_1 - \theta_1)^2 & \mathrm{E}((\hat{\theta}_1 - \theta_1)(\hat{\theta}_2 - \theta_2)) \\ \mathrm{E}((\hat{\theta}_2 - \theta_2)(\hat{\theta}_1 - \theta_1)) & \mathrm{E}(\hat{\theta}_2 - \theta_2)^2 \end{bmatrix} = \begin{bmatrix} \mathrm{V}(\hat{\theta}_1) & \mathrm{cov}(\hat{\theta}_1, \hat{\theta}_2) \\ \mathrm{cov}(\hat{\theta}_1, \hat{\theta}_2) & \mathrm{V}(\hat{\theta}_2 - \theta_2)) \end{bmatrix} = \Sigma(\vec{\theta}) \tag{5.7.1307}$$

We recognize here the variance-covariance matrix[41] (see above page 604). Ok that's nice but so what??? What does this bring us? In fact using previous equalities we have:

$$\mathrm{E}(\vec{\theta}\vec{\theta}^T) = \Sigma(\vec{\theta}) \cong \mathrm{E}\left[\left(H^{-1}\vec{\nabla}\mathcal{L}(\vec{\theta})\right)\left(H^{-1}\vec{\nabla}\mathcal{L}(\vec{\theta})\right)^T\right] \tag{5.7.1308}$$

---

[41] Sadly denoted in some textbooks $\mathrm{V}(\vec{\theta})$...

Using the properties of transposition as proved in the section of Linear Algebra and the property of matrix multiplication association property, that latter relation can be written:

$$\Sigma(\vec{\theta}) \cong \mathrm{E}\left[\left(H^{-1}\vec{\nabla}\mathcal{L}(\vec{\theta})\right)\left(\vec{\nabla}\mathcal{L}(\vec{\theta})^T(H^{-1})^T\right)\right] = \mathrm{E}\left[H^{-1}\left(\vec{\nabla}\mathcal{L}(\vec{\theta})\vec{\nabla}\mathcal{L}(\vec{\theta})^T\right)(H^{-1})^T\right] \tag{5.7.1309}$$

Using another property of the transposed, this can be also written:

$$\Sigma(\vec{\theta}) \cong \mathrm{E}\left[H^{-1}\left(\vec{\nabla}\mathcal{L}(\vec{\theta})\vec{\nabla}\mathcal{L}(\vec{\theta})^T\right)(H^T)^{-1}\right] \tag{5.7.1310}$$

Assuming the Hessian is symmetric such that $H^T = H$ (if Schwarz's theorem[42] applies on the function considered inside the Hessian!), we then have:

$$\Sigma(\vec{\theta}) \cong \mathrm{E}\left[H^{-1}\left(\vec{\nabla}\mathcal{L}(\vec{\theta})\vec{\nabla}\mathcal{L}(\vec{\theta})^T\right)H^{-1}\right] \tag{5.7.1311}$$

Using the linearity property of the mean:

$$\Sigma(\vec{\theta}) \cong \left[\mathrm{E}(H^{-1})\mathrm{E}\left(\vec{\nabla}\mathcal{L}(\vec{\theta})\vec{\nabla}\mathcal{L}(\vec{\theta})^T\right)\mathrm{E}(H^{-1})\right] \tag{5.7.1312}$$

Now let us focus on:

$$\mathrm{E}\left(\vec{\nabla}\mathcal{L}(\vec{\theta})\vec{\nabla}\mathcal{L}(\vec{\theta})^T\right) \tag{5.7.1313}$$

But we need an important result before! As the likelihood $L(\vec{x}),\vec{\theta})$ is a density, we know that:

$$\int L(\vec{x},\vec{\theta})\mathrm{d}x = 1 \tag{5.7.1314}$$

Now by differentiating both sides with respect to one of the parameter θ_i we get:

$$\frac{\partial}{\partial\theta_i}\int L(\vec{x},\vec{\theta})\mathrm{d}x = 0 \tag{5.7.1315}$$

By assuming (this assumption must be checked on every case!) that we have:

$$\frac{\partial}{\partial\theta_i}\int L(\vec{x},\vec{\theta})\mathrm{d}x = \int\frac{\partial L(\vec{x},\vec{\theta})}{\partial\theta_i}\mathrm{d}x \tag{5.7.1316}$$

Then:

$$\int\frac{\partial L(\vec{x},\vec{\theta})}{\partial\theta_i}\mathrm{d}x = 0 \tag{5.7.1317}$$

But this is also equal to:

$$\int\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}L(\vec{x},\vec{\theta})\mathrm{d}x = 0 \tag{5.7.1318}$$

---

[42] See section Differential and Integral Calculus page 1469

Differentiating again with respect to θ_i and taking the derivative inside gives:

$$\begin{aligned}\frac{\partial}{\partial\theta_i}\int\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}L(\vec{x},\vec{\theta})\mathrm{d}x&=\int\frac{\partial^2\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i^2}L(\vec{x},\vec{\theta})\mathrm{d}x+\int\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}\frac{\partial L(\vec{x},\vec{\theta})}{\partial\theta_i}\mathrm{d}x\\&=\int\frac{\partial^2\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i^2}L(\vec{x},\vec{\theta})\mathrm{d}x+\int\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}\frac{1}{L(\vec{x},\vec{\theta})}\frac{\partial L(\vec{x},\vec{\theta})}{\partial\theta_i}L(\vec{x},\vec{\theta})\mathrm{d}x\\&=\int\frac{\partial^2\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i^2}L(\vec{x},\vec{\theta})\mathrm{d}x+\int\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}L(\vec{x},\vec{\theta})\mathrm{d}x\\&=0\end{aligned}\tag{5.7.1319}$$

Hence:

$$\int\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}L(\vec{x},\vec{\theta})\mathrm{d}x=-\int\frac{\partial^2\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i^2}L(\vec{x},\vec{\theta})\mathrm{d}x\tag{5.7.1320}$$

Written in a more common way by statisticians as following:

$$\mathrm{E}\left(\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}\frac{\partial\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i}\right)=-\mathrm{E}\left(\frac{\partial^2\ln(L(\vec{x},\vec{\theta}))}{\partial\theta_i^2}\right)\tag{5.7.1321}$$

And using the notation defined earlier:

$$\mathrm{E}\left(\frac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i}\frac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i}\right)=-\mathrm{E}\left(\frac{\partial^2\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i^2}\right)\tag{5.7.1322}$$

If we do the same development again but when taking the partial derivative a second time but relatively to θ_j instead of θ_i we get immediately:

$$\mathrm{E}\left(\frac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i}\frac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_j}\right)=-\mathrm{E}\left(\frac{\partial^2\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i\partial\theta_j}\right)=-\mathrm{E}\left(\frac{\partial^2\mathcal{L}(\vec{x},\vec{\theta})}{\partial\vec{\theta}}\right)\tag{5.7.1323}$$

This can be put obviously in matrix form for each component i,j. Then it is usual to define the mean of matrix made of the components $\frac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i}\frac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_j}$ as the "Fisher information matrix" denoted $\mathcal{I}(\vec{\theta})$ and we recognize that a matrix made of the components $\frac{\partial^2\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_i\partial\theta_j}$ is the "Hessian" (see section Sequences and Series page 1715) denoted for recall $H(\vec{\theta})$, then we have:

$$\boxed{\mathcal{I}(\vec{\theta})=-\mathrm{E}\left(H(\vec{\theta})\right)}\tag{5.7.1324}$$

And this is the relation we were expecting to find!

So now let us come back to:

$$\Sigma(\vec{\theta})=\left[\mathrm{E}(H^{-1})\mathrm{E}\left(\vec{\nabla}\mathcal{L}(\vec{\theta})\vec{\nabla}\mathcal{L}(\vec{\theta})^T\right)\mathrm{E}(H^{-1})\right]\tag{5.7.1325}$$

That we can now rewrite as:

$$\Sigma(\vec{\theta})=\left[\mathrm{E}(H^{-1})\mathcal{I}(\vec{\theta})\mathrm{E}(H^{-1})\right]=\left[\mathrm{E}(H^{-1})(-\mathrm{E}(H(\vec{\theta}))\mathrm{E}(H^{-1})\right]=-\left[\mathrm{E}(H^{-1})\mathrm{E}(H)\mathrm{E}(H^{-1})\right]\tag{5.7.1326}$$

So finally we get the important final result we were seeking from the start named the "information matrix equality":

$$\boxed{\Sigma(\vec{\theta}) \cong -\mathrm{E}(H^{-1})} \tag{5.7.1327}$$

That is that the covariance-variance matrix (itself equal to the outer product of $\vec{\theta}$ with itself!), is equal to the negative on the inverse Hessian! Or in other words: the hessian of a likelihood function equals the information matrix, or the variance-covariance matrix of the score functions!

✍**Example:**

Our sample is made up of the first n terms of an independent and identically distributed sequence $\{X_n\}$ of normal random variables having mean μ and variance σ^2. The probability density function of a generic term of the sequence is:

$$f_X(x_j) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2}\frac{(x_j-\mu)^2}{\sigma^2}} \tag{5.7.1328}$$

The mean μ and the variance σ^2 are the two parameters that need to be estimated.

We can read off the standard error of $\vec{\theta}$ from the square roots of the diagonal elements of the matrix Σ. Note that these are only correct asymptotically and are hard to calculate in finite samples.

We know that the likelihood function is:

$$L(\mu, \sigma^2, x_1, \ldots, y_n) = L(\vec{\theta}, \vec{x}) = \frac{1}{(\sqrt{2\pi\sigma^2})^2} e^{-\frac{1}{2}\sum_{j=1}^{n}\frac{(x_j-\mu)^2}{\sigma^2}} \tag{5.7.1329}$$

and hence (for recall):

$$\ln(L(\vec{\theta}, \vec{x})) = \mathcal{L}(\vec{\theta}) = -\frac{n}{2}\log(2\pi) - \frac{n}{2}\log(\sigma^2) - \frac{1}{2\sigma^2}\sum_{j=1}^{n}(x_j-\mu)^2 \tag{5.7.1330}$$

The likelihood and their solution are for recall:

$$\begin{aligned}
\frac{\partial \ln(L(\vec{\theta})}{\partial \mu} &= \frac{\mathcal{L}(\vec{\theta})}{\partial \mu} = \frac{1}{\sigma^2}\sum_{j=1}^{n}(x_t-\mu) = 0 \Rightarrow \hat{\mu} = \frac{1}{n}\sum_{j=1}^{n} x_j \\
\frac{\partial \ln(L(\vec{\theta})}{\partial \sigma^2} &= \frac{\mathcal{L}(\vec{\theta})}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{1}{2\sigma^2}\sum_{j=1}^{n}(x_j-\mu)^2 = 0 \Rightarrow \hat{\sigma}^2 = \frac{1}{n}\sum_{i=1}^{n}(x_j-\hat{\mu})^2
\end{aligned} \tag{5.7.1331}$$

Now let us calculate the Hessian of $\hat{\theta} = (\hat{\mu}, \hat{\sigma}^2$, that is the Hessian of $\mathcal{L}(\vec{\theta})$. We have to compute 4 components of the matrix as the likelihood has 2 parameters ($2 \times 2 = 4$) and the out-diagonal components are equal assuming the Schwarz theorem applies. Then:

$$\begin{aligned}
\frac{\partial^2\mathcal{L}(\vec{\theta})}{\partial\mu^2} &= -\frac{n}{\sigma^2}\\
\frac{\partial^2\mathcal{L}(\vec{\theta})}{\partial\sigma^2} &= \frac{n}{2\sigma^4}-\frac{1}{\sigma^6}\sum_{j=1}^{n}(x_j-\mu)^2\\
\frac{\partial^2\mathcal{L}(\vec{\theta})}{\partial\sigma^2\partial\mu} &= -\frac{1}{\sigma^4}\sum_{j=1}^{n}(x_j-\mu)
\end{aligned}\tag{5.7.1332}$$

When evaluated at $\hat{\vec{\theta}}$:

$$\begin{aligned}
\left.\frac{\partial^2\mathcal{L}(\vec{\theta})}{\partial\mu^2}\right|_{\vec{\theta}=\hat{\vec{\theta}}} &= -\frac{n}{\hat{\sigma}^2}\\
\left.\frac{\partial^2\mathcal{L}(\vec{\theta})}{\partial\sigma^2}\right|_{\vec{\theta}=\hat{\vec{\theta}}} &= \frac{n}{2\hat{\sigma}^4}-\frac{1}{\hat{\sigma}^6}\sum_{j=1}^{n}(x_j-\hat{\mu})^2=\frac{n}{2\hat{\sigma}^4}-\frac{n\hat{\sigma}^2}{\hat{\sigma}^6}=-\frac{n}{2\hat{\sigma}^2}\\
\left.\frac{\partial^2\mathcal{L}(\vec{\theta})}{\partial\sigma^2\partial\mu}\right|_{\vec{\theta}} &= -\frac{1}{\hat{\sigma}^4}\sum_{j=1}^{n}(x_j-\mu)=0
\end{aligned}\tag{5.7.1333}$$

Hence:

$$H(\hat{\vec{\theta}})=\begin{bmatrix}-\dfrac{n}{\hat{\sigma}^2} & 0\\ 0 & -\dfrac{n}{2\hat{\sigma}^4}\end{bmatrix}\tag{5.7.1334}$$

We have also:

$$H(\vec{\theta})=\begin{bmatrix}-\dfrac{n}{\sigma^2} & -\dfrac{1}{\sigma^4}\displaystyle\sum_{j=1}^{n}(x_j-\mu)\\ -\dfrac{1}{\sigma^4}\displaystyle\sum_{j=1}^{n}(x_j-\mu) & \dfrac{n}{2\sigma^4}-\dfrac{1}{\sigma^6}\displaystyle\sum_{j=1}^{n}(x_j-\hat{\mu})^2\end{bmatrix}\tag{5.7.1335}$$

We have:

$$\begin{aligned}
\mathrm{E}\left[-\frac{n}{\sigma^2}\right] &= -\frac{n}{\sigma^2}\\
\mathrm{E}\left[-\frac{1}{\sigma^4}\sum_{j=1}^{n}(x_j-\mu)\right] &= -\frac{1}{\sigma^4}\sum_{j=1}^{n}\mathrm{E}(x_j-\mu)=0\\
\mathrm{E}\left[\frac{n}{2\sigma^4}-\frac{1}{\sigma^6}\sum_{j=1}^{n}(x_j-\hat{\mu})^2\right] &= \frac{n}{2\sigma^4}-\frac{1}{\sigma^6}\sum_{j=1}^{n}\mathrm{E}(x_j-\hat{\mu})^2=\frac{n}{2\sigma^4}-\frac{n\sigma^2}{\sigma^6}=-\frac{n}{2\sigma^4}
\end{aligned}\tag{5.7.1336}$$

Hence, the Fisher information matrix is given by:

$$\mathcal{I}(\vec{\theta})=-\mathrm{E}(H(\vec{\theta}))=\begin{bmatrix}\dfrac{n}{\sigma^2} & 0\\ 0 & \dfrac{n}{2\sigma^4}\end{bmatrix} \tag{5.7.1337}$$

Matrix inversion gives us also (see section Linear Algebra page 1980):

$$\Sigma(\vec{\theta})\cong-\mathrm{E}(H^{-1})=\dfrac{1}{\dfrac{n}{\sigma^2}\dfrac{n}{2\sigma^4}-0\cdot 0}\begin{bmatrix}\dfrac{n}{2\sigma^4} & 0\\ 0 & \dfrac{n}{\sigma^2}\end{bmatrix}=\begin{bmatrix}\dfrac{\sigma^2}{n} & 0\\ 0 & \dfrac{2\sigma^4}{n}\end{bmatrix} \tag{5.7.1338}$$

Hence:

$$\mathrm{V}(\vec{\theta})=\begin{pmatrix}\dfrac{\sigma^2}{n}\\ \dfrac{2\sigma^4}{n}\end{pmatrix} \tag{5.7.1339}$$

Now let us recall that during our proof of the central limit theorem, we have proved that (page 938):

$$Z_n=\dfrac{\hat{\mu}-\mu}{\sigma/\sqrt{n}}\cong\mathcal{N}(0,1) \tag{5.7.1340}$$

Therefore:

$$\sqrt{n}\,(\hat{\mu}-\mu)=\mathcal{N}(0,\sigma) \tag{5.7.1341}$$

Now instead of the estimator $\hat{\mu}$, let us consider the estimate of the score function (the σ is obviously the same as the previous relation):

$$\sqrt{n}\left(\hat{\mathcal{S}}_i(\theta)-\mathcal{S}_i(\theta)\right)=\mathcal{N}(0,\sigma) \tag{5.7.1342}$$

Now we consider that $\hat{\mathcal{S}}$ at the true value of θ (i.e. θ_0) is not zero as it is an estimator (but it's however probable near zero)! But $\mathcal{S}$ is however zero at θ_0. Then we have:

$$\sqrt{n}\left(\hat{\mathcal{S}}_i(\theta_0)-\mathcal{S}_i(\theta_0)\right)=\sqrt{n}\left(\hat{\mathcal{S}}_i(\theta_0)-0\right)=\mathcal{N}(0,\sigma) \tag{5.7.1343}$$

Hence:

$$\sqrt{n}\hat{\mathcal{S}}_i(\theta_0)=\mathcal{N}(0,\sigma) \tag{5.7.1344}$$

Or in vector form:

$$\sqrt{n}\vec{\hat{\mathcal{S}}}(\theta_0)=\mathcal{N}\left(0,\Sigma(\vec{\hat{\mathcal{S}}})\right) \tag{5.7.1345}$$

With explicitly, by construction of the variance-covariance matrix (for the special case of 2×2 to simplify the example):

$$\Sigma(\vec{\hat{\mathcal{S}}})=\begin{bmatrix}\sigma^2_{\hat{\mathcal{S}}_1} & \sigma_{\hat{\mathcal{S}}_1}\sigma^2_{\hat{\mathcal{S}}_2}\\ \sigma_{\hat{\mathcal{S}}_1}\sigma_{\hat{\mathcal{S}}_2} & \sigma^2_{\hat{\mathcal{S}}_2}\end{bmatrix}=\begin{bmatrix}\mathrm{E}((\hat{\mathcal{S}}_1-\mathcal{S}_1)^2) & \mathrm{E}((\hat{\mathcal{S}}_1-\mathcal{S}_1)(\hat{\mathcal{S}}_2-\mathcal{S}_2))\\ \mathrm{E}((\hat{\mathcal{S}}_1-\mathcal{S}_1)(\hat{\mathcal{S}}_2-\mathcal{S}_2)) & \mathrm{E}((\hat{\mathcal{S}}_2-\mathcal{S}_2)^2)\end{bmatrix} \tag{5.7.1346}$$

However, estimated at $\vec{\theta}_0$ the true values $\mathcal{S}_1$ and $\mathcal{S}_2$ are equal to zero. Then the variance-covariance matrix reduces to:

$$\Sigma(\vec{\hat{\mathcal{S}}})=\begin{bmatrix}\mathrm{E}(\hat{\mathcal{S}}_1^2) & \mathrm{E}(\hat{\mathcal{S}}_1\hat{\mathcal{S}}_2)\\ \mathrm{E}(\hat{\mathcal{S}}_1\hat{\mathcal{S}}_2) & \mathrm{E}(\hat{\mathcal{S}}_2^2)\end{bmatrix}=\mathrm{E}\left(\begin{bmatrix}\hat{\mathcal{S}}_1^2 & \hat{\mathcal{S}}_1\hat{\mathcal{S}}_2\\ \hat{\mathcal{S}}_1\hat{\mathcal{S}}_2 & \hat{\mathcal{S}}_2^2\end{bmatrix}\right) \tag{5.7.1347}$$

Or by expliciting the score functions:

$$\Sigma(\vec{\hat{\mathcal{S}}})=\mathrm{E}\left(\begin{bmatrix}\hat{\mathcal{S}}_1^2 & \hat{\mathcal{S}}_1\hat{\mathcal{S}}_2\\ \hat{\mathcal{S}}_1\hat{\mathcal{S}}_2 & \hat{\mathcal{S}}_2^2\end{bmatrix}\right)=\mathrm{E}\left(\begin{bmatrix}\left(\dfrac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_1}\right)^2 & \dfrac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_1}\dfrac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_2}\\ \dfrac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_1}\dfrac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_2} & \left(\dfrac{\partial\mathcal{L}(\vec{x},\vec{\theta})}{\partial\theta_2}\right)^2\end{bmatrix}\right) \tag{5.7.1348}$$

We recognize here the Fisher information matrix! Therefore:

$$\Sigma(\vec{\hat{\mathcal{S}}})=\begin{bmatrix}\sigma_{\hat{\mathcal{S}}_1}^2 & \sigma_{\hat{\mathcal{S}}_1}\sigma_{\hat{\mathcal{S}}_2}^2\\ \sigma_{\hat{\mathcal{S}}_1}\sigma_{\hat{\mathcal{S}}_2} & \sigma_{\hat{\mathcal{S}}_2}^2\end{bmatrix}=\mathcal{I}(\vec{\theta}) \tag{5.7.1349}$$

And so finally:

$$\sqrt{n}\vec{\hat{\mathcal{S}}}(\theta_0)=\mathcal{N}(0,\mathcal{I}(\vec{\theta})) \tag{5.7.1350}$$

5.7.8 Finite Population Correction Factor

Now we prove another result which we will be required in some statistical tests that we will see later.

Suppose we have a population of N individuals that we represent by the set $\{1,2,\ldots,N\}$ and a random variable X which is an application of $\{1,2,\ldots,N\}$ in $\mathbb{R}$. We denote by $x_i=X(i)$. The mean of X is thus given by:

$$\mu=\frac{1}{N}\sum_{i=1}^{N}x_i \tag{5.7.1351}$$

Remember the variance of X is by definition:

$$\sigma=\frac{1}{N}\sum_{i=1}^{N}(x_i-\mu)^2 \tag{5.7.1352}$$

Now we consider the set E of samples of size n taken in $\{1,2,\ldots,N\}$ with $0<n<N$. Each individual has a probability of being drawn equal to:

$$\frac{1}{N}\frac{1}{N-1}\cdot\ldots\cdot\frac{1}{N-(n-1)}=\frac{(N-n)!}{N!} \tag{5.7.1353}$$

We are interested in the random variable $\bar{X}$ defined on E and that equal to the sample mean. More specifically:

$$\bar{X}(i_1,\ldots,i_n)=\frac{1}{n}\sum_{k=1}^{n}x_{i_k} \qquad (5.7.1354)$$

To calculate the variance $\text{V}(\bar{X})$, we will $\bar{X}$ express as a sum of random variables. Indeed, if we define the variables X_k with $k=1\ldots N$ by:

$$X_k(i_1,\ldots,i_n)=\begin{cases}x_k \text{ if } k\in\{i_1,\ldots,i_n\}\\ 0 \text{ otherwise}\end{cases} \qquad (5.7.1355)$$

We have naturally by the previous definition (see with caution the sum limits!):

$$\bar{X}=\frac{1}{n}\sum_{k=1}^{N}X_k \qquad (5.7.1356)$$

and thus we get:

$$\text{V}(\bar{X})=\frac{\sigma}{n}=\frac{1}{n}\left(\sum_{k=1}^{N}\text{V}(X_k)+\sum_{i\neq j}^{N}\text{cov}(X_i,X_j)\right) \qquad (5.7.1357)$$

The random variables X_k are not independent in pairs, in fact as we shall see, their covariances are not zero if N is finite. Otherwise (zero covariance), we find a result already proved earlier:

$$\text{V}(\bar{X})=\sigma_{\bar{X}}=\frac{\sigma^2}{n} \qquad (5.7.1358)$$

So we need to calculate the variances $\text{V}(X)$ and covariances $\text{cov}(X_i,X_j)$.

For this purpose we will use the Huygens relation and we will start by calculating the mean $\text{E}(X_k)$:

$$\text{E}(X_k)=P(X_k=x_k)x_k \qquad (5.7.1359)$$

But $P(X_k=x_k)$ is the probability that a sample contains k. This probability is obviously equal to n/N and therefore:

$$\text{E}(X_k)=P(X_k=x_k)x_k=\frac{n}{N}x_k \qquad (5.7.1360)$$

Similarly we obtain:

$$\text{E}(X_k^2)=P(X_k=x_k)x_k=\frac{n}{N}x_k^2 \qquad (5.7.1361)$$

We can therefore calculate the variance $\text{V}(X_k)$:

$$\text{V}(X_k)=\text{E}(X_k^2)-\text{E}(X_k)^2=\frac{n}{N}x_k^2-\left(\frac{n}{N}x_k\right)^2=\frac{n(N-n)}{N^2}x_k^2 \qquad (5.7.1362)$$

To calculate the covariances we need now to calculate the means $\text{E}(X_iX_j)$:

$$\text{E}(X_iX_j)=P(X_i=x_i,X_j=x_j)x_ix_j \qquad (5.7.1363)$$

But $P(X_i = x_i, X_j = x_j)$ is the probability that a sample contains i and j. This probability is obviously given by:

$$\frac{n}{N}\frac{n-1}{N-1} \tag{5.7.1364}$$

and therefore:

$$\mathrm{E}(X_iX_j) = \frac{n(n-1)}{N(N-1)}x_ix_j \tag{5.7.1365}$$

We can now compute the covariance:

$$\mathrm{cov}(X_i,X_j) = \mathrm{E}(X_iX_j) - \mathrm{E}(X_i)\mathrm{E}(X_j) = \frac{n(n-1)}{N(N-1)}x_ix_j - \frac{n^2}{N^2}x_ix_j = -\frac{n(N-n)}{N^2(N-1)}x_ix_j \tag{5.7.1366}$$

We are now able to calculate $\mathrm{V}(\bar{X})$:

$$\mathrm{V}(\bar{X}) = \frac{1}{n}\left(\sum_{k=1}^{N}\mathrm{V}(X_k) + \sum_{i\neq j}^{N}\mathrm{cov}(X_i,X_j)\right) = \frac{1}{n}\left(\frac{n(N-n)}{N^2}\sum_{k=1}^{N}x_k^2 - \frac{n(N-n)}{N^2(N-1)}\sum_{i\neq j}^{N}x_ix_j\right) \tag{5.7.1367}$$

Using Huygens theorem we get:

$$\mathrm{V}(X_k) = \sigma^2 = \mathrm{E}(X_k^2) - \mathrm{E}(X_k)^2 = \mathrm{E}(X_k^2) - \mu^2 = \mathrm{E}(X_k^2) - \mu^2 \Leftrightarrow \sigma^2 + \mu^2 = \mathrm{E}(X_k^2) \tag{5.7.1368}$$

Using the result proved above and previous relation:

$$\mathrm{E}(X_k^2) = \frac{n}{N}x_k^2 = \sigma^2 + \mu^2 \tag{5.7.1369}$$

Therefore:

$$x_k^2 = \frac{N}{n}\sigma^2 + \frac{N}{n}\mu^2 \Leftrightarrow \sum_{k=1}^{N}x_k^2 = \frac{N^2}{n}\left(\sigma^2+\mu^2\right) \tag{5.7.1370}$$

For the double sum $\sum_{i\neq j}^{N}x_ix_j$, we have:

$$\begin{aligned}\sum_{i\neq j}^{N}x_ix_j &= \sum_{i=1}^{N}x_i(x_1+\ldots+x_{i-1}+x_{i+1}+\ldots+x_N) = \sum_{i=1}^{N}x_i(N\mu - x_i)\\ &= N\mu\sum_{i=1}^{N}x_i - \sum_{i=1}^{N}x_i^2 = N\mu N\mu - \sum_{i=1}^{N}x_i^2 = N^2\mu^2 - \sum_{i=1}^{N}x_i^2\\ &= N^2\mu^2 - \frac{N^2}{n}\left(\sigma^2+\mu^2\right)\end{aligned} \tag{5.7.1371}$$

Therefore:

$$\begin{aligned}
\mathrm{V}(\bar{X}) &= \frac{1}{n}\left[\frac{n(N-n)}{N^2}\frac{N^2}{n}\left(\sigma^2+\mu^2\right)-\frac{n(N-n)}{N^2(N-1)}\left(N^2\mu^2-\frac{N^2}{n}\left(\sigma^2+\mu^2\right)\right)\right]\\
&= \frac{1}{n}\left[(N-n)\left(\sigma^2+\mu^2\right)-\frac{n(N-n)}{N-1}\left(\mu^2-\frac{1}{n}\left(\sigma^2+\mu^2\right)\right)\right]\\
&= \frac{1}{n}\left((N-n)\left(\sigma^2+\mu^2\right)-\frac{n(N-n)}{N-1}\mu^2+\frac{N-n}{N-1}\sigma^2+\frac{N-n}{N-1}\mu^2\right)\\
&= \frac{1}{n}\left((N-n)\sigma^2+\frac{N-n}{N-1}\sigma^2+\mu^2\left(\frac{N-n}{N-1}-\frac{n(N-n)}{N-1}+(N-n)\right)\right)\\
&= \frac{1}{n}\left((N-n)\sigma^2+\frac{N-n}{N-1}\sigma^2+\mu^2\left(\frac{-nN+n^2+N^2-nN}{N-1}\right)\right)\\
&= \frac{1}{n}\left((N-n)\sigma^2+\frac{N-n}{N-1}\sigma^2+\mu^2\frac{(N-n)^2}{N-1}\right)\\
&= \frac{1}{n}\left(\frac{N(N-n)}{N-1}\sigma^2+\mu^2\frac{(N-n)^2}{N-1}\right)\\
&= ..???.. = \sigma^2\frac{N-n}{n(N-1)}
\end{aligned}\tag{5.7.1372}$$

Thus:

$$\boxed{\sigma_{\bar{X}}=\sqrt{\mathrm{V}(\bar{X})}=\frac{\sigma}{\sqrt{n}}\sqrt{\frac{N-n}{N-1}}}\tag{5.7.1373}$$

The famous factor:

$$\text{fpc}=\sqrt{\frac{N-n}{N-1}}\leq 1\tag{5.7.1374}$$

that we have already encountered during our study the hypergeometric distribution is named "finite correction factor (on finite population)" and has the effect of reducing the standard error especially as n is large. This factor is less than 1, so the variance of the hypergeometric is always less than that of the corresponding binomial. This makes sense because the draws are made without replacement in the hypergeometric distribution.

If the sample is relatively large (more than 5% of the population), it is sometimes customary to use this correction factor.

In the science of survey, we can conclude that for the "random sample without replacement (RSWOR)" and for "random sample with replacement (RSWR)" the average is most of times given by:

$$\hat{\mu}_X=\frac{1}{n}\sum_{i=1}^{n}x_i\tag{5.7.1375}$$

but for the standard deviation:

$$\hat{\sigma}_{\text{RSWR}}=\sqrt{\mathrm{V}(\bar{X}_n)}=\frac{\sigma_N^2}{\sqrt{n}}\qquad\hat{\sigma}_{\text{RSWOR}}=\sqrt{\mathrm{V}(\bar{X}_n)}=\frac{\sigma_N^2}{\sqrt{n}}\sqrt{\frac{N-n}{N-1}}\tag{5.7.1376}$$

where the correction factor is sometimes approximated by:

$$\text{fpc} \cong \sqrt{\frac{N-n}{N}} \tag{5.7.1377}$$

5.7.9 Confidence Intervals (inference)

Until now we have always determined the likelihood estimators or simple estimators (variance, standard deviation) from theoretical statistics distributions or measured on an entire population of data. But now that we have covered descriptive statistics, probability and sampling, we are ready to make "frequentist inference" and "bayesian inference" from our sample data to our population of interest.

In statistical frequentist inference, we take what we know from the sample, apply the underlying theory of sampling (central limit theorem) to make statements about our population of interest. We make estimates about the population through the use of the sample data. Estimates can either be point estimates or interval estimates. In statistical Bayesian inference, we take the likelihood knowledge we have on the data and the prior on some parameters to infer a posterior distribution having new "hyperparameters".

quote 5.7:848.#47

> *Being a statistician means never having to say you are certain!*
>
> ?

5.7.9.1 Frequentist Inference

Definition (#5.7.135): A "confidence interval" (C.I.) in frequentist inference is a pair of numbers (in the univariate case) that defines (a priori) the range of possible values with a certain cumulative probability of the distribution of a given estimator from a sample of an experience (the range of the statistical indicator being usually calculated using real measured parameters). In other words, the C.I. is a collection of intervals with a given percentage (probability) of them containing the true parameter!

Formally, let y be a random sample from a probability distributions governed by a parameter of interest θ and quantities not of interest φ. A confidence interval for θ is defined as an interval $[u(y), v(y)]$ determined by the random variables $u(y)$ and $v(y)$ with the property:

$$P(u(y) < \theta < v(y) \mid \theta, \varphi) = \gamma \qquad \forall(\theta, \varphi) \tag{5.7.1378}$$

where $\gamma = 1 - \alpha$ is the confidence level.

So we must say: The a priori probability that our method produces confidence intervals that will contain θ is $1 - \alpha$.

But we should never say: The probability that this confidence interval we produced does contain θ is $1 - \alpha$.

Remark

The confidence interval is often confused with the "Bayesian credibility interval" that is an interval within which an unobserved parameter value falls with a particular probability. It is an interval in the domain of a posterior probability distribution or a predictive distribution (the generalisation to multivariate problems is the "credible region").

Textbook authors and proponents of confidence intervals bridge the gap seamlessly by claiming that confidence intervals have three desirable properties: first, that the confidence coefficient can be read as a measure of the uncertainty one should have that the interval contains the parameter; second, that the CI width is a measure of estimation uncertainty; and third, that the interval contains the "likely" or "reasonable" values for the parameter. These all involve reasoning about the parameter from the observed data: that is, they are "post-data" inferences.

These interpretations of confidence intervals are not correct. We name the mistake these authors have made the "Fundamental Confidence Fallacy" (FCF) because it seems to flow naturally from the definition of the confidence interval (see [436]).

The reasoning behind the Fundamental Confidence Fallacy seems plausible: on a given sample, we could get any one of the possible confidence intervals. If 95% of the possible confidence intervals contain the true value, without any other information it seems reasonable to say that we have 95% certainty that we obtained one of the confidence intervals that contain the true value. This interpretation is suggested by the name "confidence interval" itself: the word "confident", in lay use, is closely related to concepts of plausibility and belief. The name "confidence interval" — rather than, for instance, the more accurate "coverage procedure" — encourages the Fundamental Confidence Fallacy.

So if the confidence intervals of two parameters overlap you can't conclude that these parameters are not significantly different from each other! And that's because if you construct a hundred 95% confidence intervals, then about 95 of these intervals will contain the population value (you must always keep in mind that you work with statistical objects!!!!). So the specific values of a calculated confidence intervals should rigorously not be directly interpreted!

In short, this is what you need to remember when comparing two confidence intervals:

1. When two confidence intervals of a given parameter do not overlap, the difference between the two parameters will be significant.
2. When two confidence intervals of a given parameter do overlap, the difference between the two parameters can be significant or non-significant.

Keep in mind for example when the parameter is the mean, that standard errors of means are not the same as the standard errors of differences of means!

Figure 5.158: Example of confidence intervals that have interested million of peoples not so far ago in the past...

We now turn to the task that consists naturally to ask ourselves what must be the sample sizes of our measured data to have some validity for our estimators or even to which confidence interval correspond a given standard deviation or quantile in a Normal centered reduced distribution (for large samples), in a chi-square distribution, Student distribution or Fisher distribution (we will see the last two cases of small sample sizes further below during our study of ANalysis Of VAriance, i.e. ANOVA) when the mean or variance are known or unknown respectively on all or part of the given population.

It is important to know that these confidence intervals often use the central limit theorem that will be proved further below (to avoid any possible frustration) and the developments that we will do now are also useful in the field of (a posteriori) Hypotheses Tests that have a major role in statistics and therefore indirectly in all fields of science!!!

Finally, it could be useful to indicate that a large numbers of organizations (private or institutional) make false statistics because the assumptions and conditions of use of these confidence intervals (verbatim hypotheses tests) are not rigorously verified or simply omitted or worse, the whole base (measurements) is not collected in the rules of art (reliability of the data collection and reproducibility protocols not validated by scientific peer).

The reader must also know that we have put many other confidence interval techniques detailed proofs related for example for regression techniques in the section of Theoretical Computing page 6316.

Remark

The practitioner should be very careful about the calculation of confidence intervals and the use of hypothesis testing in practice. This is why, to avoid trivial usage error or interpretation error, it is important to refer to the following international standards eg: ISO 2602:1980 (*Statistical interpretation of test results - Estimation of the mean - Confidence interval*), ISO 2854:1976 (*Statistical interpretation of data - Techniques of estimation and tests relating to means and variances*), ISO 3301:1975 (*Statistical interpretation of data - Comparison of two means in the case of paired observations*), ISO 3494:1976 (*Statistical interpretation of data - Effectiveness of tests relating to means and variances*), ISO 5479:1997 (*Statistical interpretation of data - Tests for departure from the Normal distribution*), ISO 10725:2000 + ISO 11648-1:2003 + ISO 11648-2:2001 (*Sampling plans and procedures for acceptance for control of bulk materials*), ISO 11453:1996 (*Statistical interpretation of data - Tests and confidence intervals relating to proportions*), ISO 16269-4:2010 (*Statistical interpretation of data - Detection and treatment of outliers*), ISO 16269-6:2005 (*Statistical interpretation of data - Determination of statistical tolerance intervals*), ISO 16269-8:2004 (*Statistical Interpretation of data - Determination of prediction intervals*), ISO / TR 18532:2009 (*Guidelines for the application of statistical quality and industrial standards*).

Figure 5.159: **Cartography of statistics standards**

Caution! The reader must not expect to find in this textbook a detailed derivation of the almost 500 parametric, non-parametric and bayesian hypothetical tests and their respective confidence intervals! It would take tenth of thousand of pages to do such a work. However we provide in the section of Numerical Methods at page 6775, an exhaustive list of all these kind of tests and even an illustration (see page 6770) categorizing them by family (there may be some categorization errors!).

5.7.9.1.1 C.I. on the Mean with known theoretical Variance

Let's start with the simplest and most common case that is the determination of the number of individuals to have some confidence in the average of the measurements of a random variable assumed to follow a Normal distribution.

First let us recall that we showed at the beginning of this chapter that the standard error (standard deviation of the mean) was under the assumptions of independent and identically distributed variables (i.i.d.):

$$\sigma_{\bar{X}}=\frac{\sigma}{\sqrt{n}} \tag{5.7.1379}$$

Now, before we go any further, consider X as a random variable following a Normal distribution with mean μ and standard deviation σ. We would like that the random variable has for example 95% cumulative probability of being in a given bounded symmetric interval. Which is therefore expressed as follows:

$$P(\mu-\delta\leqslant X\leqslant\mu+\delta)=0.95 \tag{5.7.1380}$$

Remark

Therefore with a confidence interval of 95% you will be right a posteriori 19 times out of 20, or any other level of confidence or risk level α (1-confidence level, 5%) that you will be set up in advance (many practitioners recommend in this beginning of the 121st century (holocene calendar) to take a $\alpha=1\%$). On average, your conclusions will therefore be good, but we can never know whether a particular decision is good! If the risk level is very low but the event still occurs, specialists then speak about a "large deviation" or a "black swan". Management of outliers is addressed in ISO 16269-4:2010 *Detection and treatment of outliers* that any engineer doing business statistics has to follow.

By centering and reducing the random variable:

$$P\left(-\frac{\delta}{\sigma}\leqslant\frac{X-\mu}{\sigma}\leqslant\frac{\delta}{\sigma}\right)=0.95 \tag{5.7.1381}$$

Let us now write Y the reduced centered variable:

$$P\left(-\frac{\delta}{\sigma}\leqslant Y\right)-P\left(Y\geqslant\frac{\delta}{\sigma}\right)=0.95 \tag{5.7.1382}$$

Since the Normal centered reduced distribution is symmetric:

$$1-2P\left(Y\geqslant\frac{\delta}{\sigma}\right)=0.95 \tag{5.7.1383}$$

Therefore:

$$P\left(Y\geqslant\frac{\delta}{\sigma}\right)=0.025 \tag{5.7.1384}$$

From there reading statistical tables of the standard Normal distribution (or by using a simple spreadsheet software), we have to satisfy the equality that:

$$\frac{\delta}{\sigma}\cong 1.96 \quad\Leftrightarrow\quad \delta\cong 1.96\sigma \tag{5.7.1385}$$

Which can easily be obtained with Microsoft® Excel® 11.8346 by using the function:

```
=-NORMSINV((1-0.95)/2)
```

As noted in the traditional way in the general case other than the 95% one (Z is the random variable corresponding to the half quantile of the chosen threshold of the standard Normal distribution):

$$\delta\cong Z\sigma \tag{5.7.1386}$$

Now, consider that the variable X on which we wish to make statistical inference is the average (and we show later that it follows a Normal distribution centered reduced distribution). Therefore:

$$\delta\cong Z\sigma=Z\frac{\sigma}{\sqrt{n}} \tag{5.7.1387}$$

Then we get:

$$n\cong\frac{Z^2\sigma^2}{\delta^2} \tag{5.7.1388}$$

from which we obviously take (normally...) the upper integer value...

The latter notation is usually written in the following way highlighting better the width of the confidence interval of an underlying threshold level[43] α:

$$\boxed{n\cong\left\lceil\left(\frac{Z_{\alpha/2}\sigma}{\delta}\right)^2\right\rceil} \tag{5.7.1389}$$

Relation named "sample size estimation by Normal distribution".

---

[43] Don't forget that in this textbook we write $Z_{\alpha/2}$ where most authors write $Z_{1-\alpha/2}$

Remark

Calculating an appropriate sample size for typically a clinical trial is like walking on a knife edge for the statistician: too low a sample size and the study risks being unable to detect a difference between treatment and the control group, too large a sample size and we will have a "overpowering" of the study that can lead to several issues theoretical issues (p-hacking) that might cause the study to not be as effective or interpretable, and to potentially become unethical.

Thus, we now know the number of individuals we must have to ensure to get a given precision interval δ (margin of error) around the mean and that for a given percentage measures are in this range and assuming the theoretical standard deviation σ is known (or imposed) in advance (typically used in quality engineering or surveys).

In the case of polls / surveys where the sample population is large enough, then we can introduce the population correction factor fpc that we proved earlier above (we speak then of SPWR for "survey plan without replacement"). Then it comes by taking the approximation of the fpc:

$$\begin{aligned} n &\cong \left(\frac{Z_{\alpha/2}\sqrt{1-\dfrac{n}{N}}\sigma}{\delta}\right)^2=\frac{Z_{\alpha/2}^2\left(1-\dfrac{n}{N}\right)\sigma^2}{\delta^2}\\ \Rightarrow n&\left(1+\frac{Z_{\alpha/2}^2\sigma^2}{N}\right)\cong\frac{Z_{\alpha/2}^2\sigma^2}{\delta^2}\\ \Rightarrow n&\cong\frac{Z_{\alpha/2}^2\sigma^2}{\delta^2\left(1+\dfrac{Z_{\alpha/2}^2\sigma^2}{N}\right)}=\frac{NZ_{\alpha/2}^2\sigma^2}{\delta^2 N+Z_{\alpha/2}^2\sigma^2}\end{aligned} \quad (5.7.1390)$$

In other words, we can calculate the number n of individuals to measure to ensure a given confidence interval (associated to the quantile Z) of the measured average assuming the theoretical standard deviation known (or imposed) and wishing a precision δ in absolute value of the mean.

However ... in reality, the variable Z comes from the central limit theorem (see below) that gives for a large sample size (approximately):

$$\boxed{Z=Z_n=\frac{M_n-\mu}{\sigma/\sqrt{n}}=\frac{\bar{X}-\mu}{\sigma/\sqrt{n}}} \quad (5.7.1391)$$

Rearranging we get then:

$$\mu=\bar{X}-Z\frac{\sigma}{\sqrt{n}} \quad (5.7.1392)$$

and as Z can be negative or positive then it is more logic to write this as:

$$\mu=\bar{X}\pm Z\frac{\sigma}{\sqrt{n}} \quad (5.7.1393)$$

Thus:

$$\bar{X}-Z\frac{\sigma}{\sqrt{n}}\leqslant\mu\leqslant\bar{X}+Z\frac{\sigma}{\sqrt{n}} \quad (5.7.1394)$$

That engineers sometimes write:

$$\text{LCL} \leqslant \mu \leqslant \text{UCL} \tag{5.7.1395}$$

where LCL is the lower confidence limit and UCL the upper confidence limit. This is the Six Sigma terminology (see section Industrial Engineering 8674).

And we have seen earlier that for a confidence interval of 95% we have $Z = 1.96$. And since the Normal distribution is symmetric:

$$95\% = 1 - 5\% = 1 - \alpha = 1 - 2 \cdot 2.5\% = 1 - 2 \cdot 0.025 \tag{5.7.1396}$$

Thus we finally write[44] the "one sample Z test":

$$\boxed{\bar{X} - Z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \leqslant \mu \leqslant \bar{X} + Z_{\alpha/2}\frac{\sigma}{\sqrt{n}}} \tag{5.7.1397}$$

where we define for all tests having the same structure, the "margin error" by:

$$\text{ME} = Z_{\alpha/2}\frac{\sigma}{\sqrt{n}} \tag{5.7.1398}$$

If the elements sampled are not independent then we have to write obviously:

$$\boxed{\bar{X} - Z_{\alpha/2}\frac{\sigma}{\sqrt{n}}\text{fpc} \leqslant \mu \leqslant \bar{X} + Z_{\alpha/2}\frac{\sigma}{\sqrt{n}}\text{fpc}} \tag{5.7.1399}$$

where for recall as proven earlier:

$$\text{fpc} = \sqrt{\frac{N-n}{N-1}} \tag{5.7.1400}$$

is the finite population correction factor.

As we have already mentioned, and we will prove a little further, the arithmetic reduced centered mean of a series of independent and identically distributed random variables with finite variance asymptotically follows a standard Normal distribution, this is why the confidence interval above is very general! This is why we sometimes speak of "asymptotic confidence interval of the mean".

These intervals obviously have for origin the fact that we work very often in statistics with samples and not the entire available population. The selected sampling thus affects the value of the punctual estimator. We then speak of "sampling fluctuation".

In the particular case of an IC (confidence interval) at 95%, the last relation will be written:

$$\bar{X} - Z_{0.025}\frac{\sigma}{\sqrt{n}} \leqslant \mu \leqslant \bar{X} + Z_{0.025}\frac{\sigma}{\sqrt{n}} \tag{5.7.1401}$$

Sometimes we find the prior-previous inequality in the following equivalent notation:

$$\bar{X} - Z_{\alpha/2}\sigma_{\bar{X}} \leqslant \mu \leqslant \bar{X} + Z_{\alpha/2}\sigma_{\bar{X}} \tag{5.7.1402}$$

---

[44] Don't forget that in this textbook we write $Z_{\alpha/2}$ where most authors write $Z_{1-\alpha/2}$

or more rarely with the following general notation (for all intervals):

$$\bar{X}-\text{ME}\leqslant\mu\leqslant\bar{X}+\text{ME}\qquad(5.7.1403)$$

where ME stands for "margin of error".

We are thus now able to estimate population sizes needed to obtain a certain level of confidence α in an outcome or to estimate the confidence interval in which is the theoretical mean knowing the experimental (empirical) average and the estimator maximum likelihood of the standard deviation. We can of course therefore also determine the a posteriori probability that the mean is outside a given range ... (one as the other being widely used in the industry).

Finally, note that from the previous result, we deduce immediately the stability property of the Normal distribution (shown above) the following test that we find in many statistical softwares:

$$Z^{\text{calc.}}=\frac{(\bar{X}_2-\bar{X}_1)-(\mu_2-\mu_1)}{\sqrt{\dfrac{\sigma_1^2}{n}+\dfrac{\sigma_2^2}{n}}}\qquad(5.7.1404)$$

named "bilateral Z test on the difference of two means" or also sometimes named "two sample Z test" and with the corresponding confidence interval:

$$\boxed{(\bar{X}_2-\bar{X}_1)-Z_{\alpha/2}\sqrt{\frac{\sigma_1^2}{n}+\frac{\sigma_2^2}{n}}\leq\mu_2-\mu_1\leq(\bar{X}_2-\bar{X}_1)+Z_{\alpha/2}\sqrt{\frac{\sigma_1^2}{n}+\frac{\sigma_2^2}{n}}}\qquad(5.7.1405)$$

And this is not because two means are significantly different that their confidence intervals do not overlap!!!! As shows the graph below obtained with Minitab 16 software where the test-Z of the difference is significant at 95%:

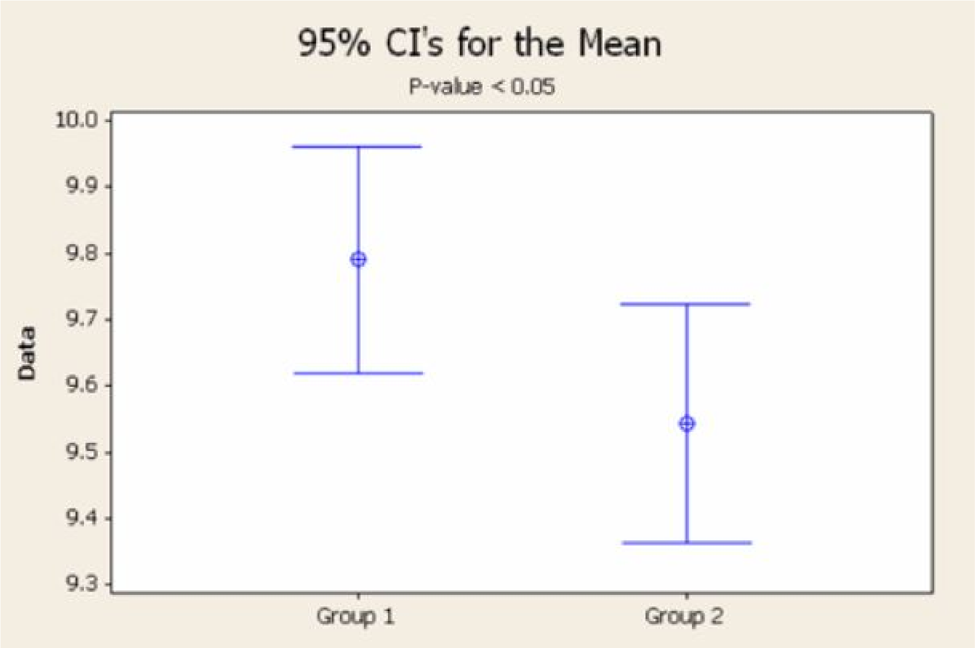

Figure 5.160: **Line plot illustration of the overlay of two 95% confidence intervals (source: Minitab 15)**

while their mean is significantly different to a confidence level of 95%.

Also notice that many people (especially non-scientists) don't understand why a "practical mean difference" is not the same as "statistical mean difference". But the reason is obvious! The first doesn't involve the variance and the second one do! Hence the fact that the second one is more rigorous!!!

Remark

The size of the parent population for the relations developed above does not come into consideration in the calculations of confidence intervals or even not in the sample size, and because it is considered as infinite. So be careful not sometimes not to have sample sizes that are larger than the actual parent population...

5.7.9.1.2 C.I. on the Variance with known theoretical Mean

Let's start by demonstrating a fundamental property of the Chi-square distribution:

If a random variable X follows a Normal centered reduced distribution $X = \mathcal{N}(0,1)$ then its square follows a chi-square distribution of 1 degree of freedom:

$$X^2 = \chi^2(1) \tag{5.7.1406}$$

This result is sometimes named a "Wald statistics" and any statistical test using it directly (we should better speak about a "test family") can be designated under the name "Wald's test" (for a concrete example see further below the Cochran-Mantel-Haenszel test page 1283).

Proof 5.47.9. To prove this property, it suffices to calculate the density of the random X^2 variable with $X = \mathcal{N}(0,1)$. However, if $X = \mathcal{N}(0,1)$ and if we set $Y = X^2$, then for all $y \geq 0$ we get:

$$P(Y \leqslant y) = P(X^2 \leqslant y) = P(-\sqrt{y} \leqslant Y \leqslant \sqrt{y}) \tag{5.7.1407}$$

Since the standard Normal distribution is symmetric about 0 for the random variable X, we can write:

$$P(Y \leqslant y) = 2P(0 \leqslant X \leqslant \sqrt{y}) \tag{5.7.1408}$$

Denoting by Φ the cumulative distribution function of the standard Normal distribution, we have:

$$P(Y \leqslant y) = 2\Phi(\sqrt{y}) - 2 \cdot 0.5 = 2\Phi(\sqrt{y}) - 1 \tag{5.7.1409}$$

and as:

$$\Phi(0) = P(\mathcal{N}(0,1) \leq 0) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{0} e^{-k/2}\mathrm{d}k = 0.5 \tag{5.7.1410}$$

therefore:

$$P(Y \leq y) = 2\Phi(\sqrt{y}) - 2 \cdot 0.5 = 2\Phi(\sqrt{y}) - 1 \tag{5.7.1411}$$

The cumulative distribution function of the random variable $Y = X^2$ is thus given by:

$$P(Y \leq y) = 2\Phi(\sqrt{y}) - 1 \tag{5.7.1412}$$

if y is greater than or equal to zero, null if y is less than zero. We will denote this cumulative distribution $f_Y(y)$ for the further calculations.

Since the density distribution function is the derivative of the cumulative distribution function and X follows a Normal centered reduced distribution so we reduced for the random variable X:

$$P(X = x) = \Phi'(x) = \frac{\mathrm{d}}{\mathrm{d}x}\Phi(x) = \frac{1}{\sqrt{2\pi}}e^{-x^2/2} \tag{5.7.1413}$$

and then it follows for the probability distribution of Y (which is the square of X for reminder!):

$$\frac{\mathrm{d}}{\mathrm{d}y}f_Y(y) = \frac{\mathrm{d}}{\mathrm{d}y}(2\Phi(\sqrt{y}) - 1) = 2\Phi'(\sqrt{y})\frac{\mathrm{d}}{\mathrm{d}y}\sqrt{y} = \frac{1}{\sqrt{y}}\Phi'(\sqrt{y}) = \frac{1}{\sqrt{y}}\frac{1}{\sqrt{2\pi}}e^{-y/2}\frac{1}{\sqrt{2\pi y}}e^{-y/2} \tag{5.7.1414}$$

this last expression corresponds is exactly the relation we obtained during our study of the chi-square distribution imposing a degree of freedom equal to the unit.

The theorem is therefore proved, that is if X follows a Normal centered reduced distribution while its square follows a Chi-square distribution of 1 degree of freedom as:

$$\boxed{\left(X_{\mathcal{N}(0,1)}\right)^2 = \chi^2(1)} \tag{5.7.1415}$$

■ Q.E.D.

This type of relation is used mainly in industrial processes and their control (see section Industrial Engineering page 8934).

Now let us open a parenthesis that is quite important in some linear regression software reports and especially in the curvature test for design of experiment (see section Industrial Engineering page 8780). Let us recall that we have:

$$T_n = \frac{\mathcal{N}(0,1)}{\sqrt{\chi_n^2/n}} \tag{5.7.1416}$$

And we have just prove above that:

$$Z^2 = \frac{\chi_1^2}{1} \tag{5.7.1417}$$

Therefore:

$$T_n = \frac{\sqrt{\chi_1^2/1}}{\sqrt{\chi_n^2/n}} = \sqrt{\frac{\chi_2^1/1}{\chi_n^2/n}} \tag{5.7.1418}$$

And as we have also seen that:

$$F_{n,m}=\frac{\sqrt{\chi_n^2/n}}{\sqrt{\chi_m^2/m}} \tag{5.7.1419}$$

it follows that:

$$T_n=\sqrt{F_{1,n}} \tag{5.7.1420}$$

or more commonly in practice:

$$\boxed{T_n^2=F_{1,n}} \tag{5.7.1421}$$

We will now use a result proved during our study of the Gamma distribution. We have effectively seen that the sum of two random variables following a Gamma distribution also follows a Gamma distribution where the two parameters are added:

$$X+Y=\gamma(p+q,\lambda) \tag{5.7.1422}$$

As the Chi-square distribution is a special case of the Gamma distribution, the same result applies.

To be more precise, this is equivalent to say: If $X_1,\ldots,X_k$ are random independent and identically distributed (i.i.d.) variables $\mathcal{N}(0,1)$ then by extension of the above proof where we have shown that:

$$\left(X_{\mathcal{N}(0,1)}\right)^2=\chi^2(1) \tag{5.7.1423}$$

and by the property of linearity of the Gamma distribution, then sum of their squares follows a chi-square distribution of degree k such that:

$$\boxed{\chi^2(k)=X_1^2+X_2^2+\ldots+X_k^2} \tag{5.7.1424}$$

Thus, the distribution of χ^2 of k degrees freedom is the probability distribution of the sum of squares of k Normal centered reduced variables linearly independent of each other. It is in fact the linearity property of the chi-square distribution (implicitly the linearity of the Gamma distribution)!

Now see another significant property of the chi-square distribution: If $X_1,\ldots,X_n$ are independent and identically distributed $\mathcal{N}(\mu,\sigma)$ (thus the same mean and the same standard and following a Normal distribution) random variables and if we write the maximum likelihood estimator variance by:

$$\boxed{S_*^2=\frac{1}{n}\sum_{i=1}^{n}(X_i-\mu)^2} \tag{5.7.1425}$$

then, the ratio of the random variable S_*^2 on the standard deviation assumed to be known for the entire population ("the true standard deviation" or "theoretical standard deviation"!) multiplied by the number of individuals n population follows a chi-square distribution of degree n such that:

$$\chi^2(n)=\chi^2_n=\frac{nS^2_*}{\sigma^2} \tag{5.7.1426}$$

This result is named the "Cochran theorem" or "Fisher-Cochran theorem" (in the particular case of Gaussian samples) and thus gives us a distribution for the empirical standard deviations (whose parent law is a Normal distribution!).

Using the value of the standard deviation proved during our study of chi-square distribution we have:

$$\mathrm{V}\left(\frac{nS^2_*}{\sigma^2}\right)=\mathrm{V}(\chi^2(n))=2n \tag{5.7.1427}$$

But n and σ are imposed and are therefore considered as constants. We have therefore:

$$\frac{n^2}{\sigma^4}\mathrm{V}(S^2_*)=\mathrm{V}(\chi^2(n))=2n\Rightarrow \mathrm{V}(S^2_*)=\sigma_{S^2_*}=\sigma^4\frac{2}{n} \tag{5.7.1428}$$

And therefore we have an expression of the standard deviation of the empirical standard deviation if we know the standard deviation of the population:

$$\sigma_{S_*}=\sigma^2\sqrt{\frac{2}{n}} \tag{5.7.1429}$$

But we have proved during our study of estimators that:

$$\hat{\sigma}=\sqrt{\frac{n-1}{n}}\sigma \tag{5.7.1430}$$

It follows:

$$\hat{\sigma}_{S_*}=\sqrt{\frac{n-1}{n}}\sigma_{S^2_*}=\sqrt{\frac{n-1}{n}}\sigma^2\sqrt{\frac{2}{n}}=\sqrt{\frac{2(n-1)}{n^2}}\sigma^2 \tag{5.7.1431}$$

It follows therefore the sometimes important relation in the practice of the estimator of the standard deviation of ... the standard deviation:

$$\boxed{\hat{\sigma}_{S_*}=\sqrt{\frac{2(n-1)}{n^2}}\sigma^2} \tag{5.7.1432}$$

Recall that the parent population is said to be "infinite" if the sample selection with replacement or if the size N of the parent population is much higher than this of the sample of size n.

Remarks

R1. In laboratories the $X_1,\ldots,X_n$ can be seen as a class of individuals of the same product identically studied by different research teams with instruments of the same precision (standard deviation of the measure identically equal).

R2. S^2_* is the "inter-class variance" also named "explained variance". So it gives a measure of the variance occurring in different laboratories.

What is interesting here is that from the calculation of the chi-square distribution and by knowing n and the standard deviation σ^2 it is possible to estimate the interclass variance (and also interclass standard deviation).

To see that this latter property is a generalization of the basic relation:

$$\chi^2(n)=X_1^1+X_2^2+\ldots+X_n^2 \tag{5.7.1433}$$

it suffices to see that the random variable nS_*^2/σ^2 is a sum of n squares of $\mathcal{N}(0,1)$ independent of each other. Indeed, recall that a centered reduced random variable (see our study of the Normal distribution) is given by:

$$Y=\frac{X-\mu}{\sigma} \tag{5.7.1434}$$

Therefore:

$$\frac{nS_*^2}{\sigma^2}=\frac{n}{\sigma^2}\frac{1}{n}\sum_{i=1}^{n}(X_i-\mu)^2=\sum_{i=1}^{n}\left(\frac{X_i-\mu}{\sigma}\right)^2 \tag{5.7.1435}$$

However, since the random variables $X_1,\ldots,X_n$ are independent and identically distributed according to a Normal distribution, then the random variables:

$$\frac{X_1-\mu}{\sigma},\ldots,\frac{X_n-\mu}{\sigma} \tag{5.7.1436}$$

are also independent and identically distributed according to a Normal distribution but a centered reduced one.

Since:

$$\frac{nS_*^2}{\sigma^2}=\chi^2(n) \tag{5.7.1437}$$

rearranging we get:

$$\sigma^2=\frac{nS_*^2}{\chi^2(n)} \tag{5.7.1438}$$

So on the population of measurements, the true standard deviation follows the relation given above. It is therefore feasible to make statistical inference on the standard deviation When the theoretical mean is known (...).

Since the chi-square distributions is not symmetric, the only way to make this inference is to use numerical calculations and then we denote the confidence interval at the level of 95% (for example ...) as follows:

$$\frac{nS_*^2}{\chi^2_{2.5\%}(n)}\leqslant\sigma^2\leqslant\frac{nS_*^2}{\chi^2_{97.5\%}(n)} \tag{5.7.1439}$$

Either by writing $95\% = 1-\alpha$:

$$\boxed{\frac{nS_*^2}{\chi^2_{\alpha/2}(n)} \leqslant \sigma^2 \leqslant \frac{nS_*^2}{\chi^2_{1-\alpha/2}(n)}} \tag{5.7.1440}$$

the denominator being obviously the quantile of the chi-squared distribution. This relation is rarely used in practice as the theoretical average (mean) is not known. In order to avoid confusion, the latter relation is often denoted as follows:

$$\frac{nS_*^2}{\chi^2_{\alpha/2,n}} \leqslant \sigma^2 \leqslant \frac{nS_*^2}{\chi^2_{1-\alpha/2,n}} \tag{5.7.1441}$$

Let's see the most common case:

5.7.9.1.3 C.I. on the Variance with known empirical Mean

Let us now make statistical inference when the theoretical average μ of the population (i.e. the mean) is not known. To do this, consider now the sum of:

$$\chi^2(n)=\sum_{i=1}^n\left(\frac{X_i-\mu}{\sigma}\right)^2=\frac{1}{\sigma^2}\sum_{i=1}^n(X_i-\mu)^2=\frac{1}{\sigma^2}\sum_{i=1}^n\left((X_i-\bar{X})+(\bar{X}-\mu)\right)^2 \tag{5.7.1442}$$

where for recall is $\bar{X}$ the empirical average (arithmetic mean) of the sample:

$$\bar{X}=\frac{1}{n}\sum_{i=1}^n X_i \tag{5.7.1443}$$

Continuing the development we have:

$$\chi^2(n)=\frac{1}{\sigma^2}\left[\sum_{i=1}^n(X_i-\bar{X})^2+2(\bar{X}-\mu)\sum_{i=1}^n(X_i-\bar{X})+n(\bar{X}-\mu)^2\right] \tag{5.7.1444}$$

However, we have proved earlier in this chapter that the sum of the deviations from the mean was zero. So:

$$\begin{aligned}\chi^2(n)&=\frac{1}{\sigma^2}\left[\sum_{i=1}^n(X_i-\bar{X})^2+2(\bar{X}-\mu)\cdot 0+n(\bar{X}-\mu)^2\right]\\&=\frac{1}{\sigma^2}\left[\sum_{i=1}^n(X_i-\bar{X})^2+n(\bar{X}-\mu)^2\right]\\&=\sum_{i=1}^n\frac{(X_i-\bar{X})^2}{\sigma^2}+\frac{n(\bar{X}-\mu)^2}{\sigma^2}=\sum_{i=1}^n\frac{(X_i-\bar{X})^2}{\sigma^2}+\left(\frac{\bar{X}-\mu}{\sigma^2/\sqrt{n}}\right)^2\end{aligned} \tag{5.7.1445}$$

and by taking back the unbiased estimator of the Normal distribution (we change notation to respect the traditions and differentiate the empirical average of the theoretical mean):

$$S^2=\frac{1}{n-1}\sum_{i=1}^n(X_i-\bar{X})^2 \tag{5.7.1446}$$

Thus:

$$\chi^2(n)=\sum_{i=1}^{n}\frac{(X_i-\bar{X})^2}{\sigma^2}+\left(\frac{\bar{X}-\mu}{\sigma^2/\sqrt{n}}\right)^2=\frac{(n-1)S^2}{\sigma^2}+\left(\frac{\bar{X}-\mu}{\sigma^2/\sqrt{n}}\right)^2 \tag{5.7.1447}$$

or with another common notation:

$$\chi^2(n)=\frac{(n-1)S^2}{\sigma^2}+\left(\frac{M_n-\mu}{\sigma^2/\sqrt{n}}\right)^2 \tag{5.7.1448}$$

Since the second term (squared) follows a Normal centered reduced distribution too, then if we remove it we get by the proof made earlier above about the chi-square distribution property, the following result:

$$\chi^2(n-1)=\frac{(n-1)S^2}{\sigma^2} \tag{5.7.1449}$$

These developments allow us this time to also make inferences about the variance of a $\mathcal{N}(0,1)$ distribution when the parameters μ and σ of the parent population are both unknown. It is this result that gives us, for example, the confidence interval:

$$\boxed{\frac{(n-1)S^2}{\chi^2_{\alpha/2}(n-1)}\leqslant\sigma^2\leqslant\frac{(n-1)S^2}{\chi^2_{1-\alpha/2}(n-1)}} \tag{5.7.1450}$$

when the theoretical average (mean) μ is unknown. And also to avoid any confusion, it is more usual to write:

$$\frac{(n-1)S^2}{\chi^2_{\alpha/2,n-1}}\leqslant\sigma^2\leqslant\frac{(n-1)S^2}{\chi^2_{1-\alpha/2,n-1}} \tag{5.7.1451}$$

In the same way as above, we can calculate the standard deviation of the standard deviation that has a great importance in the practice of finance:

$$\begin{aligned}&\text{V}\left(\frac{(n-1)S^2}{\sigma^2}\right)=\text{V}(\chi^2_{n-1}\\&\frac{(n-1)^2}{\sigma^4}\text{V}(S^2)=2(n-1)\\&\text{V}(S^2)=\frac{2\sigma^4}{n-1}\\&\sigma_{S^2}=\sqrt{\frac{2}{n-1}}\sigma^2\end{aligned} \tag{5.7.1452}$$

5.7.9.1.4 C.I. on the Mean with known empirical Variance

We have proved much higher that the Student distribution came from the following relation:

$$T(k)=\frac{Z}{\sqrt{U/k}} \tag{5.7.1453}$$

if Z and U are independent random variables and if Z follows a Normal centered reduced distribution $\mathcal{N}(0,1)$ and U a chi-square distribution $\chi^2(k)$ as:

$$f_T(t)=\frac{\Gamma\left(\dfrac{n+1}{2}\right)}{\Gamma(n/2)\sqrt{k\pi}}\left(1+\frac{t^2}{n}\right)^{-\frac{k+1}{2}} \tag{5.7.1454}$$

and remember that its density function is symmetrical!

Here is a very important application of the above result:

Suppose that $X_1,\ldots,X_n$ is a random sample of size n from a distribution $\mathcal{N}(\mu,\sigma)$. So we can already write that following developments made above:

$$Z=\frac{\bar{X}-\mu}{\sigma/\sqrt{n}} \tag{5.7.1455}$$

And for U that follows a $\chi^2(k)$ distribution, then if we ask that $k=n-1$ then according to the results above:

$$U=\frac{(n-1)S^2}{\sigma^2}=\chi^2(n-1) \tag{5.7.1456}$$

We then get after some trivial simplifications:

$$\frac{Z}{\sqrt{U/k}}=\frac{\dfrac{X-\mu}{\sigma/\sqrt{n}}}{\sqrt{\dfrac{(n-1)S^2}{\sigma^2}/(n-1)}}=\frac{\dfrac{X-\mu}{1/\sqrt{n}}}{\sqrt{\dfrac{(n-1)S^2}{(n-1)}}}=\frac{\dfrac{X-\mu}{1/\sqrt{n}}}{\sqrt{S^2}}=\frac{\bar{X}-\mu}{S/\sqrt{n}} \tag{5.7.1457}$$

So since:

$$T(k)=\frac{Z}{\sqrt{U/k}} \tag{5.7.1458}$$

follows a Student distribution with parameter k then we get the "independent one-sample T-test" or simply named "one-sample T-test":

$$\boxed{\frac{\bar{X}-\mu}{S/\sqrt{n}}=T(n-1)} \tag{5.7.1459}$$

which also follows a Student distribution of parameter $n-1$ and is widely used in laboratories for calibration testing[45].

---

[45] The engineer must not forget that a calibrated instrument, does not mean that is measures correctly! However it means that it has known values of incertitude on its measurements relatively to a reference or a specification!

This gives us also after rearrangement:

$$\mu = \bar{X} - \frac{S}{\sqrt{n}} T(n-1) \tag{5.7.1460}$$

This allows us to make inference about the mean μ of a Normal distribution with the theoretical standard deviation being unknown (meaning that there is not enough experimental values) but where the unbiased estimator of the standard deviation is known. It is this result that gives us the confidence interval[46]:

$$\boxed{\bar{X} - \frac{S}{\sqrt{n}} T_{\alpha/2}(n-1) \leqslant \mu \leqslant \bar{X} + \frac{S}{\sqrt{n}} T_{\alpha/2}(n-1)} \tag{5.7.1461}$$

where we see the same factors as for the statistical inference on the average (mean) of a (theoretical) random with know standard deviation as the Student distribution is asymptotically equal to the Normal distribution for large values of n. Thus, the previous interval and the following interval:

$$\bar{X} - Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \leqslant \mu \leqslant \bar{X} + Z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \tag{5.7.1462}$$

gives very similar values (to three decimal places) for values of n at around $10,000$ (in practice we consider that for 100 this is the same...).

We immediately deduce by the stability property of the chi-square distribution (proved above in that this property arises from the Gamma distribution) the following test that we find in many statistical software:

$$(\bar{X}_2 - \bar{X}_1) - T_{\alpha/2}(n-2)\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}} \leq \mu_2 - \mu_1 \leq (\bar{X}_2 - \bar{X}_1) + T_{\alpha/2}(n-2)\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}} \tag{5.7.1463}$$

named "bilateral t (Student) test on the difference of two means" or more simply "two sample T-test".

We can of course therefore also determine the probability that the mean is inside or outside a certain range ... (the both case being widely used in industry).

The reader can for fun control with Microsoft® Excel® 11.8346 that for a large number of measurements n, the Student distribution tends to the Normal centered reduced distribution by comparing the values of the two functions below:

```
=T.INV(5%/2,n-1)
=NORM.S.INV(5%/2)
```

---

[46] Don't forget that in this textbook we write $T_{\alpha/2}$ where most authors write $T_{1-\alpha/2}$

Remark

The previous result was obtained by William S. Gosset around 11910 (holocene calendar). Gosset who had studied mathematics and chemistry, worked as a statistician for the Guinness brewery in England. At that time, we knew that if $X_1, \ldots, X_n$ are independent and identically distributed random variables then:

$$\frac{\bar{X}-\mu}{\sigma/\sqrt{n}}=\mathcal{N}(0,1) \quad (5.7.1464)$$

However, in statistical applications we were rather obviously interested in the following quantity:

$$\frac{\bar{X}-\mu}{S/\sqrt{n}} \quad (5.7.1465)$$

We then merely assume that this amount followed almost a Normal centered reduced distribution, which was not a bad approximation as can show the image below ($\mathrm{d}f = n-1$):

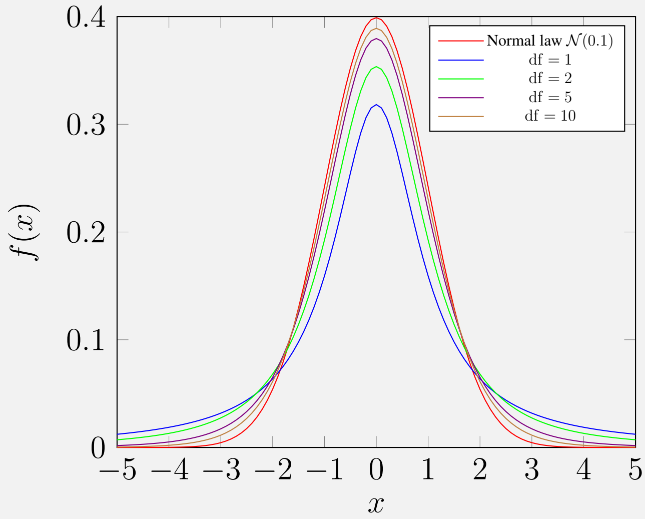

Figure 5.161: **Comparison between the Normal and Student distribution functions**

After numerous simulations, Gosset came to the conclusion that this approximation was valid only when n is large enough (so that gave him the indication that there must be somewhere behind the central limit theorem). He decided to determine the origin of the distribution and after completing a course in statistics with Karl Pearson he obtained his famous result that he published under the pseudonym Student. Thus, is why we name "Student distribution" that law that should have been named the "Gosset distribution".

Finally, note that the Student's T-test is also used to identify whether changes (increasing or vice versa) in the average of two identical populations are statistically significant. That is to say, if the size of two dependent samples is the same then we can develop the following test (we included all different types of writing that can be found in the literature and in many software implementing this test):

$$\begin{aligned}T(n-1)&=\frac{\bar{X}-\mu}{S/\sqrt{n}}=\frac{X_{\bar{D}-\mu_D}}{S_D/\sqrt{n}}=\frac{\bar{D}-\delta_0}{S_D/\sqrt{n}}=\frac{\dfrac{1}{n}\displaystyle\sum_i d_i-\delta_0}{S_D/\sqrt{n}}\\&=\frac{\dfrac{1}{n}\displaystyle\sum_i(X_{i2}-X_{i1})-\delta_0}{S_D/\sqrt{n}}=\frac{\left(\dfrac{1}{n}\displaystyle\sum_i X_{i2}-\dfrac{1}{n}\displaystyle\sum_i X_{i1}\right)-\delta_0}{S_D/\sqrt{n}}=\frac{(\bar{X}_2-\bar{X}_1)-\delta_0}{S_D/\sqrt{n}}\end{aligned}\tag{5.7.1466}$$

With:

$$S_D=\sqrt{\frac{1}{n-1}\sum_i(d_i-\bar{D})}=\sqrt{\mathrm{V}(X_1-X_2)}\tag{5.7.1467}$$

And in the homoscedastic case where $\mathrm{V}(X_1)=\mathrm{V}(X_2)$, remembering that:

$$\begin{aligned}\mathrm{V}(X_1-X_2)&=\mathrm{V}(X_1)+\mathrm{V}(X_2)-2\mathrm{cov}(X_1,X2)=\mathrm{V}(X_1)+\mathrm{V}(X_2)-2\rho\sqrt{\mathrm{V}(X_1)}\sqrt{\mathrm{V}(X_2)}\\&=\sigma^2+\sigma^2-2\rho\sigma\sigma=2\sigma^2(1-\rho)\end{aligned}\tag{5.7.1468}$$

Hence:

$$S_D=\sqrt{\mathrm{V}(X_1-X_2)}=\sqrt{2\sigma^2(1-\rho)}\tag{5.7.1469}$$

The relation:

$$T(n-1)=\frac{(\bar{X}_2-\bar{X}_1)-\delta_0}{S_D/\sqrt{n}}\tag{5.7.1470}$$

is very useful for comparing the same sample twice in different measurement situations (sales before or after a discount on an article for example). This relation is named "T-test (Student) averages two paired samples (or dependent samples)" or more simply "paired sample T-test".

Definition (#5.7.136): We speak of "paired samples" if the sample values are taken 2 times on the same individuals (i.e. the values of the pairs are not independent, unlike two samples taken independently).

Remark

For paired tests the distribution of each sample is completely unimportant! What matters is the distribution of the "pair differences"!!

5.7.9.1.5 C.I. on the Geometric Mean (for known or unknown Variance)

Let's just see how to compute the confidence interval for the geometric mean that is of main importance in finance! Consider we have $X_1, \ldots X_n$ from some distribution with mean μ and variance σ^2.

Consider $Y_i = \ln(X_i)$ (in practice some people take the $\log$ rather than the $\ln$), where the arithmetic mean of Y is μ_y and it corresponding variance is σ_y^2. Consider the average of the Ys: $\bar{Y}_n = \sum_{i=1}^n Y_i/n$. Then due to the central limit theorem:

$$\sqrt{n}\left(\bar{Y}_n - \mu_y\right) \xrightarrow{d} \mathcal{N}\left(0, \sigma_y^2\right) \tag{5.7.1471}$$

Now consider $e^{\bar{Y}_n}$:

$$\begin{aligned} e^{\bar{Y}_n} &= \exp\left\{\sum_{i=1}^n \frac{1}{n} Y_i\right\} = \exp\left\{\sum_{i=1}^n \frac{1}{n}\ln(X_i)\right\} = \exp\left\{\sum_{i=1}^n \ln(X_i^{1/n})\right\} \\ &= \prod_{i=1}^n \exp\left\{\ln(X_i^{1/n})\right\} = \prod_{i=1}^n X_i^{1/n} = \sqrt[n]{\prod_{i=1}^n X_i} \end{aligned} \tag{5.7.1472}$$

Thus, $e^{\bar{Y}}$ is the geometric mean of the X_i! So next, we can apply the Delta method to the central limit theorem. Define $g(x) = e^x$, then $g'(x) = e^x$. By the Delta method (see section Theoretical Computing page 6504):

$$\sqrt{n}\left(e^{\bar{Y}_n} - e^{\mu_y}\right) \xrightarrow{d} \mathcal{N}\left(0, e^{2\mu_y}\sigma_y^2\right) \tag{5.7.1473}$$

Notice well the $e^{2\mu_y}$ in front of the σ_y^2! So we you have a tool to make our confidence intervals from!

e^{μ_y} is our true geometric mean of the Ys, and we need to make a confidence interval for this (this is not a confidence interval for the expected value μ). The first step is to estimate σ_y^2. Since σ_y^2 is the variance of the Ys:

$$\sigma_y^2 := \frac{1}{n}\sum_{i=1}^n \left(Y_i - \bar{Y}_n\right)^2 = \frac{1}{n}\sum_{i=1}^n \left(\ln(X_i) - \ln(e^{\bar{Y}_n})\right)^2 = \frac{1}{n}\sum_{i=1}^n \ln\left(\frac{X_i}{e^{\bar{Y}_n}}\right) \tag{5.7.1474}$$

To make our $100(1-\alpha)\%$ confidence interval for the true geometric mean of the Xs we then have:

$$e^{\bar{Y}_n} - Z_{\alpha/2}\frac{e^{\bar{Y}_n}\sigma_y}{\sqrt{n}} \leq G_X \leq e^{\bar{Y}_n} + Z_{\alpha/2}\frac{e^{\bar{Y}_n}\sigma_y}{\sqrt{n}} \tag{5.7.1475}$$

That can also be written:

$$\boxed{\hat{G}_X - Z_{\alpha/2}\frac{e^{\bar{Y}_n}\sigma_y}{\sqrt{n}} \leq G_X \leq \hat{G}_X + Z_{\alpha/2}\frac{e^{\bar{Y}_n}\sigma_y}{\sqrt{n}}} \tag{5.7.1476}$$

This is the "Z-test of the geometric mean" (when the variance is known).

Keep in mind that the Z-test of the geometric mean must be used only if the σ_y is known. Otherwise we should use the Student version of that test! That is:

$$\boxed{\hat{G}_X - T_{\alpha/2}(n-1)\frac{e^{\bar{Y}_n}\hat{\sigma}_y}{\sqrt{n}} \leq G_X \leq \hat{G}_X + T_{\alpha/2}(n-1)\frac{e^{\bar{Y}_n}\hat{\sigma}_y}{\sqrt{n}}} \tag{5.7.1477}$$

This is the "T-test of the geometric mean".

> Caution! Many people and statistical softwares calculate this interval the wrong way. For example in the Stata documentation in 12021 (holocene calendar), the method of calculation is explicitly described as: "*To compute the geometric mean, the function* `ameans` *creates* $u_j = \ln(x_j)$ *for all positive* x_j. *The arithmetic mean of the* u_j *and its confidence interval are then computed as in the function* `ci`. *Let* $\bar{u}$ *be the resulting mean, and let* $[L, U]$ *be the corresponding confidence interval. The geometric mean is then* $\exp(\bar{u})$, *and its confidence interval is* $[\exp(L), \exp(U)]$.". And sadly the package DescTools of the `R` statistical software and its function Gmeans() is based on Stata method...

5.7.9.1.6 Binomial exact Test

Often when measuring we want to compare two small samples taken randomly (without replacement!) from also a small population ... to know if they are statistically significantly different or not as when we were expecting a perfect equality!

We are looking for a suitable test for the following cases:

- To know if the sample of a population prefers to use a given technical method of work rather than another when we expect that the population does not prefer one of the other
- To know if the sample of a population has a predominant characteristic among two possibilities when we expect that the population is well balanced

Before going further into details, let us remind that we must be extremely cautious about how to get the two samples. The experience must be unbiased, this is to say for reminder, that the sampling protocol must not favour one of the both characteristics of the population (if you study the balance between man/woman in a population by attracting people for the survey with a gift in the form of jewellery or just by calling during the workdays you will have a biased sample ... because you'll probably naturally have more women than men...).

This said, this situation match with a binomial distribution for which we proved earlier in this chapter that the probability of k successes in a population of size N with a probability of success is p (probability of failure q being therefore $1-p$) was given by the relation:

$$P(N,k) = C_k^N p^k q^{N-k} = C_k^N p^k (1-p)^{N-k} \tag{5.7.1478}$$

In the case before we are interesting we have $p = q = 0.5$:

$$P(N,k) = C_k^N 0.5^k 0.5^k = 0.5^N C_k^N \tag{5.7.1479}$$

while remembering that the distribution will not be symmetrical and especially if the population size N is small.

If we now denote by x the number of successes (considered as the size of the first sample) and y is the number of failures (considered as the size of the second sample), then we have:

$$P(N,k)=0.5^N C_k^N = P(x+y,k)=0.5^{x+y}C_k^{x+y} \tag{5.7.1480}$$

This being done, to build the test and by the asymmetry of the distribution, we will calculate the cumulative probability that k is smaller than the x obtained by the experience and sum it to the cumulative probability that k is greater than the y obtained by the experiment (which corresponds to a cumulative probability of respectively left and right tails of the distribution). So this sum corresponds to the probability:

$$P=0.5^N\sum_{k=0}^{x} C_k^N + 0.5^N \sum_{k=y}^{N} C_k^N \tag{5.7.1481}$$

and this last relation is named "binomial exact test (two-tailed)".

If the probability P obtained by the sum is above a certain cumulative probability fixed in advance, then we say that the difference with a random sample in a perfectly balanced population is not statistically significant (bilaterally ...) and respectively if it is below, the difference will be statistically significant and therefore we reject the assumed equilibrium.

Therefore, if:

$$0.5^N\sum_{k=0}^{x'} C_k^N + 0.5^N \sum_{k=y'}^{N} C_k^N = 0.5^N\left(\sum_{k=0}^{x'} C_k^N + \sum_{k=y'}^{N} C_k^N\right) \geq \alpha \tag{5.7.1482}$$

the difference with a balanced population will be considered not statistically significant. Often we will α to be at the maximum equal to 5% (but rarely below) which corresponds to a confidence interval of 95%.

Unfortunately from a statistical software to the other the required parameters or results will not necessarily be the same (spreadsheets softwares for example do not include a specific function for the binomial test, will often have to build a table or develop yourself a function). For example, some softwares automatically calculate and impose (which is quite logical in a sense...)

$$0.5^N\left(\sum_{k=0}^{x-1} C_k^N + \sum_{k=y+1}^{N} C_k^N\right) = P \tag{5.7.1483}$$

✍**Example:**

From a small population having two particular characteristics x and y that interest us and which we expect to have a perfect balance but as $x=y$ we actually got $x=5$ and $y=7$. We would like do the calculation with Microsoft® Excel® 11.8346 to know whether this difference is statistically significant or not at a level of 5%?

So, to answer this question, we will calculate the cumulative probability:

$$0.5^N\left(\sum_{k=0} C_k^N+\sum_{k=y}^{N} C_k^N\right)=0.5^{12}\left(\sum_{k=0}^{5} C_k^{12}+\sum_{k=7}^{12} C_k^{12}\right) \tag{5.7.1484}$$

which gives us:

	A	B
1	*k*	Binomial Coeff.
2	0	1
3	1	12
4	2	66
5	3	220
6	4	495
7	5	792
8	7	792
9	8	495
10	9	220
11	10	66
12	11	12
13	12	1
14	*P*	0.774

Figure 5.162: **Calculated values of the binomial coefficients in Microsoft® Excel® 11.8346**

thus explicitly:

	A	B
1	*k*	Binomial Coeff.
2	0	=COMBIN(12,A2)
3	1	=COMBIN(12,A3)
4	2	=COMBIN(12,A4)
5	3	=COMBIN(12,A5)
6	4	=COMBIN(12,A6)
7	5	=COMBIN(12,A7)
8	7	=COMBIN(12,A8)
9	8	=COMBIN(12,A9)
10	9	=COMBIN(12,A10)
11	10	=COMBIN(12,A11)
12	11	=COMBIN(12,A12)
13	12	=COMBIN(12,A13)
14	*P*	=0.5^12*SUM(B2:B13)

Figure 5.163: **Formulas for calculating binomial coefficients in Microsoft® Excel® 11.8346**

thus the cumulative probability being 0.774 (i.e. 77.4%) the difference compared with balanced population will be considered as not statistically significant.

Remark

This test is also used by most statistical software (such as Minitab) to give a confidence interval of the conformity of opinions in relation to that of an expert. This is what we call a R&R study (reproducibility & repeatability) by attributes (see the companion Minitab for an example).

5.7.9.1.7 C.I. for a Proportion

For information some statisticians use the fact that the Normal distribution arises from the Poisson distribution which itself derives from the binomial distribution (we have proved it when n tends to infinity and p and q are of the same order) to build a confidence interval in the context of the analysis of proportions (widely used in the analysis of the quality in the industry).

To see this, we note X_i the random variable defined by:

$$X_i = \begin{cases} 1 & \text{if the } i\text{th element of the sample has the attribute } A \\ 0 & \text{otherwise} \end{cases} \tag{5.7.1485}$$

where the attribute A can be the property "defective" or "non-defective" for example, in an analysis of pieces. We note by k the number of successes of the attribute A.

The random variable $X = X_1 + X_2 + \ldots + X_n$ we have proved it earlier in this chapter, follows a binomial distribution with parameters n and p with the moments:

$$\begin{aligned} \mu &= \mathrm{E}(X) = np \\ \sigma &= \sqrt{\mathrm{V}(X)} = \sqrt{npq} = \sqrt{np(1-p)} \end{aligned} \tag{5.7.1486}$$

That said, we do not know the true value of p. We will use the estimator of the binomial distribution proved above:

$$\hat{p} = \frac{k}{n} = \frac{X}{n} \tag{5.7.1487}$$

Based on the properties of the mean we have then:

$$\mathrm{E}(\hat{p}) = \mu_{\hat{p}} = \mathrm{E}\left(\frac{X}{n}\right) = \frac{np}{n} = p \tag{5.7.1488}$$

And by using the properties of the variance, we have the following relation for the variance of the sample mean of the proportion:

$$\mathrm{V}(\hat{p}) = \sigma_{\hat{p}}^2 = \mathrm{V}\left(\frac{X}{n}\right) = \frac{\mathrm{V}(X)}{n^2} = \frac{np(1-p)}{n^2} = \frac{p(1-p)}{n} \tag{5.7.1489}$$

This then brings us to:

$$\mu_{\hat{p}} \cong \hat{p} \quad \text{and} \quad \sigma_{\hat{p}} \cong \sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \tag{5.7.1490}$$

Finally, remember that we have proved that the Normal distribution resulted from the binomial distribution under certain conditions (practitioners admit that it is applicable as $n > 50$ and $np \geq 5$). In other words, the random variable X following a binomial distribution follows a Normal distribution under certain conditions. Obviously, if X follows a Normal distribution then X/n also (and so do $\hat{p}$...). Therefore we can center and reduce $\hat{p}$ so that it behaves as the reduced Normal centered random variable denoted by Z:

$$Z=\frac{\hat{p}-p}{\sqrt{\dfrac{\bar{p}(1-\bar{p})}{n}}} \tag{5.7.1491}$$

✍**Examples:**

E1. If 5% of the annual production of a business fails, what is the probability that by taking a sample of 75 pieces of the production line only 2% or less will be defective?

We therefore have:

$$Z=\frac{0.02-0.05}{\sqrt{\dfrac{0.05\cdot 0.95}{75}}} \tag{5.7.1492}$$

The corresponding cumulative probability to that value can be easily obtained with Microsoft® Excel® 11.8346:

`=NORMSDIST(-1.19)=11.66%`

But note that we do not have $np\geq 5$ that is satisfied therefore we could exclude to use this result.

E2. In its report from 11998 (holocene calendar), JP Morgan explained that during the year 11998 (holocene calendar) its losses went beyond the Value at Risk (see section Economy page 7858) 20 days on 252 working days of the year based on a 95% temporal VaR (thus 5% of working days considered as loss). At the threshold of 95% it is just bad luck or is that the VaR model used was bad?

$$Z=\frac{\hat{p}-p}{\sqrt{\dfrac{\bar{p}(1-\bar{p})}{n}}}=\frac{n\hat{p}-np}{\sqrt{\hat{p}(1-\hat{p})n}}=\frac{-0.05\cdot 252-20}{\sqrt{0.05(1-0.05)252}}\cong -2.14<-1.96 \tag{5.7.1493}$$

So it was just bad luck.

E3. Some individuals expect all people declared clinically death to experience NDE (Near Death Experience). The study *Near-death experience in survivors of cardiac arrest: a prospective study in the Netherlands* on a sample of 344 patients has 62 patients (18%) that reported a NDE (i.e. 82% did not experience NDE). We want to know if 82% is statistically significantly different of the expected 100% at a threshold of 5%:

$$Z=\frac{n\hat{p}-np}{\sqrt{\hat{p}(1-\hat{p})n}}=\frac{244-344}{\sqrt{0.05(1-0.05)344}}\cong -24.73<-1.96 \tag{5.7.1494}$$

The corresponding cumulative probability to that value can be easily obtained with Microsoft® Excel® 11.8346:

`=NORMSDIST(-24.73)=100%`

Therefore NDE is not a global phenomenon and we can not assign to it, beyond all reasonable doubt, an absolute existence! However other factors may explain the fact that only a few people experience NDE.

We can now approximate the confidence interval for the proportion by using the fact that the binomial distribution has a Normal asymptotic behaviour under the conditions demonstrated during our introduction of the Normal distribution such as we get the "one-proportion Z test" or also more commonly named "one-proportion p test":

$$\boxed{\hat{p} - Z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \leq p \leq \hat{p} + Z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}} \tag{5.7.1495}$$

That (non-parametric) test is also commonly named "binomial test" and must not be confused with the binomial exact test derived at page 869.

Before proceeding to an example, it may be useful to clarify to the reader that this approximation by a Normal distribution is very common and that we'll meet it again numerous times in proofs that will follow. It is even so common that this approximation method has a name..: the "Wald's method" (well actually there are several Wald methods but we will only use the most known one).

Example:

We take $\alpha=5\%$, then we have:

$$\boxed{\hat{p}-Z_{0.025}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}\leq p\leq\hat{p}+Z_{0.025}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}} \tag{5.7.1496}$$

That is to say:

$$\hat{p}-1.96\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}\leq p\leq\hat{p}+1.96\sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \tag{5.7.1497}$$

On a production of 300 elements we found that 8 of them were defect. What is the confidence interval?

We check first with:

$$\hat{p}=\frac{8}{300}\cong 2.66\% \tag{5.7.1498}$$

that:

$$n\hat{p}=300\cdot\frac{8}{300}=8\geq 5 \tag{5.7.1499}$$

So it is acceptable to use the confidence interval by the Normal distribution. We therefore have:

$$\frac{8}{300}-1.96\sqrt{\frac{\frac{8}{300}\left(1-\frac{8}{300}\right)}{300}}\leq p\leq\frac{8}{300}+1.96\sqrt{\frac{\frac{8}{300}\left(1-\frac{8}{300}\right)}{300}} \tag{5.7.1500}$$

That is to say:

$$0.84\%\leq p\leq 4.49\% \tag{5.7.1501}$$

Caution! Because the comparison of two proportions is of main interest for the pharmaceutical industry, it is therefore a quite intensive mathematical research topic. At the point that the Wald confidence interval for the comparison of two proportions is not the only existing one. Some statistical softwares for (like R for example) give the options to use complementary (more robust or exact) confidence intervals like: the Wilson confidence interval, the Agresti-Coull confidence interval, the Agresti-Caffo confidence interval, the Newcombe confidence interval, the Miettinen-Nurminen confidence interval, the Skewness-corrected asymptotic score (SCAS) confidence interval, the Blaker confidence interval, the Clopper-Pearson confidence interval, the Hepworth confidence interval. As always... never forget the Dunning-Kruger effect... especially in Science!

To conclude this subject, we can obviously be interested to the number of individuals (sample size) necessary to satisfy a certain (imposed) confidence interval accuracy when having an imposed standard deviation.

We therefore have according to the above assumptions and in the acceptance of the approximation by a Normal distribution:

$$Z=\frac{\hat{p}-p}{\sqrt{\dfrac{pq}{n}}}=\frac{\delta}{\sqrt{\dfrac{p(1-p)}{n}}} \tag{5.7.1502}$$

And by proceeding in an identical manner to the developments made above with the Normal distribution, we get the "sample size for proportion estimation by binomial distribution":

$$\boxed{n_p\cong\frac{Z_{\alpha/2}^2p(1-p)}{\delta^2}=\frac{Z_{\alpha/2}^2pq}{\delta^2}} \tag{5.7.1503}$$

obviously we normally take the integer value in practice...

Applying the same reasoning for two groups of proportions we get the "sample size for two proportions estimation by binomial distribution":

$$n_{2p}\cong\frac{Z_{\alpha/2}^2[p_1(1-p_1)+p_2(1-p_2)]}{\delta^2} \tag{5.7.1504}$$

A question that often comes up in practice is the fact to know whether you have to take a unilateral or bilateral test. In fact there is no precise answer, it depends on what we want to highlight.

Remark

The size of the parent population for the relations developed above does not come into consideration in the calculation of confidence intervals or in one of the sample size, and because it is considered infinite. So be careful to not have sometimes sample sizes that are larger than the possible real parent population... Otherwise you should insert the fpc (finite population factor).

The reader can find in most marketing textbooks tabulated values (including the fpc!) in the result above that lead to the construction of the following table:

	Confidence level $=95\%$			**Confidence level** $=99\%$		
	Margin of error			**Margin of error**		
Population size	5%	2.5%	1%	5%	2.5%	1%
100	80	94	99	87	96	99
500	217	377	475	285	421	485
1,000	278	606	906	399	727	943
10,000	370	1,332	4,899	622	2,098	6,239
100,000	383	1,513	8,762	659	2,585	14,227
500,000	384	1,532	9,423	663	2,640	16,055
1,000,000	384	1,534	9,512	663	2,647	16,317

Table 5.47: **One question survey sample size with fpc factor**

✍**Example:**

We would like to know the number of individuals (sample size) to take in a production lot knowing that the proportion of defective units is imposed at 30% with a tolerated error of about 5% between the actual and empirical proportion and to obtain a confidence interval at a level of 95% of the result:

$$n \cong \frac{Z_{5\%/2}^2 \cdot 30\% \cdot (1-30\%)}{5\%^2} = \frac{(-1.96)^2 \cdot 30\% \cdot 70\%}{5\%^2} \cong 322 \tag{5.7.1505}$$

Remark

The last relation is very often used in sampling theory (analysis for referendum with responses of type: Yes/No) where sometimes the sample size n is imposed for costs reasons of the survey and for which we seek to calculate the uncertainty δ and sometimes the reciprocal (the uncertainty is imposed and therefore we seek to know the sample size).

5.7.9.1.7.1 Variance stabilizing transformation

Often, the variance of an estimator depends on the value of the parameter being estimated. For example, if $X_n \sim$ Binomial (n, p), then with $\hat{p}_n = X_n/n$:

$$\mathrm{V}\left[\widehat{p}_n\right] = \frac{p(1-p)}{n} \tag{5.7.1506}$$

In regression situations, for instance, one usually desires the dependent Y_i' s to have the same variance for each i, so that if these Y_i' s are binomial, or Poisson, the variance will not be constant. However, taking a function of the variables may achieve approximately equal variances. Such a function is named a "variance stabilizing transformation". Formally, if $\widehat{\theta}_n$ is an estimator of θ, then we wish to find a g such that:

$$\sqrt{n}\left(g\left(\widehat{\theta}_n\right) - g(\theta)\right) \xrightarrow{d} \mathcal{N}(0,1) \tag{5.7.1507}$$

The "1" for the variance is arbitrary. The important thing is that it does not depend on θ. In the binomial example, the variance stabilizing g would satisfy:

$$\sqrt{n}\left(g\left(\hat{p}_n\right) - g(p)\right) \xrightarrow{d} \mathcal{N}(0,1) \tag{5.7.1508}$$

We know that:

$$\sqrt{n}\left(\widehat{p}_n - p\right) \xrightarrow{d} \mathcal{N}(0, p(1-p)) \tag{5.7.1509}$$

and by the univariate Δ-method (see section Theoretical Computing page 6504):

$$\sqrt{n}\left(g\left(\hat{p}_n\right) - g(p)\right) \xrightarrow{d} \mathcal{N}\left(0, g'(p)^2 p(1-p)\right) \tag{5.7.1510}$$

What should g be so that the variance is equal to 1? We need to solve to answer that question:

$$g'(p) = \frac{1}{\sqrt{p(1-p)}} \tag{5.7.1511}$$

so that:

$$g(p) = \int_0^p \frac{1}{\sqrt{y(1-y)}}\mathrm{d}y \tag{5.7.1512}$$

First, let $u = \sqrt{y}$, so that $y = u^2$ and $\mathrm{d}y = 2u\mathrm{d}u$, and:

$$g(p) = \int_0^{\sqrt{p}} \frac{1}{u\sqrt{1-u^2}} 2u\mathrm{d}u = 2\int_0^{\sqrt{p}} \frac{1}{\sqrt{1-u^2}}\mathrm{d}u \tag{5.7.1513}$$

The integral is $\arcsin(u)$ (see section Differential and Integral Calculus page 1534), which means the variance stabilizing transformation is:

$$g(p) = 2\arcsin(\sqrt{p}) \tag{5.7.1514}$$

Note that adding a constant to g won't change the derivative. The approximation suggested by:

$$\sqrt{n}\left(g\left(\hat{p}_n\right) - g(p)\right) \longrightarrow^{\mathcal{D}} \mathcal{N}(0,1) \tag{5.7.1515}$$

is then after rearranging the previous relation:

$$2\arcsin\left(\sqrt{\hat{p}_n}\right) \cong \mathcal{N}\left(2\arcsin(\sqrt{p}), \frac{1}{n}\right) \qquad (5.7.1516)$$

An approximate 95% confidence interval for $2\arcsin(\sqrt{p})$ is:

$$2\arcsin\left(\sqrt{\widehat{p}_n}\right) \pm \frac{1}{\sqrt{n}} \qquad (5.7.1517)$$

That interval can be inverted to obtain the interval for p, that is, apply $g^{-1}(u)=\sin(u/2)^2$ to both ends:

$$p \in \left(\sin\left(\arcsin\left(\sqrt{\hat{p}_n}\right)-\frac{1}{\sqrt{n}}\right)^2, \sin\left(\arcsin\left(\sqrt{\hat{p}_n}\right)+\frac{1}{\sqrt{n}}\right)^2\right) \qquad (5.7.1518)$$

This interval may be slightly better than the usual approximate interval:

$$\widehat{p}_n \pm 2\sqrt{\frac{\widehat{p}_n\left(1-\hat{p}_n\right)}{n}} \qquad (5.7.1519)$$

5.7.9.1.7.2 Test of equality (or difference) of two Proportions

Always in the same context as the previous approximation of the binomial distribution by a Normal distribution, the industry (especially biostatistics) likes to compare two proportions of two different populations to see if they are statistically equal or not (i.e. said statistically significantly different or not).

Therefore, let us recall that we have proved the stability of the Normal distribution if two random variables are independent and identically distributed (according to a Normal distribution!):

$$X-Y=\mathcal{N}\left(\mu=\mu_X-\mu_Y,\sigma=\sqrt{\sigma_X^2+\sigma_Y^2}\right) \tag{5.7.1520}$$

Under the above assumptions it is then approximately the same for the difference of two proportions:

$$\begin{aligned}\frac{X}{n_1}-\frac{Y}{n_2}&\cong\mathcal{N}\left(\mu_{\bar{p}_X}-\mu_{\bar{p}_Y},\sqrt{\sigma_{\bar{p}_X}^2+\sigma_{\bar{p}_Y}^2}\right)\cong\mathcal{N}\left(\hat{p}_X-\hat{p}_Y,\sqrt{\sigma_{\hat{p}_X}^2+\sigma_{\hat{p}_Y}^2}\right)\\&=\mathcal{N}\left(\hat{p}_X-\hat{p}_Y,\sqrt{\frac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\frac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}\right)\end{aligned} \tag{5.7.1521}$$

Therefore we know that this new reduced centered variable follows a Normal distribution as:

$$Z=\frac{(\hat{p}_X-\hat{p}_Y)-\mu}{\sqrt{\dfrac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\dfrac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}} \tag{5.7.1522}$$

and as we seek to know the cumulative probability that the mean of the difference is zero, the latter relation is reduced in this case to "Z-test for the equality of two proportions unpooled":

$$Z=\frac{\hat{p}_X-\hat{p}_Y}{\sqrt{\dfrac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\dfrac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}} \tag{5.7.1523}$$

Obviously we can build (as always...) a confidence interval:

$$\boxed{(\hat{p}_X-\hat{p}_Y)-Z_{\alpha/2}\sqrt{\frac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\frac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}\leq p_X-p_Y\leq(\hat{p}_X-\hat{p}_Y)+Z_{\alpha/2}\sqrt{\frac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\frac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}} \tag{5.7.1524}$$

We refer to this interval as the "Wald interval". Wald intervals for a single proportion or for the difference of two proportions are known to perform poorly, and are usually well below the nominal coverage), although they are still widely used in practice because of their simplicity. The Wald interval also suffers from overshoot,that is, bounds of the calculated interval can be outside the range of possible values!

The above test in the field of sensitivity analysis (especially when applied to the design of websites), is sadly named because of a lack of precision the "proportions A/B test" (not to be confuse with the other kind of A/B tests that we will see further below). Indeed we will see later that a confusion can arise because a pooled version of that test also exist, but also an unpooled χ^2 version and pooled χ^2 version...

Warning! The test of the difference of two proportions of two different samples is obviously not the same as the test of the difference of two proportions in the same sample (covariance oblige since the two proportions are therefore no longer independent)! In the latter case we use McNemar's test (see section Numerical Methods page 1264).

However, it seems that the following approximate relation, named "Z-test for the equality of two proportions pooled", following the return on experience is more correct when taking a modified denominator:

$$Z=\dfrac{\hat{p}_X-\hat{p}_Y}{\sqrt{\dfrac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\dfrac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}}=\dfrac{\hat{p}_X-\hat{p}_Y}{\sqrt{\hat{p}(1-\hat{p})\left(\dfrac{1}{n_1}+\dfrac{1}{n_2}\right)}} \qquad (5.7.1525)$$

where $\hat{p}$ will be taken as the mixture of the two populations. That is to say:

$$\hat{p}=\dfrac{\text{sum of events in each of the two samples}}{\text{sum of samples sizes}} \qquad (5.7.1526)$$

thus (by changing the notations of the indices of the experimental proportions):

$$\hat{p}=\dfrac{n_1\hat{p}_1+n_2\hat{p}_2}{n_1+n_2} \qquad (5.7.1527)$$

This test is named "two proportions Z test" or more simply "two proportions p test". In medicine, it is named the "test of differences in risk" (meaning implicitly that each proportion is a segment of the studied population in relation to an undesired event).

Remark

Numerical simulations seems to show that the unpooled variance is slightly more biased than the pooled one. We will also see during our study of the χ^2 test of independance (see page 1238) why softwares like `R` use the χ^2 test instead of the Z-test to compare two proportions.

✍**Example:**

In the context of a sampling plans (see section Industrial Engineering page 8904) we have taken on a first batch of 50 individuals, 48 that are in perfect conditions. In a second batch of 30 individuals, 26 were in perfect condition.

Thus we have:

$$\hat{p}_X=\frac{48}{50}=96\%,\hat{p}_Y=\frac{26}{30}=86.66\% \tag{5.7.1528}$$

We would like to know if the difference is statistically significant with a 95% confidence interval or simply due to chance. We then use:

$$\hat{p}=\frac{n_1\hat{p}_1+n_2\hat{p}_2}{n_1+n_2}=\frac{48+26}{50+30}=92.50\% \tag{5.7.1529}$$

and:

$$Z=\frac{\hat{p}_X-\hat{p}_Y}{\sqrt{\hat{p}(1-\hat{p})\left(\dfrac{1}{n_1}+\dfrac{1}{n_2}\right)}}=\frac{0.96-0.8666}{\sqrt{0.925(1-0.925)\left(\dfrac{1}{50}+\dfrac{1}{30}\right)}}\cong 1.535 \tag{5.7.1530}$$

This corresponds to a cumulative probability using Microsoft® Excel® 11.8346:

```
=NORMSDIST(1.535)=93.77%
```

Therefore the difference is due to chance (that said it is almost in extremis...). In other words, it is not statistically significant under the set constraints.

5.7.9.1.8 Sign Test

We measure something on a sample and later, we measure the same thing on this same sample but with a different method (so it is therefore paired samples!). Both ordered rankings of measures are compared and too each case is assigned a sign ("$+$" for an increase in the rankings, "$-$" in case of descent). Those who remain at the same level are eliminated.

According to the hypothesis to be tested, there are so many "$+$" as "$-$", that is to say, the median of the distribution has not changed (this statement may not seem obvious at first reading so be aware to take time to think about it).

The idea is that for each pair of values, there are only two possible signs of change, we have a chance on two (50% probability) that the difference is positive or negative. This test is based only on the study of signs of the differences between the pairs of individuals, regardless of the values o these differences.

We can wish to control two assumptions:

- The inequality of proportions of signs must be statistically significant. So one of the two signs must be in a small number compared to the other, which corresponds to a left-sided test (the cumulative probability of the small number of characters must be below a certain level α).
- The proportion of the two signs must be low unbalanced $(P(+) = P(-) = 0.5)$. It is therefore in this case a bilateral test (the most common case) with a given level α.

To create such a test, we consider the appearance of the "$+$" and "$-$" as a binary random sampling system where the order of success is not taken into account (it is therefore based on a binomial or hypergeometric distribution) and with replacement (which immediately eliminates the hypergeometric distribution that is not symmetric and problematic to use in practice...). To consider a random sampling with replacement (with the fact that we do not reinject each individual in reality), it is necessary that the population N is large. This is why the sign test considers that the paired values should be continuous (which allows verbatim to approach the hypergeometric distribution by the binomial distribution). However, some statistical software use the hypergeometric distribution for the sake of precision.

Remark

You should know that most statistical software, do implicitly the assumption in this test that the data are continuous and use therefore the binomial distribution.

✍**Example:**

Consider two sets of measurements with two different methods. We would like to test the hypothesis with a confidence level α of 5% if the difference between the two methods is statistically significant (thus we expect a balance of signs). This is therefore two samples sign test (knowing that it is also possible to do the same by comparing the values of a single sample to its median):

$$\begin{gathered}20.4, 25.4, 25.6, 25.6, 26.6, 28.6, 28.7, 29, 29.8, 30.5, 30.9, 31.1\\20.7, 26.3, 26.8, 28.1, 26.2, 27.3, 29.5, 32, 30.9, 32.3, 32.3, 31.7\end{gathered} \tag{5.7.1531}$$

Therefore we have the differences:

$$-0.3, -0.9, -1.2, -2.5, 0.4, 1.3, -0.8, -3.0, -1.1, -1.8, -1.4, -0.6 \tag{5.7.1532}$$

With the signs:

$$-, -, -, -, +, +, -, -, -, -, -, - \tag{5.7.1533}$$

Well it is already clear that the result will be the rejection of the hypothesis as there is no difference. But we will still do the calculations. As the test is a two-sided at the level of 5% , the cumulative probability of obtaining at least two signs "+" must not be less than 2.5% and not more than 97.5% if we want to accept (not reject) the assumption as that the difference is not statistically significant.

We then have:

$$P(X \leq 2) = \sum_{k=0}^{2} C_k^{12} 0.5^k (1-0.5)^{12-k} = \sum_{k=0}^{2} C_k^{12} 0.5^k 0.5^{12-k} = 0.5^{12} \sum_{k=0}^{2} C_k^{12} \cong 1.93\% \tag{5.7.1534}$$

Either with Microsoft® Excel® 14.0.6123:

`=BINOMDIST(2,12,0.5,1)=1.928%`

or if we don't do the approximation by being more accurate with the hypergeometric distribution:

`=HYPGEOM.DIST(2,24/2,12,24,TRUE)=0.17%`

which is not really better...!

So the cumulative probability is less than 2.5% and is by far not more than 97.5%, therefore we reject the hypothesis as that the difference is not statistically significant.

We could accept the hypothesis if we take for α the value:

$$p - \text{value} \cong 1.93\% \cdot 2 = 3.86\% \tag{5.7.1535}$$

but this is not the case!

To conclude on this sign test (median test), we have for information some statistical softwares that propose a confidence interval of the median based on the calculation method described previously (confidence interval of the binomial distribution). However, we think that it would better to use bootstrapping techniques as we have seen in the section on Numerical Methods (page 6740), so won't introduce this technique here. In addition it may be useful to know that some make an approximation using the Normal distribution (as with most tests but we won't study this approximation in this context).

5.7.9.1.9 Mood's Median Test

Here we will introduce a test that has many names: "median test", "Mood's median test" or "Westenberg-Mood's median test" or "Brown-Mood's median test" ...

We consider two independent samples $(X_1,\ldots,X_{n_1})$ and $(Y_1,\ldots,Y_{n_2})$. We assume that $(X_1,\ldots,X_{n1})$ is an independent and identically distributed sample from a continuous distribution F and $(Y_1,\ldots,Y_{n_2})$ is an independent and identically distributed sample from a continuous distribution G.

After the grouping of the n_1+n_2 values of the two samples, $k=n_1M_n$ is the number of observations X_i of the first sample that are greater than the median $N=n_1+n_2$ of the observations (the notation is not great because it can give the impression that it is a multiplication...).

Under the null hypothesis that X and Y variables follow the same continuous distribution (that is to say, $G=F$) hypothesis, the variable $k=n_1M_n$ can take the values $0,1,\ldots,n_1$ according to the hypergeometric distribution:

$$P(N,N/2,n_1,k)=\frac{C_k^{n_1}C_{N/2-k}^{n_2}}{C_{N/2}^{N}}=\frac{\dfrac{n_1!}{k!(n_1-k)!}\dfrac{n_2!}{(N/2-k)!(n_2-(N/2-k))!}}{\dfrac{N!}{N/2!(N-N/2)!}} \tag{5.7.1536}$$

Therefore, we can calculate the unilateral cumulative probability of having k. Mood's test is also a purely unilateral test.

✍**Example:**

Consider the two samples:

$$\begin{aligned}&23.4,24.4,24.6,24.9,25.0,26.2,26.3,26.8,26.8,26.9,27.0,27.6,27.7\\&22.5,22.9,23.7,24,24.4,24.5,25.3,26,26.2,26.4,26.7,26.9,27.4\end{aligned} \tag{5.7.1537}$$

The overall median calculated with Microsoft® Excel® 14.0.6123 is 26.10. We have a total of:

$$k=n_1M_n=8 \tag{5.7.1538}$$

Then it comes with Microsoft® Excel® 14.0.6123:

`=HYPGEOM.DIST(8,26/2,13,26,TRUE)=94.24%`

So at a threshold of 5%, we do not reject the null hypothesis (but... being close to the limit this is a bit tedious to conclude that...). If we do the same calculation using the binomial distribution we obtain:

`=BINOM.DIST(8,26/2,0.5,1)=86.65%`

But obviously here the approximation does not apply since a binomial approximation is acceptable in practice when the sample is about 10 times smaller than the population.

Remark

Unfortunately, there are several versions of the Mood test. For example, a software such as Minitab compares thanks to a contingency table... the values above or below the median and made a simple chi-square test of independence (Pearson's test) as seen in the section of Numerical Methods.

5.7.9.1.10 Poisson Test (1 sample)

We know that a number of rare events follow a Poisson distribution. We can then allow us as for any other distribution to calculate the cumulative probability in a given interval (bilateral or unilateral).

So if we have a discrete random variable following a Poisson distribution:

$$P_k = \frac{\mu^k}{k!}e^{\mu} \qquad (5.7.1539)$$

We then have to a certain right sided level of confidence α, the closest value n of k satisfying the condition:

$$\sum_{k=0}^{n} \frac{\mu^k}{k!}e^{\mu} \rightarrow 1-\alpha \qquad (5.7.1540)$$

So to find the value n (strictly positive integer or null value) we should reverse the sum, which is not... something funny to do (this is why most spreadsheet softwares do not offer at this day the inverse of the Poisson distribution).

Now recall that we have seen in the section on Sequences and Series, the following Taylor (Maclaurin) series with full integral rest to order $n-1$ around 0 to λ:

$$\sum_{k=0}^{n-1} \frac{\lambda^k}{k!}e^{\lambda} = 1 - \int\limits_0^{\lambda} \frac{1}{2^{k/2-1}\Gamma(k/2)} x^{k/2-1}e^{-x/2}\mathrm{d}x \qquad (5.7.1541)$$

Result we had also given in the form of functions for Microsoft® Excel® 14.0.6123 so that the reader can verify this equivalence:

`=POISSON(`$x \in \mathbb{N}, \mu$`,TRUE)`
`=1-CHIDIST(`$2\mu, 2(x+1)$`,TRUE)`

Then it follows that in spreadsheets softwares, we can use the inverse chi-square distribution to calculate the inverse of the Poisson distribution with this time however a small nuance: the result will not necessarily be an integer.

If for example we take (always with Microsoft® Excel® 14.0.6123)

```
=1-CHI.DIST(2*20,2*(15+1),TRUE)=15.6513135%
```

The question is then to find the notation for the opposite ... This is then given by (we divide by 2 to fall back on the mean that is the value of interest):

`=CHIINV(1-15.6513135%,2*(15+1))/2=15.53194258`

Finally, the notation of the inverse is relatively natural. Thus, the "1 sample Poissons' test" at a given right sided α level can be written:

$k \leq$`=CHIINV(1-alpha,2*(number of measures+1))/2`

Formally:

$$\boxed{\lambda \leq \frac{\chi^2_{1-\alpha}2(n_{\text{choosed}}+1)}{2}} \tag{5.7.1542}$$

Note however one thing! It seems that some statistical software approximate sometimes with abuse the Poisson distribution by a Normal distribution. Therefore, the unilateral interval is calculated with:

$$\mu \leq \bar{X} + Z_{1_\alpha}\frac{\sigma}{\sqrt{n}} \tag{5.7.1543}$$

But with the Poisson distribution, remember that we have:

$$\begin{aligned} \mu = \sigma^2 &= \lambda \\ \bar{X} &= \hat{\lambda} \end{aligned} \tag{5.7.1544}$$

Therefore:

$$\lambda = \hat{\lambda} + Z_{1-\alpha}\sqrt{\frac{\lambda_{\text{choosed}}}{n}} \tag{5.7.1545}$$

✍**Example:**

A company manufactures televisions in a constant quantity and has measured the number of defective product produced each quarter for the past ten years (so 4 times 10 measures). The stakeholders determines the maximum acceptable number of defective units is 20 per quarter and wants to determine if the production satisfies these requirements (under the assumption that the distribution of defective follow a Poisson distribution) at a confidence level of 5%.

The 40 measures give us an average of:

$$\bar{X} = \hat{\lambda} = 17.825 \tag{5.7.1546}$$

Then we have with the rough approximation:

$$\lambda = 17.825 + Z_{1-5\%}\sqrt{\frac{20}{40}} \tag{5.7.1547}$$

Either in a spreadsheet software like Microsoft® Excel® 14.0.6123:

```
=NORM.S.INV(1-5%)*SQRT(20/40)+17.825=18.988
```

or:

$$\lambda \leq \frac{\chi^2_{1-5\%}2(20+1)}{2} \tag{5.7.1548}$$

Either in a spreadsheet software like Microsoft® Excel® 11.8346:

```
=CHIINV(1-5%,2*(20+1))/2=14.072
```

In both cases, we are below the imposed average of 2 (so we reject the null hypothesis that the number of defects is greater than or equal to 20). Obviously, it is possible for each of the methods to determine what should be the cumulative probability (confidence level) which brings us to the 20 limit (therefore the $p$value in other words on which we will come back further below). With the first method, aka Normal approximation, the p-value (see page 948) is 0.104%.

Obviously, in the bilateral case, we have:

$$\boxed{\frac{\chi^2_{\alpha/2}2(n+1)}{2} \leq \lambda \leq \frac{\chi^2_{1-\alpha/2}2(n+1)}{2}} \tag{5.7.1549}$$

Example:

An airline company had 2 crash on $1,000,000$ flights (very rare event). What is two-sided the confidence at the level of 95% knowing that globally the number of accidents per million is 0.4.

We have therefore:

$$\frac{\chi^2_{5\%/2}2(2+1)}{2} \leq \lambda \leq \frac{\chi^2_{1-5\%/2}2(2+1)}{2} \tag{5.7.1550}$$

Either the upper bound with a spreadsheet software like Microsoft® Excel® 11.8346 is given by:

```
=CHIINV(1-5%/2,2*(2+1))/2=7.224
```

and for the lower bound:

```
=CHIINV(1-5%/2,2*(2+1))/2=0.618
```

So statistically, the company is less secure than all companies.

5.7.9.1.11 Poisson Test (2 samples)

We have just seen that:

$$\frac{\chi^2_{\alpha/2}2(n+1)}{2} \leq \lambda \leq \frac{\chi^2_{1-\alpha/2}2(n+1)}{2} \tag{5.7.1551}$$

However, following the same reasoning that led us to construct the following test of average comparison:

$$(\bar{X}_2-\bar{X}_1)-Z_{\alpha/2}\sqrt{\frac{\sigma_1^2}{n_1}+\frac{\sigma_2^2}{n_2}} \leq \mu_2-\mu_1 \leq (\bar{X}_2-\bar{X}_1)+Z_{\alpha/2}\sqrt{\frac{\sigma_1^2}{n_1}+\frac{\sigma_2^2}{n_2}} \tag{5.7.1552}$$

or its equivalent with the Student distribution when the true standard deviation is not known and using the fact that we have shown that the Poisson distribution is stable by the addition (and hence by subtraction), that Gamma distribution was also stable by the addition (and therefore by subtraction) and also the chi-square distribution since it is only a special case of the gamma distribution, we tend to write perhaps a little bit to fast the extension of what we have seen before:

$$\frac{\chi^2_{\alpha/2}(2(n_2+1)-2(n_1+1))}{2} \leq \lambda_2-\lambda_1 \leq \frac{\chi^2_{1-\alpha/2}(2(n_2+1)-2(n_1+1))}{2} \tag{5.7.1553}$$

And in the facts this is a trap as say some practitioners ... because the chi-square distribution has a support which is defined as being strictly positive and the confidence interval could naturally have a negative left terminal (... O_o). One solution could be to use the test of the difference of two proportions that we have already discussed earlier:

$$Z \cong \frac{(\hat{p}_X-\hat{p}_Y)-\mu}{\sqrt{\dfrac{\hat{p}_X(1-\hat{p}_X)}{n_1}+\dfrac{\hat{p}_Y(1-\hat{p}_Y)}{n_2}}} \tag{5.7.1554}$$

Of course, only in the case that the conditions for approaching the test with a Normal distribution are met (proportions have to be typically less than 0.1 and no greater than 50).

Most softwares seem to have implemented this latter method (with which I do not necessarily agree).

✍**Example:**

An airline company had 2 airplanes crash was in $1,000,000$ flights (very rare event). Another company had 3 crashes in $1,200,000$ flights. What is the two sided confidence interval at the level of 95% assuming that the difference is zero.

Therefore, the proportions are:

$$\hat{p}_X=\frac{2}{n_1}=\frac{2}{1,000,000}=0.000002 \quad \text{and} \quad \hat{p}_Y=\frac{3}{n_2}=\frac{3}{1,200,000}=0.0000025 \tag{5.7.1555}$$

We write:

$$\begin{aligned}\Delta&=\hat{p}_X-\hat{p}_Y=-0.0000005\\ \hat{q}_X&=1-\hat{p}_X\\ \hat{q}_Y&=1-\hat{p}_Y\end{aligned} \tag{5.7.1556}$$

Then we have:

$$\Delta-Z_{5\%/2}\sqrt{\frac{\hat{p}_X\hat{q}_X}{n_1}+\frac{\hat{p}_Y\hat{q}_Y}{n_2}}\leq\mu\leq\Delta+Z_{5\%/2}\sqrt{\frac{\hat{p}_X\hat{q}_X}{n_1}+\frac{\hat{p}_Y\hat{q}_Y}{n_2}} \tag{5.7.1557}$$

which gives a confidence interval for the expected theoretical proportion difference:

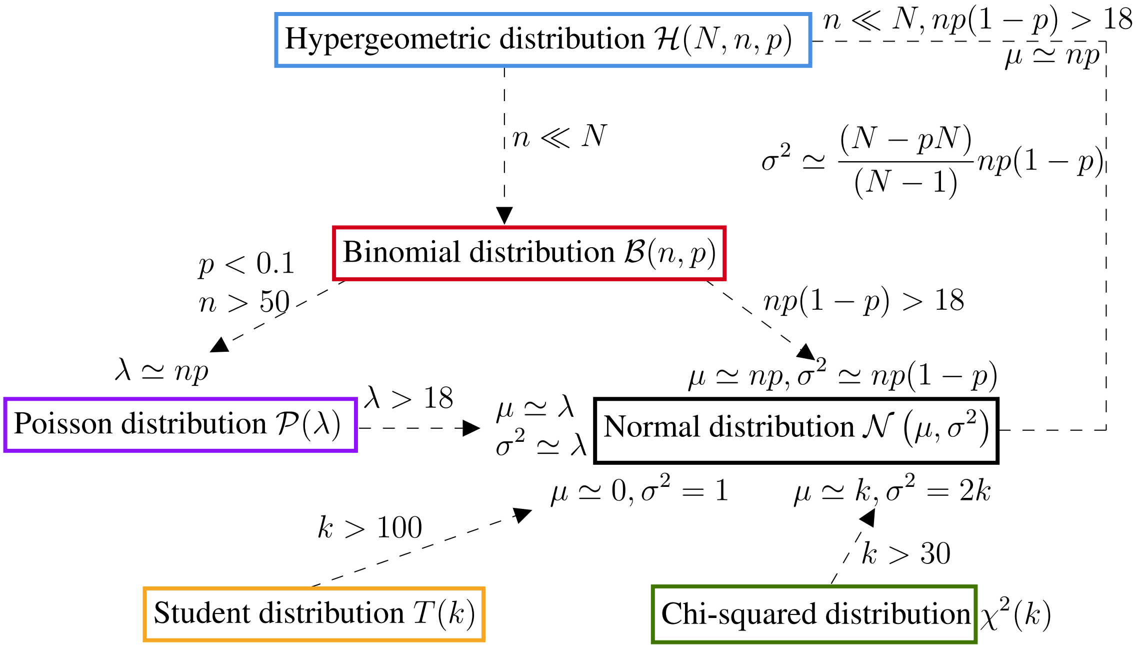
$$-0.000004461\leq\mu\leq 0.000003461 \tag{5.7.1558}$$

and therefore as -0.0000005 is in this interval, we accept the hypothesis as the difference of proportions are not statistically significant at the threshold of 5%.

Or taking the non approximated expression, we have (with the same conclusion):

$$\begin{gathered}\frac{\chi^2_{5\%/2}(2(3+1)-2(2+1))}{2}\leq\lambda_2-\lambda_1\leq\frac{\chi^2_{1-5\%/2}(2(3+1)-2(2+1))}{2}\\ \Downarrow\\ 0.0253\leq\mu\leq 3.6889\end{gathered}$$

So to summarize some convergence of distributions in all these different tests and intervals that we have seen so far, we offer the reader the following diagram that we hope... will clarify perhaps more or less things:



Hypergeometric distribution $\mathcal{H}(N,n,p)$
$n \ll N, np(1-p) > 18$
$\mu \simeq np$
$n \ll N$
$\sigma^2 \simeq \dfrac{(N-pN)}{(N-1)} np(1-p)$
Binomial distribution $\mathcal{B}(n,p)$
$p < 0.1$
$n > 50$
$np(1-p) > 18$
$\lambda \simeq np$
$\mu \simeq np, \sigma^2 \simeq np(1-p)$
Poisson distribution $\mathcal{P}(\lambda)$
$\lambda > 18$
$\mu \simeq \lambda$
$\sigma^2 \simeq \lambda$
Normal distribution $\mathcal{N}(\mu, \sigma^2)$
$\mu \simeq 0, \sigma^2 = 1$
$\mu \simeq k, \sigma^2 = 2k$
$k > 100$
$k > 30$
Student distribution $T(k)$
Chi-squared distribution $\chi^2(k)$

Figure 5.164: Convergence of different customary distributions in elementary statistical inference

And also this table where all relations have been demonstrated in detail above, and some already used (others will be used later):

Statistical sampling	Statistic Average	Statistic Standard-Deviation
Mean (infinite population)	μ	$\dfrac{\sigma}{\sqrt{n}}$
Mean (finite population)	μ	$\dfrac{\sigma}{\sqrt{n}}\sqrt{\dfrac{N-n}{N-1}}$
Proportion (finite population)	p	$\sqrt{\dfrac{p(1-p)}{n}}$
Proportion (infinite population)	p	$\sqrt{\dfrac{p(1-p)}{n}}\sqrt{\dfrac{N-n}{N-1}}$
$\hat{\sigma}^2$ (infinite population)	$\dfrac{n-1}{n}\sigma^2$	$\sqrt{\dfrac{2(n-1)}{n^2}}\sigma^2$

Table 5.48: Table of statistical sampling proved earlier and used in part until now

Definition (#5.7.137): In Bayesian terms "abduction" is the process of finding the shortest prior hypothesis, technically named the "Minimum Description Length" (MDL) (but also known under the name of "Occam's razor") that explains the best the data. With induction, we are often trying to figure out what will be most likely in the future. With abduction, we are often trying to figure out what best explains something that already occurred.

5.7.9.1.12 Confidence/Tolerance/Prediction/Credibility Intervals

Here we go and in order to avoid frequent confusion and before moving on to more complex subjects, we will compare the confidence interval, the credibility interval, the tolerance interval (often named "fluctuation interval" in some school programs) and finally the prediction interval.

Definitions (#5.7.138):

D1. The "tolerance interval" (or "fluctuation interval"), from the statistician point of view[47], is an interval containing a certain percentage (usually $68.26, 95.44$ or 99.73% in the case of a Normal distribution) of individuals in a population of measures.

D2. The "confidence interval" for a sample mean (or a sample proportion) must be read as the percentage of similarly constructed confidence intervals (usually $90, 95$ or 99% in the two sided case) that will contain the true expected mean (or true expected proportion) knowing the measurement data a posteriori.

D3. The "credibility interval" for a sample mean (or proportion p) is the interval value to a given probability level (usually $90, 95$ or 99% in the two sided case) for the expected mean (true average) or the proportion of the population where we have special prior for the mean/standard deviation or for the proportion (see further below page 910).

D4. The "prediction interval" is used to determine an interval for a single value based on the knowledge of the sample mean and the standard deviation of the population.

An example being more often better than a thousand words, consider the case where the mean and the standard deviation of prices are 49 DVD are given by:

$$\bar{X}=\hat{\mu}=31.5531 \quad S=\hat{\sigma}=0.7992 \tag{5.7.1559}$$

Therefore we have:

$$\begin{aligned}[\bar{X}\pm S]&=[30.8,32.4]\\ [\bar{X}\pm 2S]&=[30.0,33.2]\\ [\bar{X}\pm 3S]&=[29.2,34.2]\end{aligned} \tag{5.7.1560}$$

corresponding to the tolerance intervals according to a Normal distribution of $68.26, 95.44$ and 99.73%.

But a confidence interval of 95% based on the relation proved above:

$$\bar{X}-\frac{S}{\sqrt{n}}T_{\alpha/2}(n-1)\leq\mu\leq\bar{X}-\frac{S}{\sqrt{n}}T_{\alpha/2}(n-1) \tag{5.7.1561}$$

gives:

$$31.32\leq\mu\leq 31.78 \tag{5.7.1562}$$

---

[47] At the opposite of that of the mechanical engineer where the tolerance interval is obviously something the measurement interval in which a piece will not be rejected from the production.

So 95% cumulative probability that the true mean is between 31.32 and 31.78.

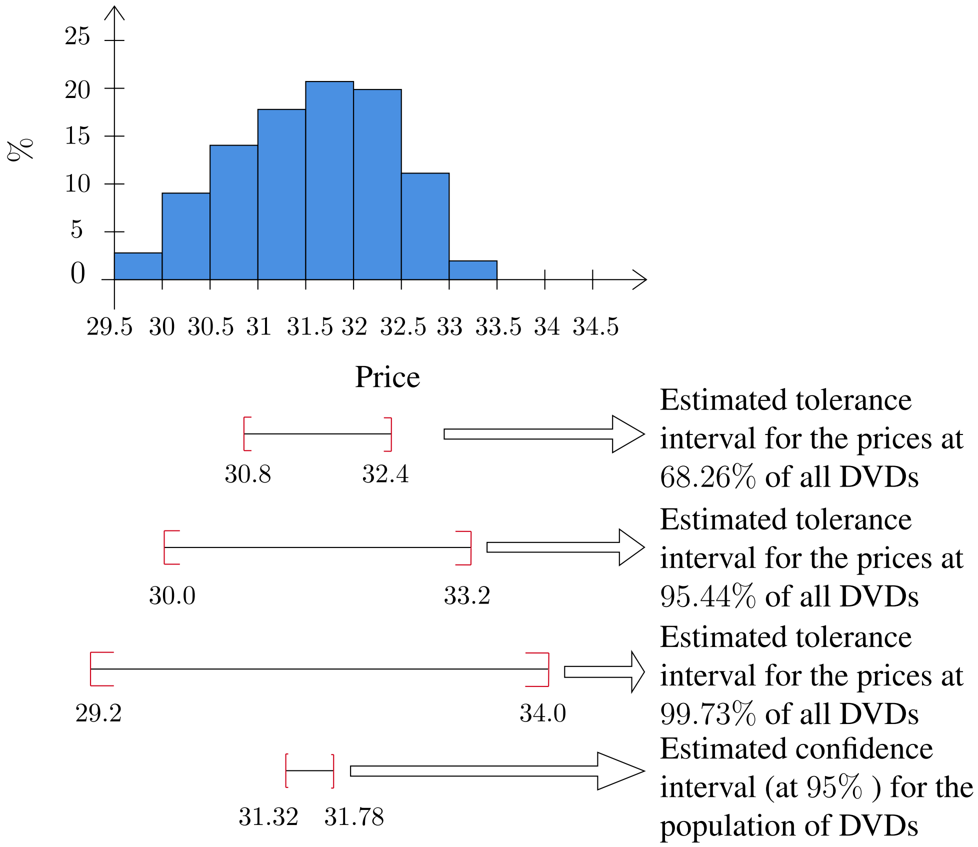


Figure 5.165: **Histogram of the prices of a sample of** 49 **DVDs**

Now lets us introduce a new concept that is rarely addressed in the statistics literature. The idea of the prediction interval is rather than look at the confidence interval of the mean based on an experimental average, to use this experimental average (sample mean) as a basis for predicting the interval of a single value (and not of the average!).

We'll look at the difference between the mean and a punctual value:

$$\bar{x}-x \qquad (5.7.1563)$$

that we will assume close to zero (it is better to have a reliable product and pass the tests to obtain the authorization of sales...). About the variance, what interests us is not just the standard deviation of the mean anymore, but the standard deviation of the difference... and as the sample is independent of the unique value we have:

$$\sigma_{\bar{x}-x}^2=\sigma_{\bar{x}}^2+\sigma_x^2=\frac{\sigma^2}{n}+\sigma^2=\sigma^2\left(1+\frac{1}{n}\right) \qquad (5.7.1564)$$

So we can write as a first approximation:

$$Z\cong\frac{\bar{x}-x}{\sigma_{\bar{x}-x}^2}=\frac{\bar{x}-x}{\sqrt{\sigma^2\left(1+\dfrac{1}{n}\right)}}=\frac{\bar{x}-x}{\sigma\sqrt{1+\dfrac{1}{n}}} \qquad (5.7.1565)$$

And of course after what we saw:

$$T(n-1)\cong\frac{\bar{x}-x}{S\sqrt{1+\dfrac{1}{n}}} \tag{5.7.1566}$$

So we can build verbatim the prediction interval:

$$\boxed{\bar{x}-T_{\alpha/2}(n-1)S\sqrt{1+\frac{1}{n}}\leq x\leq\bar{x}+T_{\alpha/2}(n-1)S\sqrt{1+\frac{1}{n}}} \tag{5.7.1567}$$

5.7.9.2 Bayesian Inference

To understand the idea of "Bayesian inference" (to not be confuse with "Bayesian Hypothesis Testing") remember that in the non-Bayesian (frequentist) approach we measure for example a parameter θ. Afterwards, we calculate the standard error or a confidence interval on which we perform a hypothesis test.

In the Bayesian approach we assume that the parameter θ follows a non-trivial prior distribution. We then calculate its posterior probability distribution knowing the measurements made and we calculate afterwards a confidence interval on that latter posterior.

According to some specialists there is now a plenty of theorem and masses of worked-out numerical examples that shows evidence of the superiority of the Bayesian method in a hundred of different areas! The traditional frequentist methods which use only sampling distributions are usable and useful in many particularly simple, idealized problems; however, they represent the most proscribed special cases of probability theory, because they presuppose conditions (independent repetitions of a random experiment but no relevant information!) that are hardly ever met in real problems.

Remark

The frequentist approach is the case of what we also name "uninformative prior". But to reader must not think that a uniform law prior is an example of uninformative prior (there is a detailed mathematical example further below just after our study of beta-binomial posterior)!!! Indeed, the pure frequentists doesn't make ANY prior (i.e. the probability is completely indeterminate $0/0$)! The pure frequentist always assumes that the sample data is exactly representative of the population because that's all it can do.

Let us assume that we have an univariate bayesian model with a likelihood $P(y|\vec{\theta})$ (also sometimes denoted $f(y|\vec{\theta})$) and an univariate prior distribution $P(\vec{\theta})$ (also sometimes denoted $f(\vec{\theta})$).

Let us recall that (according to what we have seen during our study of Bayesian probabilities page 486) if we multiply the univariate likelihood $P(y|\vec{\theta})$ and the univariate prior probability $P(\vec{\theta})$ we get the univariate posterior distribution $P(\vec{\theta}|y)$ (also denoted $\pi(\vec{\theta}|y)$). Indeed, using what we have seen earlier above we get (the denominator is for recall the "marginal probability" or also sometimes named the "evidence"):

$$\boxed{\text{Posterior}=P(\vec{\theta}|y)=\frac{\text{likelihood}\cdot\text{prior}}{\text{marginal}}=\frac{P(y|\vec{\theta})P(\vec{\theta})}{P(y)}\propto P(y|\vec{\theta})P(\vec{\theta})} \tag{5.7.1568}$$

where $P(y|\vec{\theta})P(\vec{\theta})$ is commonly named the "unnormalized posterior density".

Also often denoted (still in the univariate case and using the definition of marginal distribution):

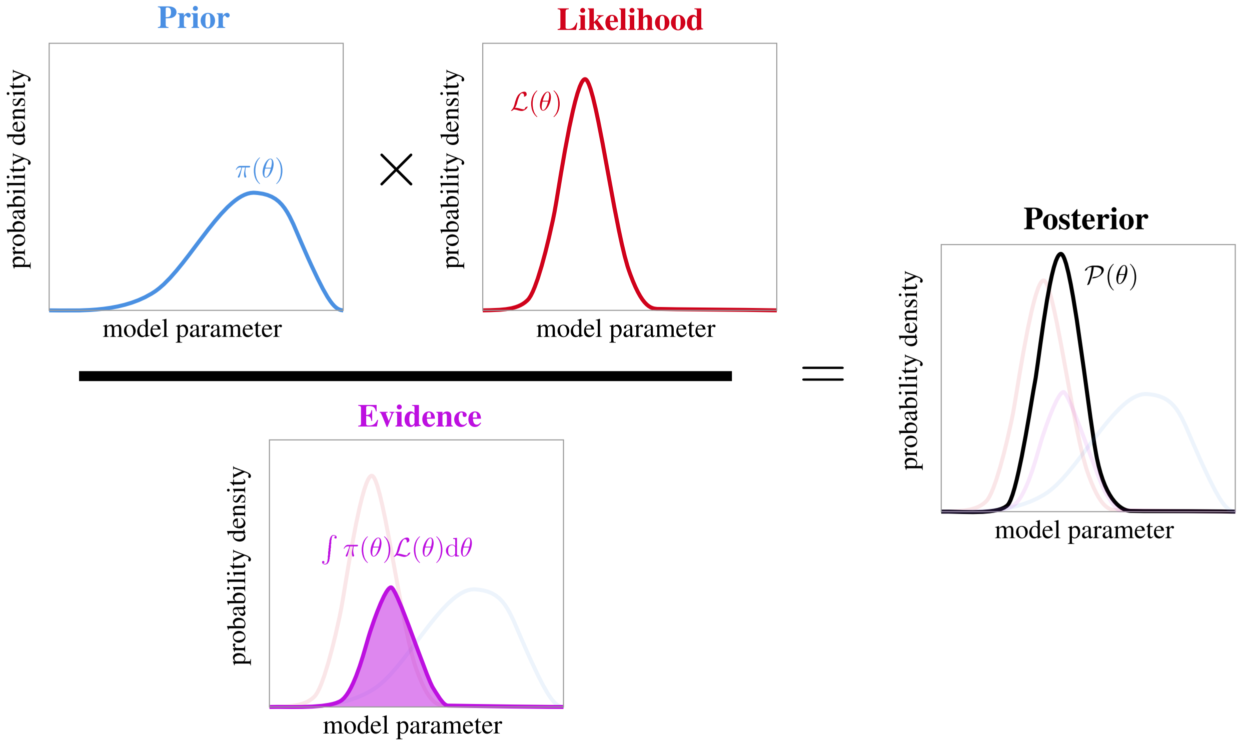
$$\boxed{\pi(\vec{\theta}|y)=\frac{\ell(y|\vec{\theta})f(\vec{\theta})}{f(y)}=\frac{\ell(y|\vec{\theta})f(\vec{\theta})}{\int f(y,\vec{\theta})\mathrm{d}p}\propto f(y|\vec{\theta})f(\vec{\theta})} \tag{5.7.1569}$$

Where the ratio:

$$\frac{\ell(y|\vec{\theta})}{f(y)} \tag{5.7.1570}$$

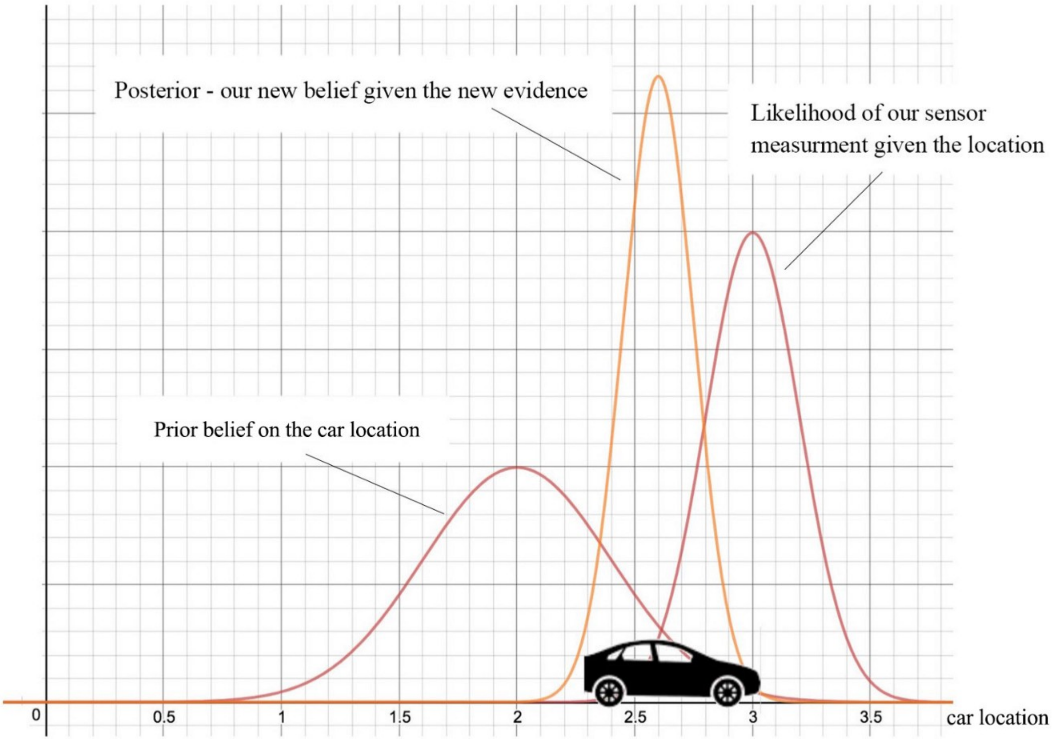
is sometimes named the "standardized likelihood".

With the exception of the marginal probability, posterior, prior and likelihood are not a point estimate. They are curves as illustrated below:



Prior
probability density
$\pi(\theta)$
model parameter
×
Likelihood
probability density
$\mathcal{L}(\theta)$
model parameter
=
Posterior
probability density
$\mathcal{P}(\theta)$
model parameter
Evidence
probability density
$\int \pi(\theta)\mathcal{L}(\theta)\mathrm{d}\theta$
model parameter

Or, in the example below, we show the probability density function (PDF) on different car locations:



We strongly recommend the reader to see the examples below for a better understanding of the denominator.

Definition (#5.7.139): A prior $P(\vec{\theta})$ for a sampling model is named a "conjugate prior" if the resulting posterior denoted traditionally $\pi(\vec{\theta}|\vec{y})$ (for multivariate case) is in the same distributional family as the prior.

In other words: if our posterior distribution is of the same family as the prior distribution, we speak of "conjugation of distributions". Then we also say that the prior function is the "conjugation of the likelihood" (in practice it is however the exception rather than the rule ...).

Here is for example a table summarizing the most classic cases:

Likelihood	Prior	Posterior
Binomial	Beta	(Beta-)Binomial distribution
Binomial	Binomial	Binomial distribution
Negative Binomial	Beta	(Beta-)Negative Binomial distribution
Poisson	Gamma	(Poisson-)Gamma distribution
Geometric	Beta	(Beta-)Geometric distribution
Normal (unknown mean)	Normal	Normal distribution
Normal (unknown variance)	Inverse Gamma	(Normal-)Gamma inverse distribution
Normal (all moments known)	Normal/Gamma	Normal/Gamma distribution
Multinomial	Dirichlet	(Multinomial-)Dirichlet distribution

However (and as always!) in this textbook we will detail only the conjugations that have practical applications in other chapters!

A last reminder before continuing. If we know for a given likelihood distribution the expression $P(y_i/\vec{\theta})$, then for a vector of independent realizations of a random variable, the total likelihood is equal to the product of the probabilities:

$$P(\vec{y}|\vec{\theta}) = P(y_1, \ldots, y_i, \ldots, y_n|\vec{\theta}) = \prod_{i=1}^{n} P(y_i|\vec{\theta}) \tag{5.7.1571}$$

Be careful with Bayesian inference! Don't trust absolutely intuition, for even simple prior plus likelihood scenarios defy it! The quartet below shows that the choice of prior and likelihood distribution matters a lot. More specifically the "tailed-ness" of the distribution matters more!!

The author of this quartet depicts four cases:

- Normal prior, Normal likelihood (all is fine here)
- T-distribution prior, T-distribution likelihood (things start to go awry, we now have a bimodal posterior)
- T-distribution prior, Normal likelihood (the posterior mimics the likelihood and in a way, prior had absolutely no sway)
- Normal prior, T-distribution likelihood (the posterior mimics the prior and in a way likelihood had absolutely no sway)

Therefore the Bayesian inference requires a lot of hardwork and knowledge to get it right.

Richard McElreath's Quartet

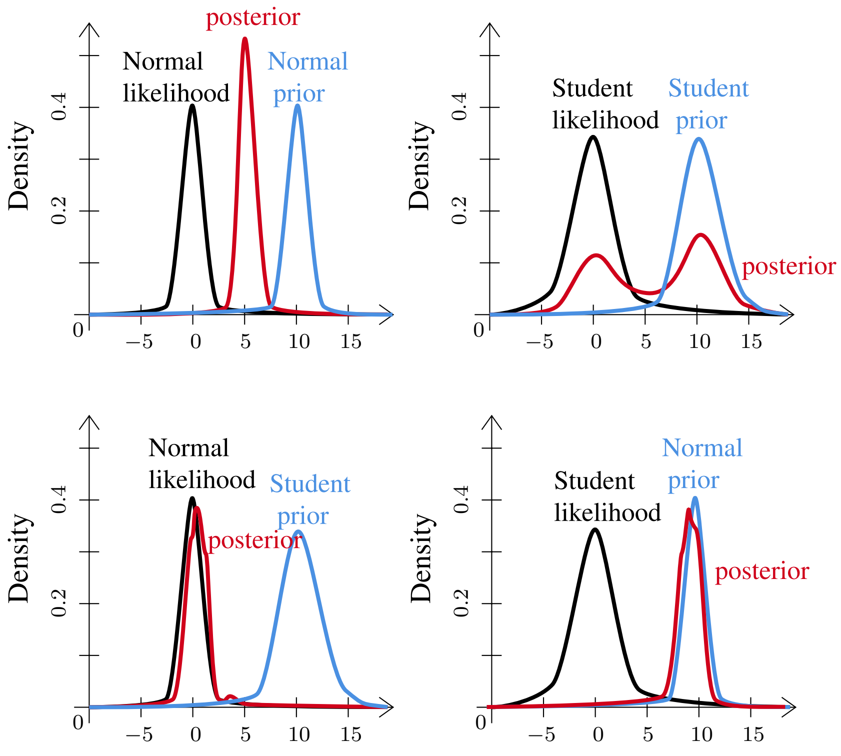


Figure 5.166: Richard McElreath's Quartet

5.7.9.2.1 Beta prior conjugate to Binomial likelihood (beta-binomial distribution)

Let us now introduce the beta-binomial distribution that is used a lot in Engineering but also in Bayesian statistics (especially known for the famous A/B test for example!).

We decide to start with this distribution have a binomial likelihood because it is a law with only one parameter and pedagogically it seems more judicious to start with that latter rather that with a Normal likelihood which has two parameters (furthermore there are three possible conjugates for the Normal likelihood as shows in the above table).

Definition (#5.7.140): The "beta-binomial distribution" is the binomial distribution in which the probability p of success at each trial is fixed but randomly drawn from a beta distribution prior to n Bernoulli trials.

Let us now prove that the Beta distribution is a conjugate distribution of the binomial distribution, but before a definition!

Suppose we observe n independent Bernoulli random variable $x_1,\ldots,x_n$. We wish to estimate the success probability p with the Bayesian approach. We will use a beta $P_{a,b}$ priori for p (as $P_{a,b}\in]0,1[$ it may be a good choice...) and prove this is a conjugate prior.

First using the relationship between the Euler Gamma function and the factorial (see section Differential and Integral Calculus page 1574) we have using the conventional notation (since the probability of the prior is assumed independent of the trial itself we then multiply both probabilities):

$$\begin{aligned}\pi(\vec{\theta}|y)&\propto P(y|\vec{\theta})P(\vec{\theta})=P(y|p,n)P(p,a,b)=\mathcal{B}(n,y)P_{a,b}=\mathcal{B}(n,y)\frac{p^{a-1}(1-p)^{b-1}}{B(a,b)}\\&=\left(\binom{n}{y}p^y(1-p)^{n-y}\right)\left(\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}p^{a-1}(1-p)^{b-1}\right)\\&=\frac{n!}{y!(n-y)}p^y(1-p)^{n-y}\left(\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}p^{a-1}(1-p)^{b-1}\right)\\&=\frac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}p^{y+a-1}(1-p)^{n-y+b-1}\end{aligned} \tag{5.7.1572}$$

Notice that we also have the following equivalent result (just the notation differs!):

$$\begin{aligned}\pi(p(a,b)|y,n)&\propto P(y,n|p(a,b))P(p(a,b))=\mathcal{B}(n,y)P_{a,b}\\&=\left(\binom{n}{y}p^y(1-p)^{n-y}\right)\left(\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}p^{a-1}(1-p)^{b-1}\right)\\&=\binom{n}{y}\frac{p^{y+a-1}(1-p)^{n-y+b-1}}{B(a,b)}\end{aligned} \tag{5.7.1573}$$

Although it is not really necessary, let us derive the marginal density of y (in purpose to normalize the posterior density further below!):

$$\begin{aligned}P(y)&=\int\limits_0^1 f(y,n,p(a,b))\mathrm{d}p\\&=\frac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\int\limits_0^1 p^{y+a-1}(1-p)^{n-y+b-1}\mathrm{d}p\\&=\frac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\frac{\Gamma(y+a)\Gamma(n-y+b)}{\Gamma(n+a+b)}\int\limits_0^1\frac{\Gamma(n+a+b)}{\Gamma(y+a)\Gamma(n-y+b)}p^{y+a-1}(1-p)^{n-y+b-1}\mathrm{d}p\\&=\frac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\frac{\Gamma(y+a)\Gamma(n-y+b)}{\Gamma(n+a+b)}\end{aligned} \tag{5.7.1574}$$

That latter marginal density is also sometimes written:

$$\begin{aligned}P(y)&=\int\limits_0^1 f(y,p(a,b))\mathrm{d}p=\int\limits_0^1 \mathcal{B}(n,y)P_{a,b}\mathrm{d}p\\&=\int\limits_0^1\binom{n}{y}\frac{p^{y+a-1}(1-p)^{n-y+b-1}}{B(a,b)}\mathrm{d}p=\binom{n}{y}\frac{\int\limits_0^1 p^{y+a-1}(1-p)^{n-y+b-1}\mathrm{d}p}{B(a,b)}\end{aligned} \tag{5.7.1575}$$

So a common (wrong) definition of the beta-binomial distribution is given by these two equivalent relations of the marginal density:

$$\boxed{P(y)=\frac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\frac{\Gamma(y+a)\Gamma(n-y+b)}{\Gamma(n+a+b)}=\binom{n}{y}\frac{\int\limits_0^1 p^{y+a-1}(1-p)^{n-y+b-1}\mathrm{d}p}{B(a,b)}} \tag{5.7.1576}$$

Now let us focus on the posterior $\pi(\vec{\theta},y)$ (i.e. the "real" expression of the beta-binomial distribution), then given by:

$$\begin{aligned}\pi(p(a,b)|y,n)&=\frac{P(y|p(a,b))P(p(a,b))}{P(y)}=\frac{\dfrac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\dfrac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}p^{y+a-1}(1-p)^{n-y+b-1}}{\dfrac{\Gamma(n+1)}{\Gamma(y+1)\Gamma(n-y+1)}\dfrac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)}\dfrac{\Gamma(y+a)\Gamma(n-y+b)}{\Gamma(n+a+b)}}\\&=\frac{\Gamma(n+a+b)}{\Gamma(y+a)\Gamma(n-y+b)}p^{y+a-1}(1-p)^{n-y+b-1}=\frac{p^{y+a-1}(1-p)^{n-y+b-1}}{B(y+a,n-y+b)}\end{aligned} \tag{5.7.1577}$$

That latter equality is sometimes denoted:

$$\pi(p(a,b)|y,n)=\frac{p^{s+\alpha-1}(1-p)^{f+\beta-1}}{B(s+\alpha,f+\beta)} \tag{5.7.1578}$$

Clearly this posterior is a beta distribution $P_{a,b}(y+a, n-y+b)$. So we see that only the parameters of the beta prior change into now "hyper-parameters" of a beta posterior! In other words, this means that if the likelihood function is binomial, then a beta prior gives a beta posterior!

Notice that we then quickly get by extension (when drawing N items among the n):

$$\begin{aligned}\pi(p(a,b)|\vec{y},n) &= \prod_{i=1}^{N} \frac{\Gamma(n+a+b)}{\Gamma(y_i+a)\Gamma(n-y_i+b)} p^{y_i+a-1}(1-p)^{n-y_i+b-1} \\ &= P_{a,b}\left(\sum_i^N y_i + a, nN - \sum_i^N y_i + b\right)\end{aligned} \tag{5.7.1579}$$

That latter relation is sometimes denoted $\text{Bbin}(a,b,n)$.

Remark

The worst is that some authors in the field of reliability engineering denote the cumulated probability that $y < n - F$ where F is the number of failures as following (see section Industrial Engineering page 9059):

$$P_{a,b}\left((n-F)+1, n-(n-F)+b\right) = B(n-F+1, F+b) \tag{5.7.1580}$$

Then it does not become obvious at all out of context to know if we are dealing with a mass density or distribution function.

An interesting case to consider is when we have no particular premonition about prior distribution. Therefore, we can take a function that has the same probability for all values in the $[0,1]$ interval of the p parameter of the binomial distribution.

Therefore, the beta function can always be kept as a distribution a priori since it is reduced to the uniform case:

$$P_{a,b} = P_{1,1} = \frac{\Gamma(2)}{\Gamma(1)\Gamma(1)} p^{1-1}(1-p)^{1-1} 1_{]0,1[} = 1 \cdot 1_{]0,1[} \tag{5.7.1581}$$

which is therefore a continuous uniform distribution in the interval $[0,1]$. Hence the posterior function of the parameter p is given by:

$$\pi(p(1,1)|\vec{y},n) = P_{1,1}\left(\sum_i^N y_i + 1, nN - \sum_i^N y_i + 1\right) \tag{5.7.1582}$$

Let us calculate now the expected mean and variance of the beta binomial distribution using[48] the law of total expectation (see page 501) and the law of total variance (page 502):

$$\text{E}(Y) = \text{E}(\text{E}(Y|\pi)) \qquad \text{V}(Y) = \text{E}(\text{V}(Y|\pi)) + \text{V}(\text{E}(Y|\pi)) \tag{5.7.1583}$$

Expectation and variance for the binomial distribution are assumed to be so well known that we will not mention them here (see page 658), and for the beta distribution we have (see page 760):

$$\text{E}(\pi) = \frac{a}{a+b} \qquad \text{V}(\pi) = \frac{ab}{(a+b)^2(a+b+1)} \tag{5.7.1584}$$

---

[48] There are other (complicated) ways to derive expectation and variance, but if you remember these relations, then you have as far as we know the simplest derivation!

Using the law of total expectation , we have:

$$\mathrm{E}(Y)=\mathrm{E}(\mathrm{E}(Y|\pi))=\mathrm{E}(np)=n\mathrm{E}(p)=n\mathrm{E}(\pi)=\frac{na}{a+b} \tag{5.7.1585}$$

and using the law of total variance, we have (in the second line we used the Huygens relation):

$$\begin{aligned}\mathrm{V}(Y)&=\mathrm{E}(\mathrm{V}(Y|\pi))+\mathrm{V}(\mathrm{E}(Y|\pi))=\mathrm{E}(np(1-p))+\mathrm{V}(np)\\&=n\mathrm{E}(p)-n\mathrm{E}(p^2)+n^2\mathrm{V}(p)=n\left(\mathrm{E}(p)-\mathrm{V}(p)-\mathrm{E}(p)^2+n\mathrm{V}(p)\right)\\&=n\left(\frac{a}{a+b}-\frac{ab}{(a+b)^2(a+b+1)}-\left(\frac{a}{a+b}\right)^2+n\frac{ab}{(a+b)^2(a+b+1)}\right)\\&=n\left(\frac{a(a+b)(a+b+1)}{(a+b)^2(a+b+1)}-\frac{ab}{(a+b)^2(a+b+1)}-\frac{a^2(a+b+1)}{(a+b)^2(a+b+1)}+n\frac{ab}{(a+b)^2(a+b+1)}\right)\\&=n\frac{a(a+b)(a+b+1)-ab-a^2(a+b+1)+nab}{(a+b)^2(a+b+1)}\\&=n\frac{(a^2+ab)(a+b+1)-ab-a^3-a^2b-a^2+nab}{(a+b)^2(a+b+1)}\\&=n\frac{a^3+a^2b+a^2+a^2b+ab^2+ab-ab-a^3-a^2b-a^2+nab}{(a+b)^2(a+b+1)}\\&=n\frac{a^2b+ab^2+nab}{(a+b)^2(a+b+1)}=\frac{nab(a+b+n)}{(a+b)^2(a+b+1)}\end{aligned} \tag{5.7.1586}$$

So to summarize we have for posterior expectation and posterior variance:

$$\mathrm{E}(Y)=\frac{na}{a+b}\qquad\mathrm{V}(Y)=\frac{nab(a+b+n)}{(a+b)^2(a+b+1)} \tag{5.7.1587}$$

If we reintroduce p, this can we be written:

$$\mathrm{E}(Y)=np\qquad\mathrm{V}(Y)=np(1-p)\frac{a+b+n}{a+b+1} \tag{5.7.1588}$$

We notice that the variance is higher than for the corresponding binomial distribution. We say then that there is "over-dispersion".

Remark

In case of $a=b=0.5$ for the beta distribution, it is quite common to speak about the "Jeffreys prior".

5.7.9.2.1.1 Uninformative prior

When prior distributions have no population basis, they can be difficult to construct, and there has long been a desire for prior distributions that can be guaranteed to play a minimal role in the posterior distribution. Such distributions are sometimes named "reference prior distributions", and the prior density is described as "uninformative prior" or "noninformative prior". The rationale for using noninformative prior distributions is often said *to be to let the data speak for themselves*, so that inferences are unaffected by information external to the current data.

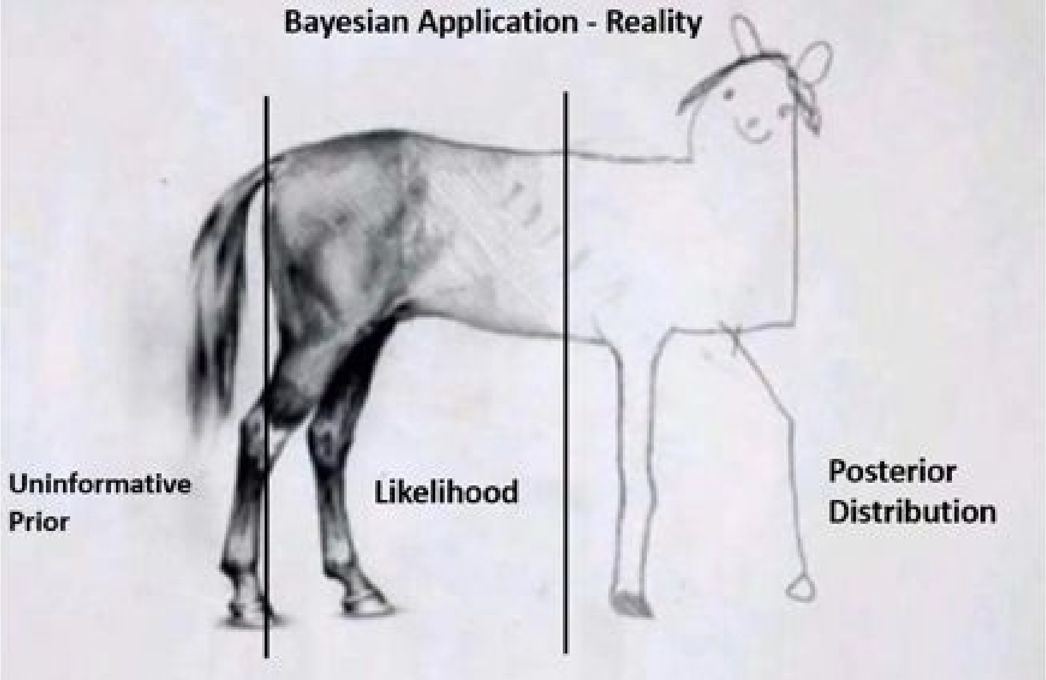

Figure 5.167: **Depending on the choice of the uninformative prior and likelihood sometimes things can go very wrong**

Some people would expect a uniform prior to be a good example of an uninformative prior and get the same result as the frequentist approach. However, this is not the case[49]!

As an example, let's look the classical Bernoulli problem - you flip coins and s are heads, f are tails.

We want to predict p, the probability of heads on any given coin flip.

The frequentist approach is to say that p is simply $s/(s+f)$. In this approach, we assume nothing about the distribution of p and we're simply finding the maximum likelihood estimate. This makes sense!

Now, let's adopt the Bayesian approach and assume we say:

$$P(p|\text{data}) = \frac{P(\text{data}|p)\cdot P(p)}{P(\text{data})} \qquad (5.7.1589)$$

As we have proved it earlier above at page 898 if we make our prior the beta distribution, we get:

$$P(p|\text{data}) = \frac{p^{s+\alpha-1}(1-p)^{f+\beta-1}}{B(s+\alpha,f+\beta)} \qquad (5.7.1590)$$

---

[49] For reasons unknown to us yet, even String theory physicists seems to use the uniform distribution as "natural choice" (naturalness criteria) for uninformative prior. A first attempt to justify the uniform probability distribution for the naturalness criterion might be to say that it doesn't introduce additional parameters into the String theory. But of course it does: it introduces the number 1 as a typical width! Some physicists, however argue without evidence yet, that 1 satisfy naturalness criterion...

Now let's say we want to find the expected value of p:

$$\begin{aligned}\mathrm{E}(p|\text{data})&=\int\limits_0^1 P(p|\text{data})p\mathrm{d}p=\int\limits_0^1 \frac{p^{s+\alpha-1}(1-p)^{f+\beta-1}}{B(s+\alpha,f+\beta)}p\mathrm{d}p\\&=\int\limits_0^1 \frac{p^{s+\alpha}(1-p)^{f+\beta-1}}{B(s+\alpha,f+\beta)}\mathrm{d}p=\frac{B(s+\alpha+1,f+\beta)}{B(s+\alpha,f+\beta)}\end{aligned} \tag{5.7.1591}$$

We fall back obviously on the same expression of the expected mean as the beta distribution (as it is a conjugate prior!). Hence we can do the same simplification:

$$\mathrm{E}(p|\text{data})=\frac{B(s+\alpha+1,f+\beta)}{B(s+\alpha,f+\beta)}=\frac{s+\alpha}{s+\alpha+f+\beta} \tag{5.7.1592}$$

Makes sense so far! Now, let's say we want to choose a really "objective" prior to emulate the frequentist approach, like a uniform distribution. This is equivalent to $B(1,1)$ as we have proved it during our study of the Beta distribution. In this case, we would get:

$$\mathrm{E}(p|\text{data};\alpha=1,\beta=1)=\frac{s+1}{s+f+2} \tag{5.7.1593}$$

This may hurts the brain of some people! Even though we're being as objective as we can ("p is equally likely to be anything"), we're getting a different result than the frequentist approach.

On the flip side, if we choose what we may consider as an improper prior like $B(0,0)$, we get the same result as the frequentist approach:

$$\mathrm{E}(p|\text{data};\alpha=0,\beta=0)=\frac{s}{s+f} \tag{5.7.1594}$$

What makes $B(0,0)$ more similar to the frequentist approach than $B(1,1)$? What assumption are we making in $B(1,1)$? How is $B(0,0)$ "less informed"? In fact you can't ask this question because it is simply inconsistent by definition!

There is no objective, unique prior that represents ignorance. Instead, reference priors are chosen by public agreement, much like units of length and weight. In this interpretation, reference priors are akin to a default option in a computer package. We fall back to the default when there is insufficient information to otherwise define the prior.

Let us briefly describe below the following classes of non-informative priors:

- **Bayes-Laplace uniform prior**: It's the prior we have introduce just earlier above and that are from Bayes and Laplace (118 and 119th century according to holocene calendar).
- **Jeffreys' prior**: Jeffreys (11946 according to holocene calendar) proposed a method to assign priors that is consistent under re-parametrization (we will give more details about this prior the day we will need it for a practical application in this textbook).
- **Jaynes' maximum entropy prior**: Jaynes (11968 according to holocene calendar) proposed another method to elicit uninformative priors. He argued that the probability distribution which best represents a given state of knowledge can be found by maximizing the entropy of the distribution (see section Statistical Mechanics page 3530), subject to some constraints representing the available information.

- **Bernardo's reference prior**: Bernardo (11979 according to holocene calendar) proposed that as the prior should influence the posterior as little as possible for this to happen, the posterior should be on average very different from the prior. Therefore, a reference prior is derived by maximizing the expected value of the Kullback-Leibler divergence (see section Statistical Mechanics page 3542) of the prior from the posterior.

Definitions (#5.7.141):

D1. A distribution is named a "flat prior", if its precision is zero or variance is infinite (in bayesian inference the "precision" is by definition the inverse of the variance).

D2. A distribution is named a "hard prior", if its precision is infinite or variance is zero (in bayesian inference the "precision" is by definition the inverse of the variance).

D3. A distribution is named a "soft prior", if its precision or variance are non-zero and finite (in bayesian inference the "precision" is by definition the inverse of the variance).

D4. A distribution is named an "empirical prior", if it has been derived from empirical data.

D5. A distribution is named an "theoretical prior", if it was specified without regard from empirical data.

5.7.9.2.2 Normal prior conjugate to Normal likelihood

We will focus here only on the case of the unknown mean because in practice it is the most used one (as far as we know) and it is also according to our personal point of view the only case that is intuitive to explain pedagogically speaking...

Let us consider that we want to make inference on the mean. We have the presumption that the measured random variable y probably follows a Normal distribution of mean and standard deviation $\mathcal{N}(y|\mu,\sigma)$ (i.e. the likelihood of y) and with the prior that μ follows a Normal distribution $\mathcal{N}(\mu_0,\sigma_0)$, which can be considered as a good choice as long as the possible values of μ correspond to the definition domain of the Normal distribution.

We have then (remember that in the prior distribution it is the parameter of interest which is the random variable!):

$$
\begin{aligned}
\pi(\mu|\vec{y},\sigma) &\propto P(\vec{y}|\mu,\sigma)P(\mu_0,\sigma_0) = \mathcal{N}(\vec{y}|\mu,\sigma)\mathcal{N}(\mu_0,\sigma_0)\\
&= \prod_{i=1}^{n}\left[\frac{1}{\sqrt{2\pi\sigma^2}}\exp\left(-\frac{(y_i-\mu)^2}{2\sigma^2}\right)\right]\cdot\frac{1}{\sqrt{2\pi\sigma_0^2}}\exp\left(-\frac{(\mu-\mu_0)^2}{2\sigma_0^2}\right)\\
&\propto \exp\left(\sum_{i=1}^{n}-\frac{(y_i-\mu)^2}{2\sigma^2}-\frac{(\mu-\mu_0)^2}{2\sigma_0^2}\right) = \exp\left(-\frac{1}{2}\left[\sum_{i=1}^{n}\frac{(y_i-\mu)^2}{\sigma^2}+\frac{(\mu-\mu_0)^2}{\sigma_0^2}\right]\right)\\
&= \exp\left(-\frac{1}{2\sigma^2\sigma_0^2}\left[\sigma_0^2\sum_{i=1}^{n}(y_i-\mu)^2+\sigma^2(\mu-\mu_0)^2\right]\right)\\
&= \exp\left(-\frac{1}{2\sigma^2\sigma_0^2}\left[\sigma_0^2\sum_{i=1}^{n}(y_i^2-2\mu y_i+\mu^2)+\sigma^2(\mu^2-2\mu\mu_0+\mu_0^2)\right]\right)\\
&= \exp\left(-\frac{1}{2\sigma^2\sigma_0^2}\left[\sigma_0^2\sum_{i=1}^{n}y_i^2-2\sigma_0^2\mu\sigma_{i=1}^{n}y_i+\sigma_0^2 n\mu^2+\sigma^2\mu^2-2\sigma^2\mu\mu_0+\sigma^2\mu_0^2\right]\right)\\
&= \exp\left(-\frac{1}{2\sigma^2\sigma_0^2}\left[\sigma_0^2\sum_{i=1}^{n}y_i^2-2\sigma_0^2\mu\frac{n}{n}\sum_{i=1}^{n}y_i+\sigma_0^2 n\mu^2+\sigma^2\mu^2-2\sigma^2\mu\mu_0+\sigma^2\mu_0^2\right]\right)\\
&= \exp\left(-\frac{1}{2\sigma^2\sigma_0^2}\left[\sigma_0^2\sum_{i=1}^{n}y_i^2-2\sigma_0^2\mu n\bar{y}+\sigma_0^2 n\mu^2+\sigma^2\mu^2-2\sigma^2\mu\mu_0+\sigma^2\mu_0^2\right]\right)
\end{aligned}
\tag{5.7.1595}
$$

We group and rearrange some terms:

$$
\begin{aligned}
\pi(\mu|\vec{y},\sigma) &\propto \exp\left(-\frac{1}{2\sigma^2\sigma_0^2}\left[\mu^2(\sigma^2+\sigma_0^2 n)-2\mu(\sigma^2\mu_0+\sigma_0^2 n\bar{y})+\sigma^2\mu_0^2+\sigma_0^2\sum_{i=1}^{n}y_i^2\right]\right)\\
&= \exp\left(-\frac{1}{2}\left[\mu^2\left(\frac{\sigma^2+\sigma_0^2 n}{\sigma^2\sigma_0^2}\right)-2\mu\left(\frac{\sigma^2\mu_0+\sigma_0^2 n\bar{y}}{\sigma^2\sigma_0^2}\right)+\frac{\sigma^2\mu_0^2+\sigma_0^2\sum_{i=1}^{n}y_i^2}{\sigma^2\sigma_0^2}\right]\right)\\
&= \exp\left(-\frac{1}{2}\left[\mu^2\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)-2\mu\left(\frac{\mu_0}{\sigma_0^2}+\frac{n\bar{y}}{\sigma^2}\right)+\frac{\mu_0^2}{\sigma_0^2}+\frac{\sum_{i=1}^{n}y_i^2}{\sigma^2}\right]\right)
\end{aligned}
\tag{5.7.1596}
$$

We now multiply the inside part of the square brackets by:

$$
\frac{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}
\tag{5.7.1597}
$$

in the purpose to eliminate the μ^2:

$$\begin{aligned}\pi(\mu|\vec{y},\sigma) &\propto \exp\left(-\frac{1}{2}\frac{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\left[\mu^2\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)-2\mu\left(\frac{\mu_0}{\sigma_0^2}+\frac{n\bar{y}}{\sigma^2}\right)+k\right]\right)\\ &=\exp\left(-\frac{1}{2}\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)\left[\mu^2\left(\frac{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)-2\mu\left(\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)+\underbrace{\frac{\dfrac{\mu_0^2}{\sigma_0^2}+\dfrac{\sum_{i=1}^n y_i^2}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}}_{:=k}\right]\right)\end{aligned} \tag{5.7.1598}$$

where k does not depend on μ. Let us continue...:

$$\begin{aligned}\pi(\mu|\vec{y},\sigma) &\propto \exp\left(-\frac{1}{2}\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)\left[\mu^2-2\mu\left(\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)+k\right]\right)\\ &=\exp\left(-\frac{1}{2}\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)\left[\mu-\left(\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)\right]^2\right)\end{aligned} \tag{5.7.1599}$$

Assuming that it exist a k such that (...):

$$k=\left(\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)^2 \tag{5.7.1600}$$

Remark

In other words we have to check that when using this tool that:

$$\left(\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)^2=\frac{\dfrac{\mu_0^2}{\sigma_0^2}+\dfrac{\sum_{i=1}^n y_i^2}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}} \tag{5.7.1601}$$

The posterior distribution thus looks indeed like the appearance of a Normal law:

$$\pi(\mu|\vec{y},\sigma)\propto\exp\left(-\frac{1}{2}\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)\left[\mu-\left(\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}\right)\right]^2\right) \tag{5.7.1602}$$

Remark

At the opposite of our study of the beta-binomial posterior distribution, we will not here divide by the marginal distribution that is anyway just a normalization constant and doesn't really interest us for now for the practical application we will have much later in this textbook.

The mean and the variance of the posterior distribution are then, by analogy, equal to:

$$\begin{aligned}\mu_p&=\frac{\dfrac{\mu_0}{\sigma_0^2}+\dfrac{n\bar{y}}{\sigma^2}}{\dfrac{1}{\sigma_0^2}+\dfrac{n}{\sigma^2}}=\frac{\dfrac{\mu_0\sigma^2\sigma_0^2}{\sigma_0^2}+\dfrac{n\bar{y}\sigma^2\sigma_0^2}{\sigma^2}}{\sigma^2+\sigma_0^2n}=\frac{\mu_0\sigma^2+n\bar{y}\sigma_0^2}{\sigma^2+\sigma_0^2n}=\frac{\sigma^2}{\sigma^2+\sigma_0^2n}\mu_0+\frac{\sigma_0^2}{\sigma^2+\sigma_0^2n}n\bar{y}\\ \sigma_p^2&=\left(\frac{1}{\sigma_0^2}+\frac{n}{\sigma^2}\right)^{-1}=\frac{\sigma^2\sigma_0^2}{\sigma_0^2n+\sigma^2}\end{aligned} \tag{5.7.1603}$$

Let us analyse a little more closely how the average prior mean μ_0 and the posterior mean μ_p are related to each other:

$$\mu_p=\frac{\sigma^2}{\sigma^2+\sigma_0^2n}\mu_0+\frac{\sigma_0^2}{\sigma^2+\sigma_0^2n}n\bar{y} \tag{5.7.1604}$$

We can observe that when n increases, the empirical mean $\bar{y}$ (second term) dominates the prior mean μ_0. When the prior variance σ_0^2 decreases, the average a priori (first term) takes a predominant importance.

Recall that in practice the specialist will, based on his return of experience (REX), choose the prior $\{\mu_0,\sigma_0\}$ about μ_p (since that latter depends on them) and that the standard deviation σ is assumed to be known (it is the set of all these parameters that make a lot of practitioners prefer the frequentist approach...).

5.7.9.2.3 Binomial prior conjugate to Binomial likelihood

This case has been sent to us by a reader. We did agree do add it in the present book for two reasons! The first one is because the "conditional binomial" is an interesting case where the prior and likelihood are both discrete (and this is not always intuitive to deal with that), the second one is because it use a kind of notation that should be known to a maximum a people and we can encounter in other textbooks. Let's see that that!

Let X and Y be two random variables where Y is binomially distributed conditional on X:

$$Y\mid X\sim\text{Bin}(X,q) \tag{5.7.1605}$$

and X also follows a binomial distribution but with different success frequency:

$$X\sim\text{Bin}(n,p) \tag{5.7.1606}$$

Then, as we will prove it, the marginal distribution of Y unconditional on X is again a binomial distribution:

$$Y\sim\text{Bin}(n,pq) \tag{5.7.1607}$$

Indeed, to prove that remember we are interested in the probability that Y equals a number m. According to the law of marginal probability or the law of total probability, this probability can be expressed as:

$$P(Y=m)=\sum_{k=0}^{+\infty} P(Y=m \mid X=k)\cdot P(X=k) \tag{5.7.1608}$$

Since, by definitions of the prior and the likelihood, $P(X=k)=0$ when $k>n$ and $P(Y=m \mid X=k)=0$ when $k<m$, we have:

$$P(Y=m)=\sum_{k=m}^{n} P(Y=m \mid X=k)\cdot P(X=k) \tag{5.7.1609}$$

Now we can take the probability mass function of the binomial distribution (see section Statistics page 658) and plug it in for the terms in the sum above to get:

$$P(Y=m)=\sum_{k=m}^{n}\binom{k}{m}q^m(1-q)^{k-m}\cdot\binom{n}{k}p^k(1-p)^{n-k} \tag{5.7.1610}$$

Applying the binomial coefficient identity (see section Probabilities page 530):

$$\binom{n}{k}\binom{k}{m}=\binom{n}{m}\binom{n-m}{k-m} \tag{5.7.1611}$$

and rearranging the terms, we have:

$$P(Y=m)=\sum_{k=m}^{n}\binom{n}{m}\binom{n-m}{k-m}p^k q^m(1-p)^{n-k}(1-q)^{k-m} \tag{5.7.1612}$$

Now we partition $p^k=p^m\cdot p^{k-m}$ and pull all terms dependent on k out of the sum:

$$\begin{aligned}P(Y=m)&=\binom{n}{m}p^m q^m\sum_{k=m}^{n}\binom{n-m}{k-m}p^{k-m}(1-p)^{n-k}(1-q)^{k-m}\\&=\binom{n}{m}(pq)^m\sum_{k=m}^{n}\binom{n-m}{k-m}(p(1-q))^{k-m}(1-p)^{n-k}\end{aligned} \tag{5.7.1613}$$

Then we substitute $i=k-m$, such that $k=i+m$:

$$P(Y=m)=\binom{n}{m}(pq)^m\sum_{i=0}^{n-m}\binom{n-m}{i}(p-pq)^i(1-p)^{n-m-i} \tag{5.7.1614}$$

According to the binomial theorem (see section Calculus page 1364):

$$(x+y)^n=\sum_{k=0}^{n}\binom{n}{k}x^{n-k}y^k \tag{5.7.1615}$$

the sum in the prior-previous relation is therefore equal to:

$$\sum_{i=0}^{n-m}\binom{n-m}{i}(p-pq)^i(1-p)^{n-m-i}=((p-pq)+(1-p))^{n-m} \tag{5.7.1616}$$

Therefore:

$$\begin{aligned}P(Y=m)&=\binom{n}{m}(pq)^m\sum_{i=0}^{n-m}\binom{n-m}{i}(p-pq)^i(1-p)^{n-m-i}\\&=\binom{n}{m}(pq)^m(p-pq+1-p)^{n-m}\\&=\binom{n}{m}(pq)^m(1-pq)^{n-m}\end{aligned}\tag{5.7.1617}$$

which is the probability mass function of the binomial distribution with parameters n and pq, such that:

$$Y\sim\mathrm{Bin}(n,pq)\tag{5.7.1618}$$

5.7.9.2.4 Credibility Intervals

In Bayesian inference, a "credibility interval" also named "credible interval" is an interval within which an unobserved parameter value falls with a particular probability. It is an interval in the domain of a posterior probability distribution or a predictive distribution. The generalisation to multivariate problems is the credible region. Credible intervals are analogous to confidence intervals in frequentist statistics, although they differ on a philosophical basis: Bayesian intervals treat their bounds as fixed and the estimated parameter as a random variable, whereas frequentist confidence intervals treat their bounds as random variables and the parameter as a fixed value. Also, Bayesian credible intervals use (and indeed, require) knowledge of the situation-specific prior distribution, while the frequentist confidence intervals do not.

A Bayesian statistician would say that given his observed data, there is a 95% probability that the true value of θ falls within the credible region while the frequentist statistician would say there is a 95% cumulated probability that when he computes a confidence interval from data of this sort, the true value of θ will fall within it.

Technically the bayesian "credibility interval" of size $1-\alpha$ is an interval $[x_1, x_2]$, where:

$$\boxed{P(x_1 \leq \theta \leq x_2|D) = \int\limits_{x_1}^{x_2} \pi(p(\theta|D))\mathrm{d}\theta = 1-\alpha} \qquad (5.7.1619)$$

Note that it is the parameter and not the interval limits, conditioned on the data D, that is random in this framework. This makes a credibility interval more intuitive because now we can interpret $1-\alpha$ as a (posterior) probability given an observed data set. In the frequentist setting, a given confidence interval is either right or wrong since θ is fixed. The confidence level only tells us what proportion of confidence intervals would be correct if we would repeat our calculations using new independent samples from the same underlying distribution, which many non-statisticians find confusing.

Let us see a companion example well illustrated (by the way...) in our `R` companion book to get more intuition about different approach.

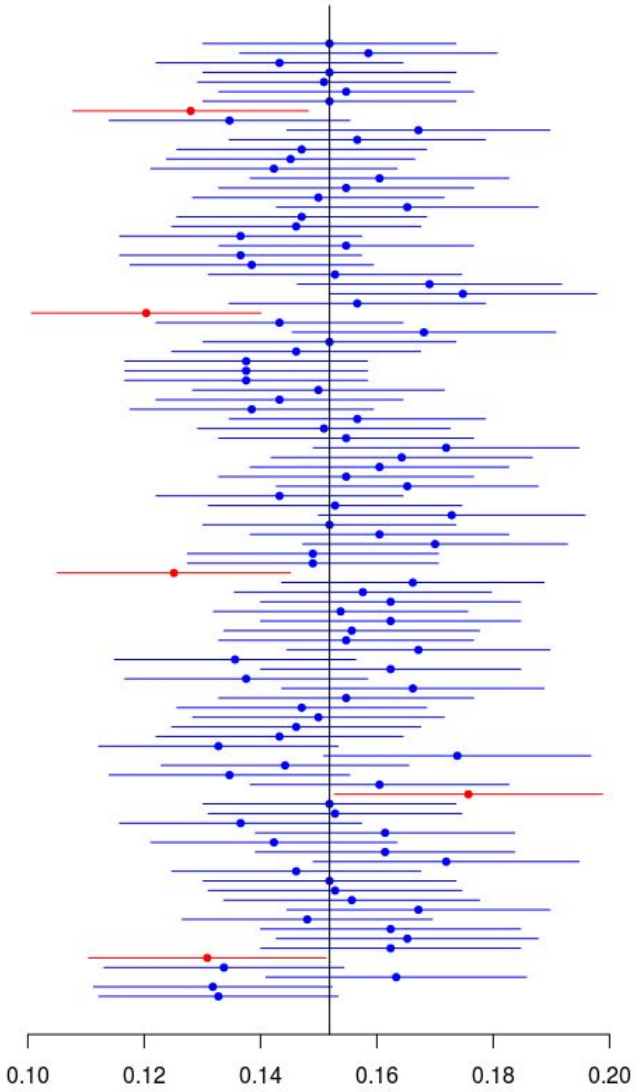
Consider a simple problem with Bernoulli trials in the field of insurance claims. We want to derive some confidence interval for the probability to claim a loss. There were $n=1047$ policies and in $y=159$ claims.

Consider the standard (frequentist) confidence interval of the proportion. What does that mean that:

$$\hat{p} - Z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \leq p \leq \hat{p} + Z_{\alpha/2}\sqrt{\frac{\hat{p}(1-\hat{p})}{n}} \qquad (5.7.1620)$$

is the (asymptotic) 95% confidence interval? The way we may see it is very simple. Let us generate some samples, of size n, with the same probability as the empirical one, i.e. $\hat{p}$ (which is the meaning of *from data of this sort*). For each sample, we compute the confidence interval with the relationship above. It is a 95% confidence interval because in 95% of the scenarios, the empirical value lies in the confidence interval.

If we write a R code that computes 100 of such intervals we get typically:



Now, what about the Bayesian credibility interval ? Assume that the prior distribution for the probability (denoted $\hat{p}$ in the frequentist framework) to claim a loss has a $\mathcal{B}(a,b)$ distribution. We have seen in the earlier above that, since the Beta distribution is the conjugate of the Bernoulli one, the posterior distribution will also be Beta. More precisely:

$$\pi(p(a,b)|\vec{y},n)=P_{a,b}\left(\sum_{i}^{N}y_i+a,nN-\sum_{i}^{N}y_i+b\right) \tag{5.7.1621}$$

Let us choose a uniform prior:

$$\pi(p(1,1)|\vec{y},n)=P_{1,1}\left(\sum_{i}^{N}y_i+1,nN-\sum_{i}^{N}y_i+1\right) \tag{5.7.1622}$$

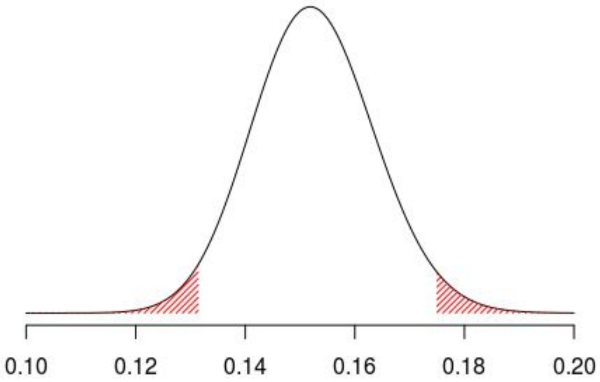
and let us consider we do the experiment only once ($N=1$):

$$\pi(p(1,1)|\vec{y},n)=P_{1,1}\left(y+1,n-y+1\right)=P_{1,1}\left(159+1,1047-159+1\right)=P_{1,1}(160,989) \tag{5.7.1623}$$

Based on that property, the credibility interval at 95% is based on quantiles of that (posterior) distribution such as:

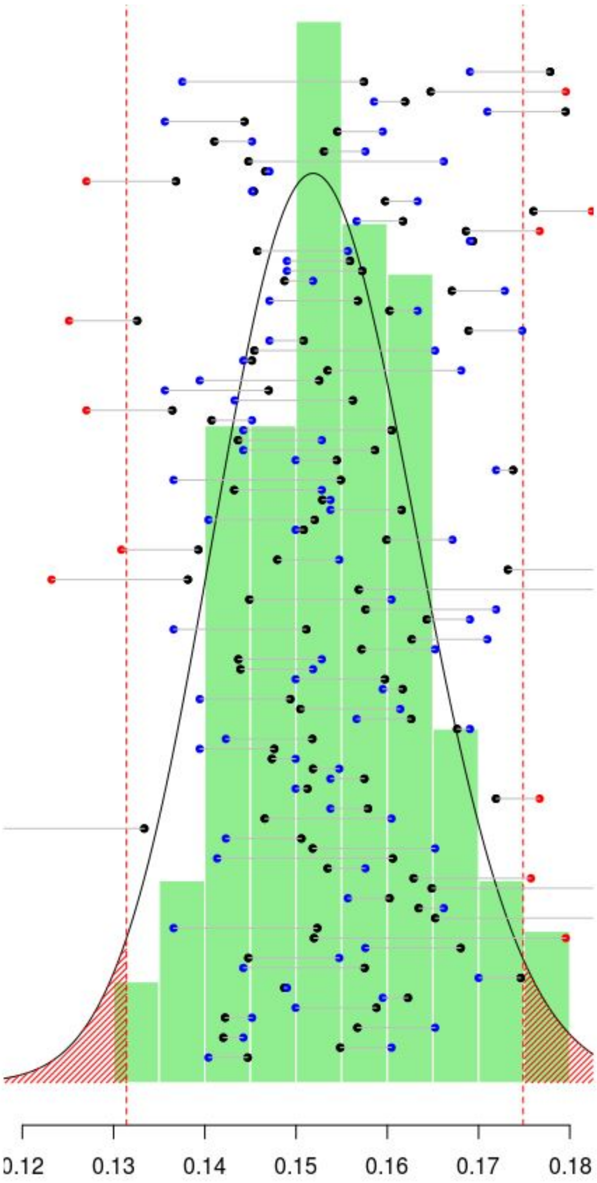
$$P(x_1 \leq \theta \leq x_2|D) = \int\limits_{x_1}^{x_2} \pi(p(\theta|D))\mathrm{d}\theta = \int\limits_{x_1}^{x_2} P_{1,1}(160, 989)\mathrm{d}\theta = 95\% \tag{5.7.1624}$$

and has the following shape if plotted with `R`:



It is straightforward with a statistical software to get the lower bound and upper bound quantile of the credibility interval.

We can now plot again 100 simulations but not generated using all the same estimated proportion as before, but using some possible probabilities (in green, below, we can visualize the histogram of those randomly chosen values), based on that posterior distribution (given the observations):



Here above there is 95% of probability that those empirical proportions lie in the credibility interval, defined using quantiles of the posterior distribution. We can actually visualize all those proportions: in black the proportion used to generate the sample, and then, in blue or red, the averages obtained on those simulated samples.

So what the reader has to remember is that in the Frequentist formulism (paradigm), the confidence intervals are random but the mean is not considered random but fixed. In Bayesian formulism (paradigm), the mean is considered a random variable but credible intervals are not random variables but are fixed!!!

5.7.9.2.5 Bayes Factor (BF)

In statistics, the use of "Bayes Factor" (i.e. "evidence" in experimental science) is a Bayesian alternative to classical p-value hypothesis testing (see page 948). Bayesian model comparison is a method of model selection based on Bayes factors. The models under consideration are statistical models. The aim of the Bayes factor is to quantify the support for a model over another, regardless of whether these models are correct. The technical definition of "support" in the context of Bayesian inference is described below.

Let us recall that according to Bayes' theorem, we can update prior probabilities of some model $\mathcal{M}$ ($P(\mathcal{M})$) to posterior probabilities ($P(\mathcal{M}|D)$) after observing some datum D by accounting for the probability of observing that datum given the model ($P(D|\mathcal{M})$, also known as the "likelihood"):

$$P(\mathcal{M}|D)=\frac{P(D|\mathcal{M})P(\mathcal{M})}{P(D)} \tag{5.7.1625}$$

Using this equation, We can compare the probability-odds of two models:

$$\frac{P(\mathcal{M}_1|D)}{P(\mathcal{M}_2|D)}=\frac{P(D|\mathcal{M}_1)}{P(D|\mathcal{M}_2)}\cdot\frac{P(\mathcal{M}_1)}{P(\mathcal{M}_2)} \tag{5.7.1626}$$

That latter is also often denoted:

$$\frac{P(H_0|D)}{P(H_1|D)}=\frac{P(D|H_0)}{P(D|H_1)}\cdot\frac{P(H_0)}{P(H_1)} \tag{5.7.1627}$$

Where the left-most term are the posterior odds, the right-most term are the prior odds, and the middle term is the Bayes factor:

$$\text{BF}_{12}=\frac{P(D|\mathcal{M}_1)}{P(D|\mathcal{M}_2)} \tag{5.7.1628}$$

That latter is also often denoted:

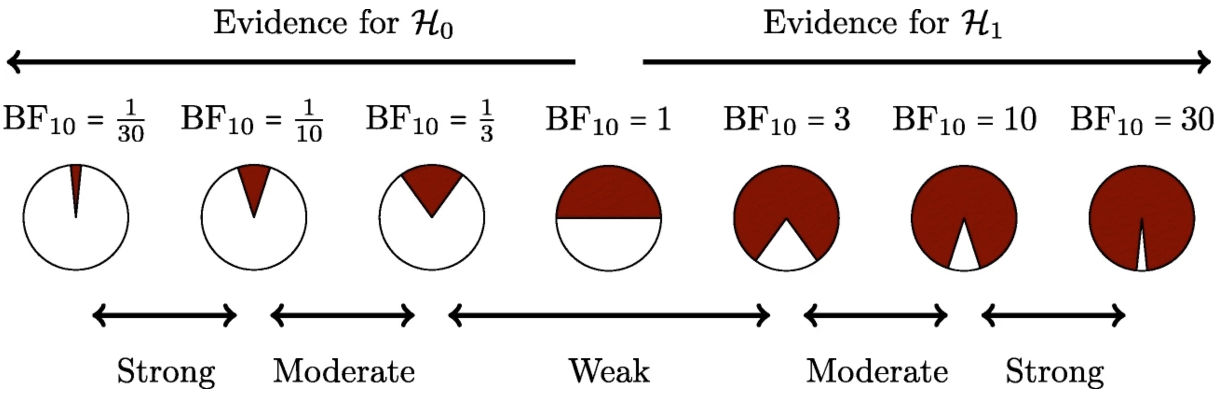
$$\text{BF}_{10}=\mathfrak{B}_{12}=\frac{P(D|H_0)}{P(D|H_1)} \tag{5.7.1629}$$

Thus, Bayes factors can be seen either as a ratio quantifying the relative probability of some observed data by two models as they can be computed by comparing the marginal likelihoods of the two models, or as the degree by which some prior beliefs about the relative credibility of two models are to be updated as they can be computed by dividing posterior odds by prior odds, as we will soon show it.

Obviously when the two models are equally probable a priori, so that $P(\mathcal{M}_1)=P(\mathcal{M}_2)$, the Bayes factor is equal to the ratio of the posterior probabilities of $\mathcal{M}_1$ and $\mathcal{M}_2$.

Bayes factor BF_{10}	**Label**
> 100	Extreme evidence for H_1
$30 - 100$	Very strong evidence for H_1
$10 - 30$	Strong evidence for H_1
$3 - 10$	Moderate evidence for H_1
$1 - 3$	Anecdotal evidence for H_1
1	No evidence
$1/3 - 1$	Anecdotal evidence for H_0
$1/3 - 1/10$	Moderate evidence for H_0
$1/10 - 1/30$	Strong evidence for H_0
$1/30 - 1/100$	Very strong evidence for H_0
$< 1/100$	Extreme evidence for H_0

Table 5.49: **Interpretations of the Bayes Factor**



Evidence for $\mathcal{H}_0$
Evidence for $\mathcal{H}_1$
$\mathrm{BF}_{10} = \frac{1}{30}$
$\mathrm{BF}_{10} = \frac{1}{10}$
$\mathrm{BF}_{10} = \frac{1}{3}$
$\mathrm{BF}_{10} = 1$
$\mathrm{BF}_{10} = 3$
$\mathrm{BF}_{10} = 10$
$\mathrm{BF}_{10} = 30$

Figure 5.168: **A graphical representation of a Bayes factor classification table from the JASP guidelines for conducting and reporting a Bayesian analysis**

✍**Example:**

Suppose we have a random variable that produces either a success or a failure. We want to compare a model $\mathcal{M}_1$ where the probability of success is $q = 1/2$, and another model $\mathcal{M}_2$ where θ is unknown and we take a prior distribution for θ that is uniform on $[0, 1]$. We take a sample of 200, and find 115 successes and 85 failures. The likelihood can be calculated according to the binomial distribution:

$$\binom{200}{115}\theta^{115}(1-\theta)^{85} \tag{5.7.1630}$$

Thus we have for $\mathcal{M}_1$:

$$P\left(X = 115 \mid \mathcal{M}_1\right) = \binom{200}{115}\left(\frac{1}{2}\right)^{200} = 0.005956\ldots \tag{5.7.1631}$$

whereas for $\mathcal{M}_2$ we have (the development involves the beta distribution):

$$\begin{aligned}P\left(X=115 \mid \mathcal{M}_2\right) &= \int\limits_0^1 \binom{200}{115}\theta^{115}(1-\theta)^{85}\mathrm{d}\theta = \binom{200}{115}\cdot\int\limits_0^1 \theta^{115}(1-\theta)^{85}\mathrm{d}\theta \\ &= \binom{200}{115}\cdot B(116,86) = \binom{200}{115}\cdot\frac{\Gamma(116)\cdot\Gamma(86)}{\Gamma(116+86)} \\ &= \frac{200!}{115!\cdot 85!}\cdot\frac{115!\cdot 85!}{201!} = \frac{1}{201} = 0.004975\ldots\end{aligned} \tag{5.7.1632}$$

The ratio is then:

$$\begin{aligned}\mathrm{BF}_{12} &= \frac{P\left(X=115 \mid \mathcal{M}_1\right)}{P\left(X=115 \mid \mathcal{M}_2\right)} = \frac{\mathcal{B}(k,N,0.5)}{\int B(\theta,1,1)\mathcal{B}(k,N,\theta)} \\ &= \frac{\binom{N}{k}0.5^k\left(1-0.5\right)^{N-k}}{\int\limits_0^1\binom{N}{k}\theta^k\left(1-\theta\right)^{N-k}\mathrm{d}\theta} = \frac{\binom{N}{k}0.5^N}{\binom{N}{k}\int\limits_0^1\theta^k\left(1-\theta\right)^{N-k}\mathrm{d}\theta} \\ &= \frac{0.5^N}{B(k+1,N-k+1)} \cong 1.197\ldots\end{aligned} \tag{5.7.1633}$$

which is "barely worth mentioning" even if it points very slightly towards $\mathcal{M}_1$.

A frequentist hypothesis test of $\mathcal{M}_1$ (here considered as a null hypothesis) would have produced a very different result. Such a test says that $\mathcal{M}_1$ should be rejected at the 5% significance level, since the probability of getting 115 or more successes from a sample of 200 if $\theta = 1/2$ is 0.0200, and as a two-tailed test of getting a figure as extreme as or more extreme than 115 is 0.0400. Note that 115 is more than two standard deviations away from 100. Thus, whereas a frequentist hypothesis test would yield significant results at the 5% significance level, the Bayes factor hardly considers this to be an extreme result. Note, however, that a non-uniform prior (for example one that reflects the fact that we expect the number of successes and failures to be of the same order of magnitude) could result in a Bayes factor that is more in agreement with the frequentist hypothesis test.

We can see in this example that the Bayes factor (evidence) of H_0 to H_1 is then the ratio of the likelihood under H_0 to the average likelihood under H_1 (or "odds" of H_0 to H_1)!

A classical likelihood-ratio test would have found the maximum likelihood estimate for θ, namely $115/200 = 0.575$, whence:

$$P\left(X=115 \mid \mathcal{M}_2\right) = \binom{200}{115}\theta^{115}(1-\theta)^{85} = 0.056991 \tag{5.7.1634}$$

(rather than averaging over all possible θ). That gives a likelihood ratio of 0.1045 and points towards $\mathcal{M}_2$.

$\mathcal{M}_2$ is a more complex model than $\mathcal{M}_1$ because it has a free parameter which allows it to model the data more closely. The ability of Bayes factors to take this into account is a reason why Bayesian inference has been put forward as a theoretical justification for and generalisation of Occam's razor, reducing Type I errors.

On the other hand, the modern method of relative likelihood takes into account the number of free parameters in the models, unlike the classical likelihood ratio. The relative likelihood method could be applied as follows. Model $\mathcal{M}_1$ has 0 parameters, and so its AIC (see section Numerical Methods page 6420) value is $2\cdot 0-2\cdot\ln(0.005956)=10.2467$. The model $\mathcal{M}_2$ has 1 parameter, and so its AIC value is $2\cdot 1-2\cdot\ln(0.056991)=7.7297$. Hence $\mathcal{M}_1$ is about $\exp\left((7.7297-10.2467)/2\right)=0.284$ times as probable as $\mathcal{M}_2$ to minimize the information loss. Thus $\mathcal{M}_2$ is slightly preferred, but $\mathcal{M}_1$ cannot be excluded!

Notice from the above example we can deduce even a more general definition of the Bayes factor:

$$\boxed{\text{BF}_{12}=\dfrac{P(D|\mathcal{M}_1)}{P(D|\mathcal{M}_2)}=\dfrac{\int P(D|\theta_1,\mathcal{M}_1)P(\theta_1|\mathcal{M}_1)\mathrm{d}\theta_1}{\int P(D|\theta_2,\mathcal{M}_2)P(\theta_2|\mathcal{M}_2)\mathrm{d}\theta_2}} \tag{5.7.1635}$$

Or written in the form of the null and alternative hypothesis:

$$\text{BF}_{10}=\dfrac{P(D|H_0)}{P(D|H_1)}=\dfrac{\int P(D|\theta_1,H_0)P(\theta_1|H_0)\mathrm{d}\theta_1}{\int P(D|\theta_2,H_1)P(\theta_2|H_1)\mathrm{d}\theta_2} \tag{5.7.1636}$$

The Bayes factor (evidence) of H_0 to H_1 is then ratio of the average likelihood under H_0 to the average likelihood under H_1 (or "odds" of H_0 to H_1)!

In most cases this factor has however to be calculated using Monte Carlo Markov Chains (see section Numerical Methods page **??**).
